A Companion to the Philosophy of Language

Blackwell Companions to Philosophy

This outstanding student reference series offers a comprehensive and authoritative survey of philosophy as a whole. Written by today's leading philosophers, each volume provides lucid and engaging coverage of the key figures, terms, topics, and problems of the field. Taken together, the volumes provide the ideal basis for course use, representing an unparalleled work of reference for students and specialists alike.

Already published in the series:

1. The Blackwell Companion to Philosophy, Second Edition
   Edited by Nicholas Bunnin and Eric Tsui-James
2. A Companion to Ethics
   Edited by Peter Singer
3. A Companion to Aesthetics, Second Edition
   Edited by Stephen Davies, Kathleen Marie Higgins, Robert Hopkins, Robert Stecker, and David E. Cooper
4. A Companion to Epistemology, Second Edition
   Edited by Jonathan Dancy, Ernest Sosa, and Matthias Steup
5. A Companion to Contemporary Political Philosophy (two-volume set), Second Edition
   Edited by Robert E. Goodin and Philip Pettit
6. A Companion to Philosophy of Mind
   Edited by Samuel Guttenplan
7. A Companion to Metaphysics, Second Edition
   Edited by Jaegwon Kim, Ernest Sosa, and Gary S. Rosenkrantz
8. A Companion to Philosophy of Law and Legal Theory, Second Edition
   Edited by Dennis Patterson
9. A Companion to Philosophy of Religion, Second Edition
   Edited by Charles Taliaferro, Paul Draper, and Philip L. Quinn
10. A Companion to the Philosophy of Language
    Edited by Bob Hale and Crispin Wright
11. A Companion to World Philosophies
    Edited by Eliot Deutsch and Ron Bontekoe
12. A Companion to Continental Philosophy
    Edited by Simon Critchley and William Schroeder
13. A Companion to Feminist Philosophy
    Edited by Alison M. Jaggar and Iris Marion Young
14. A Companion to Cognitive Science
    Edited by William Bechtel and George Graham
15. A Companion to Bioethics, Second Edition
    Edited by Helga Kuhse and Peter Singer
16. A Companion to the Philosophers
    Edited by Robert L. Arrington
17. A Companion to Business Ethics
    Edited by Robert E. Frederick
18. A Companion to the Philosophy of Science
    Edited by W. H. Newton-Smith
19. A Companion to Environmental Philosophy
    Edited by Dale Jamieson
20. A Companion to Analytic Philosophy
    Edited by A. P. Martinich and David Sosa
21. A Companion to Genethics
    Edited by Justine Burley and John Harris
22. A Companion to Philosophical Logic
    Edited by Dale Jacquette
23. A Companion to Early Modern Philosophy
    Edited by Steven Nadler
24. A Companion to Philosophy in the Middle Ages
    Edited by Jorge J. E. Gracia and Timothy B. Noone
25. A Companion to African-American Philosophy
    Edited by Tommy L. Lott and John P. Pittman
26. A Companion to Applied Ethics
    Edited by R. G. Frey and Christopher Heath Wellman
27. A Companion to the Philosophy of Education
    Edited by Randall Curren
28. A Companion to African Philosophy
    Edited by Kwasi Wiredu
29. A Companion to Heidegger
    Edited by Hubert L. Dreyfus and Mark A. Wrathall
30. A Companion to Rationalism
    Edited by Alan Nelson
31. A Companion to Pragmatism
    Edited by John R. Shook and Joseph Margolis
32. A Companion to Ancient Philosophy
    Edited by Mary Louise Gill and Pierre Pellegrin
33. A Companion to Nietzsche
    Edited by Keith Ansell Pearson
34. A Companion to Socrates
    Edited by Sara Ahbel-Rappe and Rachana Kamtekar
35. A Companion to Phenomenology and Existentialism
    Edited by Hubert L. Dreyfus and Mark A. Wrathall
36. A Companion to Kant
    Edited by Graham Bird
37. A Companion to Plato
    Edited by Hugh H. Benson
38. A Companion to Descartes
    Edited by Janet Broughton and John Carriero
39. A Companion to the Philosophy of Biology
    Edited by Sahotra Sarkar and Anya Plutynski
40. A Companion to Hume
    Edited by Elizabeth S. Radcliffe
41. A Companion to the Philosophy of History and Historiography
    Edited by Aviezer Tucker
42. A Companion to Aristotle
    Edited by Georgios Anagnostopoulos
43. A Companion to the Philosophy of Technology
    Edited by Jan-Kyrre Berg Olsen, Stig Andur Pedersen, and Vincent F. Hendricks
44. A Companion to Latin American Philosophy
    Edited by Susana Nuccetelli, Ofelia Schutte, and Otávio Bueno
45. A Companion to the Philosophy of Literature
    Edited by Garry L. Hagberg and Walter Jost
46. A Companion to the Philosophy of Action
    Edited by Timothy O'Connor and Constantine Sandis
47. A Companion to Relativism
    Edited by Steven D. Hales
48. A Companion to Hegel
    Edited by Stephen Houlgate and Michael Baur
49. A Companion to Schopenhauer
    Edited by Bart Vandenabeele
50. A Companion to Buddhist Philosophy
    Edited by Steven M. Emmanuel
51. A Companion to Foucault
    Edited by Christopher Falzon, Timothy O'Leary, and Jana Sawicki
52. A Companion to the Philosophy of Time
    Edited by Heather Dyke and Adrian Bardon
53. A Companion to Donald Davidson
    Edited by Ernest Lepore and Kirk Ludwig
54. A Companion to Rawls
    Edited by Jon Mandle and David Reidy
55. A Companion to W.V.O Quine
    Edited by Gilbert Harman and Ernest Lepore
56. A Companion to Derrida
    Edited by Zeynep Direk and Leonard Lawlor
57. A Companion to David Lewis
    Edited by Barry Loewer and Jonathan Schaffer
58. A Companion to Kierkegaard
    Edited by Jon Stewart
59. A Companion to Locke
    Edited by Matthew Stuart
60. The Blackwell Companion to Hermeneutics
    Edited by Niall Keane and Chris Lawn
61. A Companion to Ayn Rand
    Edited by Allan Gotthelf and Gregory Salmieri
62. The Blackwell Companion to Naturalism
    Edited by Kelly James Clark

VOLUME I

List of Contributors

Paul Artin Boghossian is Silver Professor of Philosophy at New York University and Director of its New York Institute of Philosophy. He has published many papers on the philosophy of mind and the philosophy of language, on such topics as color, rule-following, eliminativism, naturalism, self-knowledge, *a priori* knowledge, analytic truth, realism, and relativism. He is the author of *Fear of Knowledge* (Oxford University Press, 2006) and co-editor of *New Essays on the A Priori* (with Christopher Peacocke; Oxford University Press, 2000). A collection of his essays – *Content and Justification* – was published by Oxford University Press in 2008. A series of exchanges with Timothy Williamson, some previously published some new, on the analytic and the *a priori*, will appear from Oxford University Press in 2018.

Berit Brogaard is Director of the Brogaard Lab for Multisensory Research and Professor of Philosophy at the University of Miami. Her areas of research include perception, consciousness, emotions, philosophical psychology, semantics, and philosophical logic. She has written three books: *Transient Truths* (Oxford University Press, 2012), *On Romantic Love* (Oxford University Press, 2015), and *The Superhuman Mind* (Penguin, 2015), as well as over one hundred peer-reviewed articles.

John Collins is Professor of Philosophy at the University of East Anglia. He has published widely in the philosophy of language and mind, with especial reference to generative linguistics, and on the concept of truth. He is the author of *Chomsky: A Guide for the Perplexed* (Continuum, 2008) and *The Unity of Linguistic Meaning* (Oxford University Press, 2011), and co-editor of *Experimental Philosophy, Rationalism, and Naturalism* (with Eugen Fischer; Routledge, 2015).

Edward Craig is former Knightbridge Professor of Philosophy at the University of Cambridge, and has been a Fellow of the British Academy since 1993. He is the author of *The Mind of God and the Works of Man* (Oxford University Press, 1987) and *Knowledge and the State of Nature* (Oxford University Press, 1990), as well as articles on various topics in the theory of knowledge and philosophy of language. He is chief editor of the *Routledge Encyclopedia of Philosophy*.

Andy Egan is Professor of Philosophy at Rutgers University. He has held positions at the University of Michigan and the Australian National University. He attended graduate school at the University of Colorado and Massachusetts Institute of Technology. He works primarily in philosophy of language and philosophy of mind.

Kit Fine is University Professor and Silver Professor of Philosophy and Mathematics at New York University. His areas of interest include philosophical logic, philosophy of language, and metaphysics and his more recent books include *Modality and Tense* (Oxford University Press, 2005) and *Semantic Relationism* (Blackwell, 2007). He is a Fellow of the American Academy of Arts and Letters, and a corresponding Fellow of the British Academy.

Graeme Forbes is Professor of Philosophy at the University of Colorado at Boulder. He is the author of *Attitude Problems* (Oxford University Press, 2006) and the textbook *Modern Logic* (Oxford University Press, 1994). He works mainly in semantics, metaphysics, and logic, and has interests in compositionality, intensionality, modal metaphysics, and modal logic.

Anthony S. Gillies is Professor of Philosophy at Rutgers University, and previously taught at the University of Michigan, Harvard, and the University of Texas at Austin, and was White Distinguished Visiting Professor at the University of Chicago. His research interests are in philosophy of language: formal semantics and pragmatics; epistemology: belief revision, defeasible reasoning; philosophical logic; and decision/game theory.

Bob Hale is an Emeritus Professor at the University of Sheffield, and his main research interests are in the foundations of mathematics, and philosophy of logic and language. He is a member of the editorial board of *Philosophia Mathematica*, and is author of *Abstract Objects* (Blackwell, 1987) and *Necessary Beings* (Oxford University Press, 2013; revised 2nd edn, 2015); co-editor of *Reading Putnam* (with Peter Clark; Blackwell, 1994); co-editor of *Modality: Metaphysics, Logic, and Epistemology* (with Aviv Hoffmann; Oxford University Press, 2010); and co-author of *The Reason's Proper Study* (with Crispin Wright; Oxford University Press, 2001).

Anandi Hattiangadi has been Professor of Philosophy at Stockholm University and Pro Futura Scientia Fellow at the Swedish Collegium of Advanced Studies since 2013, before which she was a tutorial fellow of St Hilda's College, Oxford. She has research interests in the philosophy of mind and language, epistemology, metaphysics, and metaethics. Her publications include *Oughts and Thoughts: Rule-Following and the Normativity of Content* (Oxford University Press, 2007), as well as numerous articles on the normativity of meaning, content, and belief.

Jussi Haukioja is Professor of Philosophy at the Norwegian University of Science and Technology and editor of the volume *Advances in Experimental Philosophy of Language* (Bloomsbury, 2015). His research interests are in philosophy of language, philosophy of mind, and realism and anti-realism.

Jane Heal is Emeritus Professor of Philosophy at the University of Cambridge and a Fellow of St John's College. Her interests are mainly in philosophy of language and

philosophy of mind. Her previous publications include her book *Fact and Meaning* (Blackwell, 1989) and several journal articles in these areas. She was elected a Fellow of the British Academy in 1997.

Barry Loewer is Professor and Director of the Rutgers Center for Philosophy and the Sciences. His published work lies mainly in the philosophy of mind and psychology, the philosophy of quantum mechanics, and metaphysics, including the book *Why There is Anything Except Physics* (Oxford University Press, 2008).

Guy Longworth is Associate Professor in Philosophy at the University of Warwick. He works mainly in the philosophy of language and mind, including intersections with epistemology.

E. J. Lowe was Professor of Philosophy at the University of Durham, where he taught from 1980 until his death in 2014. He authored 11 books, including *Kinds of Being* (Blackwell, 1989) and *The Possibility of Metaphysics* (Oxford University Press, 1998), and also co-edited four volumes and wrote over two hundred articles for journals and edited collections.

Michael P. Lynch is Professor of Philosophy and Director of the Humanities Institute at the University of Connecticut. He is the author or editor of seven books including *In Praise of Reason* (MIT Press, 2012), *Truth as One and Many* (Oxford University Press, 2009), and *True to Life* (MIT Press, 2004). His research interests lie in pursuing problems within the intersection of epistemology, metaphysics, and the philosophy of language.

Penelope Mackie is Associate Professor and Reader in Philosophy at the University of Nottingham. She is the author of *How Things Might Have Been: Individuals, Kinds, and Essential Properties* (Oxford University Press, 2006) and of a number of articles on topics in metaphysics, including causation, modality, material constitution, free will, and the fixity of the past.

Aidan McGlynn is a lecturer in Philosophy at the University of Edinburgh. He recently completed a series of papers and a monograph on knowledge first approaches to epistemology and the philosophies of language and mind. Since then, he has been working on evidence, first-person thought and self-knowledge, pornography, epistemic injustice, silencing, and objectification.

Andrew McGonigal holds a visiting professorship in philosophy at Washington and Lee University. Before taking up the position, he taught for 12 years at the University of Leeds. He is a co-editor of the *Routledge Companion to Metaphysics*, and in 2014–2015 was awarded a Society Fellowship at the Society for the Humanities at Cornell.

Alexander Miller is Professor of Philosophy and chair of the Department of Philosophy at the University of Otago. He works mainly on the philosophy of language and mind, metaphysics, and metaethics. His books include *Contemporary Metaethics: An Introduction Revised and Expanded* (2nd edn, Polity Press, 2013) and *Philosophy of Language Revised and Expanded* (2nd edn, Routledge, 2007). He is co-editor of *Rule-Following and Meaning* (with Crispin Wright; Acumen, 2002).

Richard Moran is Professor of Philosophy at Harvard University, having previously taught at Princeton University. He works primarily in the areas of moral psychology, the philosophy of mind and language, aesthetics and the philosophy of literature, and the later Wittgenstein. He has published papers on metaphor, on imagination and emotional engagement with art, and on the nature of self-knowledge. His book, *Authority and Estrangement: An Essay on Self-Knowledge*, was published by Princeton University Press in 2001.

Michael Morris is Professor of Philosophy at the University of Sussex. He is the author of *The Good and the True* (Oxford University Press, 1992), *An Introduction to the Philosophy of Language* (Cambridge University Press, 2007), and *Wittgenstein and The Tractatus* (Routledge, 2008), as well as papers in the philosophy of language and the philosophy of art.

Julien Murzi completed his PhD at the University of Sheffield in October 2010. He is Assistant Professor at the University of Salzburg, having previously been a post-doctoral fellow at the Munich Center for Mathematical Philosophy (of which he continues to be an external member) and Lecturer in Philosophy at the University of Kent. He has published papers on inferentialism, logical consequence, the semantic paradoxes, the realism/anti-realism debate, and the open future.

Bernhard Nickel is Professor of Philosophy at Harvard University. He works mainly in philosophy of language and semantics, with interests in metaphysics, the philosophy of science, and philosophy of mind. He is the author of *Between Logic and the World* (Oxford University Press, 2016), which presents a theory of generics and genericity.

Christian Nimtz is Professor of Theoretical Philosophy at Bielefeld University in Germany. His interests lie mainly in the philosophy of language, modal epistemology, and meta-philosophy. He has worked on natural kind terms, modal knowledge, thought experiments, and conceptual analysis.

Harold Noonan is Professor of Mind and Cognition at the University of Nottingham. He has published seven books, including *Hume* (One Word Publishers, 2007) and *Frege* (Polity Press, 2001), as well as various articles on topics in the philosophy of mind, philosophy of language, and philosophy of logic.

Christopher Peacocke is Johnsonian Professor of Philosophy at Columbia University, and was previously Waynflete Professor of Metaphysical Philosophy at the University of Oxford, where he also held a Leverhulme Personal Research Professorship. He is the author of several books, most recently *The Mirror of the World: Subjects, Consciousness, and Self-Consciousness* (Oxford University Press, 2014), and of papers in the philosophy of language, mind, psychology, and logic. He is a Fellow of the British Academy and the American Academy of Arts and Sciences.

John Perry is the Waldgrave Stuart Professor of Philosophy Emeritus at Stanford University and Distinguished Professor of Philosophy Emeritus at the University of California, Riverside. He is co-director of the Center for the Explanation of Consciousness at the Center for the Study of Language and Information. He has authored several books, including the second

enlarged edition of *Reference and Reflexivity* (CSLI Publications, 2012) and various articles on the philosophy of language. He also co-hosts a weekly talk show called *Philosophy Talk*.

James Pryor is a Professor of Philosophy at New York University. His research focus is epistemology, formal semantics (especially issues at the intersection of philosophy, linguistics, and computer science), philosophy of mind, and related issues.

Mark Richard is Professor of Philosophy at Harvard University. He works in the philosophy of language, epistemology, and metaphysics, as well as in mathematical and intensional logic, philosophy of logic, and philosophy of mind. He owns a Fender Stratocaster but sadly at the moment lacks a dog. He is the author of numerous articles and books, most recently *Meaning in Context, Volume I: Context and the Attitudes* (Oxford University Press, 2013) and *Meaning in Context, Volume II: Truth and Truth Bearers* (Oxford University Press, 2015).

Ian Rumfitt is a Senior Research Fellow of All Souls College, Oxford. He works mainly in the philosophy of language, philosophical logic, and the philosophy of mathematics. His book *The Boundary Stones of Thought* (Oxford University Press, 2015) investigates conflicts between rival logical systems and how they might be rationally resolved.

Mark Sainsbury is Professor of Philosophy at the University of Texas at Austin, having formerly taught at King's College London. He is the author of *Russell* (Routledge, 1979), *Paradoxes* (Cambridge University Press, 1987), *Logical Forms* (Blackwell, 1991), *Departing From Frege* (Routledge, 2002), *Reference Without Referents* (Oxford University Press, 2005), and *Fiction and Fictionalism* (Routledge, 2009), and co-author of *Seven Puzzles of Thought and How to Solve Them: An Originalist Theory of Concepts* (with Michael Tye; Oxford University Press, 2013). His *Thinking About Things* is due out from Oxford University Press in 2017.

Stephen Schiffer is Silver Professor of Philosophy at New York University. He works primarily in philosophy of language, philosophy of mind, and metaphysics. He is the author of numerous articles and of three books: *Meaning* (Oxford University Press, 1972), *Remnants of Meaning* (MIT Press, 1987), and *The Things We Mean* (Oxford University Press, 2003). He is a Fellow of the American Academy of Arts and Sciences.

Peter Schulte teaches philosophy at the Bielefeld University. His areas of specialization are philosophy of mind, metaphysics, philosophy of language, metaethics, and free will.

Patrick Shirreff received a BA (Hons) from the University of Toronto in 2010 and is an ABD at the University of Michigan. His research focuses on the intersection of philosophy of language and epistemology. Specifically, Shirreff is interested in the semantics of epistemic language and what this semantic theorizing can show us about epistemic theorizing.

John Skorupski is Professor Emeritus of Moral Philosophy at the University of St Andrews. His current interests are in moral and political philosophy, metaethics and epistemology, and the history of nineteenth- and twentieth-century philosophy. His most recent books are *The Domain of Reasons* (Oxford University Press, 2010) and *Why Read Mill Today?* (Routledge, 2006).

Robert Stalnaker is Professor of Philosophy in the Department of Linguistics and Philosophy at MIT. His teaching and research interests are in philosophical logic, philosophy of mind, and the philosophy of language. He is the author of *Inquiry* (MIT Press, 1984), and of various articles on intentionality and the foundations of semantics and pragmatics. He also has two volumes of collected papers: *Context and Content* (Oxford University Press, 1999) and *Ways a World Might Be* (Oxford University Press, 2003).

Jason Stanley is Jacob Urowsky Professor of Philosophy at Yale University. His interests include the philosophy of language, the history and philosophy of logic, the history of analytic philosophy, epistemology, and the philosophy of mind. He is the author of four books, most recently *How Propaganda Works* (Princeton University Press, 2015) and *Know How* (Oxford University Press, 2011).

Florian Steinberger joined the Department of Philosophy at the Birkbeck University of London in 2015, prior to which he was Assistant Professor in Philosophy and Language at the Ludwig-Maximilians University in Munich and the Munich Center for Mathematical Philosophy. His main research interests include parts of epistemology, normativity, and the philosophies of logic and language.

Charles Travis is Professor Emeritus at King's College London and a Professor Afiliado in the Faculdade de Letras at the University of Porto. He has published extensively on the philosophy of language and the philosophy of mind. He is the author of many books, including *Perception: Essays After Frege* (Oxford University Press, 2013) and *Objectivity and the Parochial* (Oxford University Press, 2011), together with numerous articles.

Ralph C. S. Walker is Emeritus Fellow at Magdalen College, Oxford. His research interests are in Immanuel Kant, ethics, philosophy of religion, truth, and justification of beliefs. His publications include *Kant* (Oxford University Press, 1978) and *The Coherence Theory of Truth* (Routledge, 1988).

Brian Weatherson is the Marshall M. Weinberg Professor of Philosophy at the University of Michigan, Ann Arbor. He works on epistemology, especially on issues at the intersection of ethics and epistemology, and issues at the interface between formal and traditional approaches to epistemology, as well as on many topics in philosophy of language.

Daniel Wee teaches philosophy at the Universiti Brunei Darussalam, having completed his PhD on rule-following and communitarianism at the University of Otago in 2016. His research interests are in philosophy of language, ethics, meta-philosophy, and critical thinking.

Bernhard Weiss is Professor of Philosophy at the University of Cape Town. He is the editor of the collection *Dummett on Analytical Philosophy* (Palgrave Macmillan, 2015), and author of two books: *Michael Dummett* (Acumen, 2002) and *How To Understand Language* (Acumen, 2010). His areas of interest concern philosophies of language, logic and mathematics, and realism and anti-realism.

David Wiggins is Professor Emeritus of Philosophy at Oxford. He was previously Professor of Philosophy at Birkbeck College, London, and before that Fellow and Praelector of University College, Oxford. His principal publications are *Sameness and Substance* (Blackwell, 1980) and *Needs, Values, Truth* (2nd edn, Blackwell, 1998), as well as *Ethics: Twelve Lectures on the Philosophy of Morality* (Cambridge University Press, 2006) and *Sameness and Substance Renewed* (Cambridge University Press, 2001). He is a Fellow of the British Academy.

Timothy Williamson has been Wykeham Professor of Logic at Oxford since 2000, and previously taught logic and metaphysics at the University of Edinburgh. His main research interests are in philosophical logic, epistemology, metaphysics, and philosophy of language. He is the author of *Identity and Discrimination* (Blackwell, 1990), *Vagueness* (Blackwell, 1994), *Knowledge and its Limits* (Oxford University Press, 2000), and most recently *Tetralogue* (Oxford University Press, 2015), as well as articles in journals of philosophy and logic.

Crispin Wright is Professor of Philosophy at New York University and Professor of Philosophical Research at the University of Stirling. His books include *Wittgenstein on the Foundations of Mathematics* (Harvard University Press, 1980), *Frege's Conception of Numbers as Objects* (Humanities Press, 1983), *Truth and Objectivity* (Harvard University Press,1992), *Realism, Meaning and Truth* (2nd edn, Blackwell, 1993), *The Blackwell Companion to Philosophy of Language* (with Bob Hale; Blackwell, 1997), *The Reason's Proper Study* (with Bob Hale; Clarendon Press, 2001), *Rails to Infinity* (Harvard University Press, 2001), and *Saving the Differences* (Harvard University Press, 2003). Two collections of his papers, *The Riddle of Vagueness* and *Imploding the Demon*, are currently in preparation.

Preface to the Second Edition

We have taken advantage of Wiley-Blackwell's generous offer to publish a second and significantly expanded version of the first (1997) edition of the *Companion* to update the original chapters and to publish a range of new chapters that both broaden and deepen the coverage provided in the earlier edition.

Of the 25 chapters in the first edition, 21 have been updated, either by the original author or by a new author specifically commissioned for that purpose. Many updates take the form of postscripts to the originals, although a few simply revise and update the text from the first edition. The first edition chapter on intention and convention has been replaced by an entirely new chapter on the topic by Stephen Schiffer. The only first edition chapters reprinted unchanged are those by Christopher Peacocke, Robert Stalnaker, and Jason Stanley.

In addition to the 21 updates to the first edition and Schiffer's new chapter on intention and convention, there are 16 wholly new chapters covering both foundational issues and issues relating to specific linguistic phenomena. We have retained the tripartite structure of the original and have added a few new entries to the glossary.

We're grateful to all of our authors, both old and new, for their excellent chapters, updates, and glossary entries, and to Mark Cooper and Allison Koska at Wiley-Blackwell for their support and patience. Thanks, too, to Marielle Suba for her work on formatting final versions of the chapters, and to Marguerite Nesling and Giles Flitney for assistance with copy-editing and proofreading.

Bob Hale, Alex Miller, and Crispin Wright

Preface to the First Edition

The recent proliferation of dictionaries and encyclopedias of philosophy has resulted in no shortage of companionship for the philosophical tourist whose desire is merely for a short excursion. Our *Companion* is intended as a guide for a more determined and ambitious explorer. Thus this is no alphabetized compendium of brief statements of the principal theoretical positions, concepts, and protagonists in recent and contemporary philosophy of language, but comprises, rather, 25 extended essays on a nucleus of the most central issues in the field, each of which has seen and continues to see important work.

All of our contributors are active in research on their selected topics. Each was invited to contribute a chapter somewhat along the lines of the *State of the Art* series which *Mind* initiated in the mid-1980s: a survey and analysis of recent trends in work on the topic in question, offering a bibliography of the more important literature and incorporating a substantial research component. Accordingly, these are chapters for a philosophically experienced – advanced undergraduate, graduate, or professional – readership. Each chapter is, however, written so as to presuppose a minimum of prior knowledge of its specific subject-matter, and so offers both a self-contained overview of the relevant issues and of the shape of recent discussion of them and, for readers who want it, an up-to-date preparation for extended study of the topic concerned. There are, naturally, numerous points of connection among the chapters, some of which will be obvious enough from their titles or from a quick glance at their opening sections; others have been indicated by explicit cross-referencing. We have attempted, in the glossary, to provide concise explanations of all of the more important technical or semi-technical terms actually employed in the various chapters, and of a good number of other terms of art which, though not actually used by any of our contributors, figure centrally in other published work on the issues. The result, as we hope, is an anthology which will both stimulate research in the philosophy of language and provide an up-to-date textbook for its advanced teaching for many years to come.

Few would now subscribe to the idea which prevailed for a while in some Anglo-American philosophical circles during the 1970s, that the philosophy of language is First Philosophy, and that great issues in, for instance, metaphysics, epistemology, and the philosophy of mind, are to be resolved by, in effect, recasting them as matters for treatment within the theory of meaning. But there is no doubt that philosophy of language continues to occupy a position of central importance in contemporary philosophy, nor that some of

the best and most influential philosophical writing of the latter half of this century, by some of the foremost philosophical thinkers of our time, has been accomplished in this area. The threefold division into which we have organized the chapters closely reflects the landscaping which these leading authors have given to the subject. Part I, on *Meaning and Theories of Meaning,* comprises chapters which are all concerned, in one way or another, with issues connected to the nature of language mastery that have loomed large in the writings of Davidson, Dummett, and Grice. Part II, on *Language, Truth, and Reality*, pivots around more metaphysical issues to do with meaning: with the ongoing debate about meaning-skepticism that has drawn on the writings of Kripke, Putnam, Quine, and Wittgenstein, and with the connections between issues to do with meaning and the various debates about realism, whose excavation has been led by Dummett. Finally, Part III, on *Reference, Identity, and Necessity*, focuses on issues which take center stage in – or at least, loom large in the stage-setting for – Kripke's *Naming and Necessity*. Together, the three parts cover almost every topic that anyone familiar with contemporary work in the philosophy of language would expect to receive extensive discussion in a volume of this kind. There are nevertheless some vacancies which we would have liked, ideally, to have filled. There is, for example, no chapter focusing on the concept of a *criterion* which the first generation of commentary elicited from Wittgenstein's *Philosophical Investigations*, nor – perhaps more grievous – did we succeed in the end in commissioning a suitable study of semantic externalism or of notions of supervenience.

It remains to express our gratitude to our contributors, both for their patience with our editorial suggestions and for the excellence of their contributions and valuable assistance with glossary entries; to our publishers for bearing with us while we put together a volume which has been inevitably subject to many delays; to the secretarial staff of the Philosophy Departments of the Universities of St Andrews and Glasgow for assistance with the preparation and standardization of typescripts; and to each other.

Bob Hale and Crispin Wright

PART I

Meaning and Theories of Meaning

1

Metaphysics, Philosophy, and the Philosophy of Language

MICHAEL MORRIS

1 Two Positions

Michael Dummett famously declared (Dummett, 1993, p. 4):

> What distinguishes analytical philosophy, in its diverse manifestations, from other schools is the belief, first, that a philosophical account of thought can be attained through a philosophical account of language, and, secondly, that a comprehensive account can only be so attained.

He had earlier claimed (Dummett, 1978e, p. 458):

> Only with Frege was the proper object of philosophy finally established: namely, first, that the goal of philosophy is the analysis of the structure of *thought*; secondly, that the study of *thought* is to be sharply distinguished from the study of the psychological process of *thinking*; and, finally, that the only proper method for analysing thought consists in the analysis of *language*.

In sharp contradistinction, Timothy Williamson, taking metaphysics to be "central" to philosophy (a point to note before moving on), asserts (Williamson, 2007, pp. 18–19):

> Much contemporary metaphysics is not primarily concerned with thought or language at all. Its goal is to discover what fundamental kinds of thing there are and what properties and relations they have, not to study the structure of our thought about them – perhaps we have no thought about them until it is initiated by metaphysicians. Contemporary metaphysics studies substances and essences, universals and particulars, space and time, possibility and necessity. Although nominalist or conceptualist reductions of all these matters have been attempted, such theories have no methodological priority and generally turn out to do scant justice to what they attempt to reduce.

We seem to have here the following stark contrast: Dummett thinks understanding language is central to philosophy, whereas Williamson apparently does not. Dummett is

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

endorsing some form of what has been known as the "linguistic turn"[1] – the dominant tendency in English-speaking philosophy in the middle of the twentieth century – whereas Williamson is rejecting it.

I offer here a selective critical history in which I trace the difference between the tendency which Dummett represents and the philosophers among whom Williamson is naturally placed to a difference in metaphysics which has much longer roots.[2] In fact it turns out that those who reject the tendency Dummett represents also often give a central role to the philosophy of language. This is questionable too, though on other grounds.

2 Dummett and Thought

I will not dwell on the fact that Dummett counts it a distinctive mark of *analytic* philosophy in particular to give priority to the philosophy of language. (I take it that he is here aiming to contrast analytic philosophy both with the philosophy which preceded it and against which it was a reaction (most obviously Hegelianism in various forms), and with the older philosophers in the phenomenological tradition (who may be said to give priority instead to a proper attentiveness to the actual character of experience).) Nor will I linger over the fact that his characterization of analytic philosophy is odd from a classificatory point of view, since it both excludes some of the most prominent analytic philosophers – Dummett himself acknowledges that Gareth Evans is left out, only counting as analytic "as belonging to this tradition" (Dummett, 1993, p. 4) – and includes some philosophers it would be odd to call analytic (Derrida is the obvious example here). I will simply take him here to be declaring in another way his view of how philosophy *ought* to be done.

When we set that issue aside, what is most immediately striking about what Dummett says is not the importance he gives to the philosophy of language, but the importance he gives to providing a philosophical account of *thought*. It seems more natural to think that the business of philosophy is to make sense, in the first instance, not of thought, but of the *world* – which is to say, of the *objects* of thought. Of course thought itself may be thought about, and so itself be an object of thought, but it is natural to expect philosophy to be concerned with thought chiefly when it is the object of thought, which is not all that often. Why, then, does Dummett give such central importance to the task of making sense of thought?

His official reason appears to be that "Thoughts [in the sense of *what is thought*] differ from all else that is said to be among the contents of the mind in being wholly communicable" (Dummett, 1978e, p. 442). But we have seen that Dummett takes recognizing the importance of the philosophy of language to depend on the antecedent recognition of the importance of an understanding of thought, whereas this remark makes thought important only in so far as we are interested in communication – an interest which looks as if it depends on an interest in language.

We might suggest that the importance Dummett gives to thought depends on his interest in Frege.[3] In Frege's later philosophy, thoughts – understood as the senses of sentences, what are expressed by sentences – might be taken to be the principal focus of his concerns; and thoughts are certainly the primary bearers of truth for Frege (Frege, 1977). But again it is hard to see how this can be the ultimate explanation of Dummett's focus on thought. First, Frege seems to be concerned with thought only because he is already concerned with

language, so, as before, this fails to explain why Dummett should want to explain the importance of the philosophy of language in terms of the importance of understanding thought. And second, the first and most striking case where Frege seems to give language a central importance is a case in which a claim about language is used directly to make a claim about the nature of the *world*, without any detour through thought. One of Frege's crucial claims in the *Foundations of Arithmetic* is that numbers are objects (Frege, 1953). It is already clear that Frege takes numbers to belong to the world – to what would later be counted as the realm of reference – rather than to anything psychological (and at this point he had not isolated a distinct realm of sense). The claim that they are objects depends just on two further claims: first, that objects are nothing but the referents of singular terms; and, second, that number words are best understood as singular terms. This is a case of a philosophical account of language being taken to be the only way of achieving a philosophical account of the *world*, not of thought.

So if we are to make sense of Dummett's giving such central importance to the task of making sense of thought we need to look elsewhere. I think the place to look is obvious enough, when we think of Dummett's links to verificationism and to other strands of the empiricist tradition.[4] I suggest that the ultimate source of the kind of role Dummett gives to thought is Hume's skeptical view of necessity, with its famous consequences for metaphysics.[5]

Hume's view depends on empiricism about our grip on reality, combined with a particular theory of perception which he shared, in general outline at least, with the other classical empiricists, and with most other philosophers down to the middle of the twentieth century. His general empiricism requires that if we are to have any knowledge of something in the world – something which is, in some sense, independent of us – it must be made available to us through sense-perception. (This also, of course, limits what can be included in the world – in what is truly independent of us – at least in so far as we can have knowledge of it.) So if necessity and possibility (the necessity and possibility which concern us, at least) are to be in the world – to be, in the relevant sense, independent of us – they have to be made available to us through perception. And conversely, if necessity and possibility are not made available to us through perception, then when we take ourselves to be thinking of necessity and possibility we cannot be thinking of something which is properly independent of us. The theory of perception adds further constraints to this general empiricist picture in two stages. It first limits what can genuinely be perceived to what can be constructed from what is distinctively available to each of the senses (color to sight, sound to hearing, and so on). It then limits what can genuinely be perceived still further by insisting that what is genuinely or immediately perceived must be constant between genuine, veridical perception, on the one hand, and illusion or hallucination, on the other (so if something could have looked the same even if it hadn't had some feature, then it is impossible genuinely or immediately to perceive that it has that feature). The theory of perception makes it hard to believe that necessity and possibility can be made available to us through perception, and the general empiricism then means that what we think of when we take ourselves to be thinking of necessity and possibility cannot be independent of us in the way which is required for them to be real, or really part of the world. The conclusion Hume draws seems inescapable (Hume, 1978, p. 165):

> Upon the whole, necessity is something, that exists in the mind, not in objects; nor is it possible for us ever to form the most distant idea of it, consider'd as a quality in bodies.

As this brief quotation makes clear, Hume contrasts what is genuinely in the world, in some sense independent of us – in this case as a 'quality in bodies' – with what depends on us. (There may be a question whether this contrast can be maintained consistently with all of the rest of his philosophy, but we do not need to pursue that question here.) If realism about something is the view that its nature is independent of us and of the way we think about it or represent it, and the correlative anti-realism is the rejection or non-acceptance of realism, Hume is naturally seen as favoring a general realism about the world – at least relatively speaking[6] – while adopting an anti-realist view about modality in particular: the world is real and independent of us, but possibility and necessity are not strictly part of the world.

This contrast, in turn, looks as if it forces us to accept a sharp division between kinds of discipline or enquiry, if we want to allow that there are any necessary truths at all. On the one hand, there are those disciplines or investigations which provide knowledge about the world. On the other hand, there are those disciplines or investigations which enable us to draw conclusions of necessity and possibility. The Humean combination of realism about the world and anti-realism about modality requires that these two kinds of discipline are fundamentally distinct: in so far as some discipline enables us to draw modal conclusions, it cannot be concerned with the real world; and in so far as it provides knowledge of the real world, its conclusions cannot be modal. This is, in effect, Hume's Fork.[7]

This sharp distinction looks as if it causes deep problems for metaphysics, on a natural understanding of metaphysics. On that natural understanding, the central business of metaphysics is to discover how the world must be – to discover its necessary features (see, e.g., Kant, 1997, B19–24, and Williamson, 2007, p. 134). On this conception, it is essential to metaphysics that it provide us with knowledge of truths which are both genuinely about the world and necessary. Hume's view then makes metaphysics impossible, as he noted with some glee (Hume, 1975, p. 165). Kant recognized this too, and attempted a defense of metaphysics in the face of the threat of Humeanism (Kant, 1997, B19–20). The Humean problem arises from the contrast between realism about the world and anti-realism about modality. Kant's solution – at least, on an orthodox interpretation – is to remove the contrast by weakening the realism about the world. The essence of Hume's view of necessity remains in place: it is just that the world, while being allowed to be real enough for everyday concerns, is no more real – no more independent of us – than necessity and possibility.

Hume seems to have to think that modal conclusions can only be based on reasoning concerning "abstract relations of our ideas" (Hume, 1978, p. 413), and ideas, for Hume, are components of thought. Kant, similarly – on the received interpretation I am following – seems to have taken the conception of the world in which modality has its home to be derived from judgment, whose structure and character is then inevitably reflected in the world which we think about. And this gives us reason to give thought a special place in philosophy, in so far as we think that philosophical conclusions are modal. If we follow the Humean view, and restrict the range of modal truths in his way, philosophy can only be about or expressive of thought and conceptual relations, and cannot reveal the nature of the world. If we follow Kant, and hope for a more ambitious metaphysics, we may be able to acquire knowledge of necessary truths about the world through philosophy, but in so far as the truths are necessary, they will reflect something in the structure of thought.

This conception of things is reflected in the key terms Kant used, which were to shape views of the nature of philosophy up until the latter part of the twentieth century. Crucial here are the terms 'analytic' and 'synthetic.' The class of analytic truths coincides roughly with what Hume would count as truths concerning 'abstract relations of our ideas.' And the

class of synthetic truths coincides roughly with truths which can be said to be genuinely revealing of the world. On Kant's account, necessary truths have to be *a priori* (Kant, 1997, B3), so in order to make sense of the possibility of metaphysics, we have to make sense of the possibility of synthetic *a priori* truths (Kant, 1997, A9–10; B13–14). Because he insists that what we need for metaphysics is something which is at least *a priori*, and he understands the *a priori* as what does not depend on sense-experience, Kant is in effect accepting the Humean view of the importance of the division between what does and what does not depend on sense-experience. In effect, he accepts the empiricist view that the world – at least as we can have knowledge of it – will be what we can have sense-experience of. Since Kant takes the *a priori* to be, roughly speaking, what we bring to experience, rather than what we get from it, allowing that there can be synthetic *a priori* truths already seems to commit him to the view that the world as we can know it depends on what we bring to experience.

If we interpret Dummett's conception of philosophy against this background, the importance he gives to the philosophy of language seems ultimately to depend on an antecedent commitment to the importance of metaphysics (or the nearest we can get to it) within philosophy as a whole, even if it goes by way of a form of anti-realism about modality. We can offer the following roughly formulated argument on his behalf:

(1) Metaphysics (or the nearest we can get to it) is the most fundamental philosophy;
(2) Metaphysics (or the nearest we can get to it) is to be pursued through an understanding of thought;
(3) Thought is to be understood through the philosophy of language; *so*
(4) Metaphysics (or the nearest we can get to it) is to be pursued through the philosophy of language; *and*
(5) The philosophy of language is the key to the most fundamental philosophy.

We were struck earlier by the importance Dummett gives to an understanding of thought. That is expressed here in (2), which gives voice to a form of anti-realism about modality. But we can get a similar general view about the importance of the philosophy of language within philosophy as a whole without talking much about thought at all. We get a more direct argument for the same conclusion if we simply omit (2) and (3), taking (5) to follow directly (as it does) from (1) and (4). I suggest that this second, more direct argument expresses a long-standing and still widely prevailing view. This more direct argument is itself, strictly speaking, neutral on the question of realism about modality.[8] It has certainly been understood through the lens of a broadly Humean anti-realism about modality, and I will look first at versions of the view which might seem to depend on that kind of understanding: these were dominant in the English-speaking world in the middle third of the twentieth century. But I will then turn to more recent approaches to philosophy, which also give a central role to the philosophy of language; these can also be understood as adhering to something like the more direct argument of (1), (4), and (5), and they are at least compatible with some form of realism about modality.

3 Wittgenstein, Early and Late

If you adopt a Humean combination of general realism about the world and anti-realism about modality, while thinking of metaphysics as the discovery of necessary truths about the world, you are likely to count metaphysics as being of relatively slight importance. If you

also hold (1), that metaphysics (or the nearest we can get to it) is the most fundamental philosophy, you will count philosophy in general as being of slight importance. This kind of view is associated with Ludwig Wittgenstein, in both his earlier and his later philosophy. And in both cases the approach to philosophy comes with the view that the most fundamental philosophy is to be approached through an understanding of language. I will suggest that although the early philosophy was one of the direct inspirations for a neo-Humean movement in philosophy – known variously as logical empiricism or logical positivism – it is in fact more Kantian than Humean. The later philosophy, however, can be seen as more simply Humean. I will begin with the later work, because this will enable us to understand more clearly how Wittgenstein's work as a whole connects with the Humean tradition.

Here is one of the most simply revealing sequences in Wittgenstein's later philosophy (2009b, 315):

> I can know what someone else is thinking, not what I am thinking.
>
> It is correct to say "I know what you are thinking," and wrong to say "I know what I am thinking."
>
> (A whole cloud of philosophy condenses into a drop of grammar.)

The first sentence here makes a modal claim: it asserts that something is *possible* (knowing what someone else is thinking) and that something else is *impossible* (knowing what one is thinking oneself). This seems to be exactly the kind of modal claim which Hume thought was spurious: it appears to say something about what is possible and what impossible *in the world* (some things really *can* be known, others really *cannot*).[9]

The second sentence then offers a parallel claim about what it is correct or incorrect to *say* – a claim about the rules for the use of the word 'know.' And the third sentence, in effect, claims that the sentence about linguistic rules gives the essence of the apparently modal claim of the first sentence. A way of putting the point here would be to say that what seems to be a modal claim about the world is really no more than an expression of a truth about the rules for using a word. This is naturally understood as a form of *projectivism* about necessity. Projectivism about a given subject-matter is the view that what we take to be real features of the world are in fact just projections of features of our ways of thinking of or representing the world. It gets its classic statement in this sentence of Hume's (where he is asserting a form of projectivism about value) (Hume, 1975, p. 294):

> The one [reason] discovers objects as they really stand in nature, without addition or diminution: the other [taste] has a productive faculty, and gilding or staining all natural objects with the colours, borrowed from internal sentiment, raises in a manner a new creation.[10]

Wittgenstein seems to be saying that what we take to be a necessary truth about the world is really a projection onto the world of an aspect of the rules of our language.[11]

What we have here is something like the classic Humean contrast between realism about the world and anti-realism about modality. In this case, the claim is not that "Upon the whole, necessity is something, that exists in the mind, not in objects," but, in effect, that, upon the whole, necessity is something that exists in linguistic rules, not in objects. And this is not without consequences of its own, of course. What it means is that when someone seems to say something which we might think of as the negation of a necessary truth, it is not that they have said something which is necessarily false, but that they have broken the

rules, and so have really failed to say anything at all: they have just been misusing the words, producing something which is ungrammatical, or nonsense.

What is notable about this view of Wittgenstein's is that there is no detour, as there was in Dummett's case, by way of thought. The source of what seems to us to be necessity in the world is, according to Wittgenstein, nothing but the rules of a particular language; and the key thought here is that these are in a fundamental way arbitrary and historical (Wittgenstein, 2009a, 372). The relevant kind of arbitrariness is just that the rules of a language are not dictated by the way the world is (Wittgenstein, 2009b, 366); so the arbitrariness which Wittgenstein finds in linguistic rules is just another aspect of his anti-realism about necessity – for if linguistic rules had not been arbitrary in this sense, they would have reflected a deeper necessity in the world. Once this is appreciated, there seems an obvious reason to find the source of necessity in language, rather than in thought: the rules of particular languages are more naturally taken to be arbitrary than the rules of thought. If we had taken linguistic rules to be a reflection of the structure of thought, it would have been natural to take them to be determined by the way the world is; it would have been natural to take linguistic rules to be an expression of the necessity of that part of the world which is the way we think.

This fundamentally Humean view of necessity leads naturally to a downgrading of the importance of philosophy, and that is indeed characteristic of the later Wittgenstein. It has recently become common to read a similar attitude to philosophy back into his earlier work,[12] but this is hard to square with some central features of that earlier work. The central claim of the *Tractatus* is that the form of language is the same as the form of the world: in other words, that the ways things can be combined in the world are the same as the ways words can be combined in language. The important thing here is that this is a modal claim: the possibilities for things in the world are the same as the possibilities for elements of language. This immediately makes it impossible to claim that one set of possibilities is less real than the other. The broadly Humean view of the later philosophy, which is naturally characterized as the view that what seems to be necessity in the world is nothing but a projection of the grammar of a language, cannot be made intelligible if the necessity of grammar and the necessity of real combination are the same thing.

In the light of this, people are often tempted to understand the *Tractatus* as a thoroughly realist work: the grammar of language is taken to be a mirror of the form of the world, with the form of the world being imagined to be determinate independently of language (see, e.g., Pears, 1987). Myself, I think this is wrong. Wittgenstein says "what the solipsist *means*, is quite correct" (Wittgenstein, 1922, 5.62), and I see no reason to deny that he is here expressing his own view, even if, strictly speaking, "it cannot be *said*, but it shows itself": in effect, Wittgenstein is a kind of transcendental idealist. It is true that the theory of the *Tractatus* means that nothing can strictly be said about the form of the world – about what is objectively necessary – and the result is that there are almost exactly the same restrictions on the proper range of philosophy as Hume himself would have imposed. But the reason is not, I think – as it seems to have been for Hume – that metaphysical pronouncements are the bogus misrepresentation of features of our system of representation as features of the world, but that what metaphysics would say if it could say anything is too deep in the structure of things to be said. And in any case, there is exactly the same restriction on saying anything about the form of *language* as there is on saying anything about the form of the world – as what I have called the central claim of the *Tractatus* clearly requires. We have a view which looks as if it is Humean, when its spirit is the very opposite of Hume's (see

Carnap, 1963, pp. 25–26). For all that, it does look as if at the heart of the work is an anti-realist view of modality: it is just that – if I am right that Wittgenstein at this point ends up with a form of transcendental idealism – anti-realism about modality leads to a more general anti-realism.

Once again, though – despite Dummett's insistence to the contrary (Dummett, 1978e, p. 442) – there is no detour here through consideration of thought. Thoughts are indeed mentioned (they are introduced at Wittgenstein, 1922, 3, before the official introduction of language at Wittgenstein, 1922, 3.1), but they seem to be kinds of sentence in the mind, rather than the content of sentences (which is what they are for Frege).[13] And at every juncture it is the relation between the world, on the one hand, and *language*, rather than thought, on the other, which is important.[14] Why should this be? It cannot be to support an anti-realist view of necessity by allowing grammar to be arbitrary relative to the world – the view which is to be found in the later philosophy – for in the *Tractatus* neither grammar (here just syntax) nor the form of the world is arbitrary. I suspect that there are two key reasons, both derived ultimately from Frege. First, whatever else it is about, the *Tractatus* is about logic, and the formal representation of logic is one of its chief concerns: this immediately gives an important place to language – or at least to the refined symbolism of the fully analyzed language whose sentences will consist just of names of simple objects. The other reason is the Context Principle. In its loosest forms, this principle says little more than that there is no more to the meaning of a word than its contribution to the meaning of sentences of which it can form part.[15] But Wittgenstein adopts the strictest possible interpretation of it: "only in the context of a proposition [sentence] has a name meaning" (Wittgenstein, 1922, 3.3). The core thought here is that there is something basic about sentences – what distinguishes them from lists – which cannot be captured by thinking of sentences as constructed out of independently intelligible words. It is tempting to think that this inevitably puts language at the center of the picture: sentences simply strike us as units. As for thought and the world, on the other hand, even if we acknowledge counterpart kinds of unit – judgments or thoughts, and facts or states of affairs, respectively – it is only as the counterparts of sentences that they are intelligible as units.

4 Carnap and Quine

Even if it is in fact questionable whether the *Tractatus* is a Humean work, it was certainly taken up in a Humean way – most notably by its most famous philosophical reader, Rudolf Carnap. The striking influence of the *Tractatus* on Carnap is evident if we compare his first book (Carnap, 1967a) with an article published in the same year (Carnap, 1967b). The first version of Carnap (1967a) was written between 1922 and 1925, before Carnap had read the *Tractatus*. Carnap (1967b), however, was written in 1927, after he had read the *Tractatus*. There are two striking differences which are relevant here. First, Carnap (1967a) is not centrally about language: although the book embarks on its project by considering the form of scientific *statements*, and advances further in the same way, what it aims to construct is a system of *concepts* – and hence of their correlative objects – on the basis of a set of fundamental *concepts*. And second, although the book does contain (Carnap, 1967a, §106) the characteristic Humean division between the modal and the world-involving, and with it a rejection of metaphysics as Kant conceives of it, in its main treatment of philosophical issues it is surprisingly permissive, merely insisting that they belong to metaphysics and not to science. Carnap (1967b), however, is much more aggressive. Carnap's dismissal of

metaphysics here does not overtly depend on Hume's Fork, but it does depend on a verificationist criterion of 'factual content' for counting any statement meaningful.[16] And the centrality of that meaning criterion also puts language at the heart of things.

Things are both more explicit and more direct in Carnap (1959), first published just four years later. Here we get an almost explicit restatement of Hume's Fork (Carnap, 1959, p. 77):

> (Meaningful) statements can be divided into the following kinds. First there are statements which are true solely by virtue of their form ("tautologies" according to Wittgenstein; they correspond approximately to Kant's "analytic judgments"). They say nothing about reality … Secondly there are the negations of such statements ("*contradictions*"). They are self-contradictory, hence false by virtue of their form. With respect to all other statements the decision about truth or falsehood lies in the protocol sentences. They are therefore (true or false) *empirical statements* and belong to the realm of empirical science.

And this is applied to dismiss any kind of philosophical statement one might imagine: all that is left of philosophy is a certain method, rather than any body of knowledge. What we have here is the result of a Humean view of necessity, reshaped in line with a Humean reading of the *Tractatus*, to make the crucial relation one between language and the world, rather than between the mind and the world.

This general linguistic reorientation of Humeanism continues into Carnap's mature philosophy, though with an interesting twist. In his (1956a), Carnap introduces the idea of *linguistic structures*, which become *linguistic frameworks* in the more thorough treatment of these issues in his (1956b). A linguistic framework is a language (or part of a language) together with a semantic interpretation of it which determines, among other things, which entities are correlated with its terms.[17] Given the idea of a linguistic framework, Carnap is able to distinguish between what he calls *internal* and *external* questions. Internal questions are questions raised within a linguistic framework, and to these a version of Hume's Fork applies. The semantic rules of the framework determine first that some sentences will be *L-true* – true in the framework "in such a way that [their] truth can be established on the basis of the system … alone, without any reference to (extra-linguistic) facts" (Carnap, 1956a, p. 10) – second, that some sentences will be *L-false* – those whose negations are L-true – and third, for the rest, which empirical circumstances would be involved in their being true. The sentences which are L-true within the system are meant to be those which Kant would have counted as analytic; all other truths are synthetic. External questions, by contrast, are questions about whether to adopt some particular linguistic framework. To this class Carnap consigns questions of ontology, in so far as they are both significant and intelligible. External questions are essentially practical questions in Carnap's view (Carnap, 1956a, p. 43): questions about which framework works best for a given purpose. He thinks of the problems involved here as, in a sense, 'engineering problems' (Carnap, 1956a, p. 43). And he does not assume that the same framework will be appropriate for every purpose (1956a, p. 43; 1956b, p. 208). The important point here is that the question whether to accept a particular linguistic framework *replaces* the question whether the entities referred to by the framework's basic terms really exist: it is not the *same* question. The question whether the entities referred to by a framework's basic terms *really* exist is still regarded – just as it was in Carnap (1967b) – as a pseudo-question (Carnap, 1956b, pp. 214–215). There is no issue of truth for a framework, or of the correctness of accepting it, beyond the question whether the framework is practically useful for a given purpose.

Carnap's general view of philosophy forms the background, and to some extent the target, of the work of W. Van Orman Quine. It is a delicate question exactly what kind of challenge to Carnap's picture is provided by Quine's most famously revolutionary essay, "Two dogmas of empiricism" (Quine, 1953). We can pick out two parts of this essay which are particularly significant for our purposes. First, Quine attacks the notion of analyticity, arguing that it can be given no proper explanation and that its application is unclear. Second, Quine proposes an alternative picture, in which analyticity apparently has no place. The simplest way of understanding what is novel about the new picture is this. First, where Carnap insists on a firm distinction between two kinds of question – internal questions, which operate within the semantic rules of a given framework, and external questions, which concern the choice of framework – Quine makes no such distinction: we have, on the one hand, a single "field of force" which contains "[t]he totality of our so-called knowledge or beliefs, from the most casual matters of geography and history to the profoundest laws of atomic physics or even of pure mathematics and logic" (Quine, 1953, p. 42), and on the other hand, experience, which may or may not be recalcitrant; any part of the former may be adjusted to deal with a failure of fit with the latter. Second, where Carnap insists on a firm distinction (within each framework) between those truths which are analytic and those which are not, Quine characterizes analytic truths as those which "hold come what may," and then insists that there is no absolute distinction between those statements which can be held true come what may and those which cannot: "[a]ny statement can be held true come what may, if we make drastic enough adjustments elsewhere in the system"; and "[c]onversely, by the same token, no statement is immune to revision" (Quine, 1953, p. 43).

These ways in which Quine differs from Carnap seem to complicate the relationship between language and philosophy – and indeed between philosophy and other disciplines. Whereas for Carnap there is a relatively clear and separable task for philosophy in the working out of the semantics of linguistic frameworks, and in the higher-order questions of what is involved in that working out, on Quine's account there seems to be no way of separating those questions from other, more obviously scientific, questions, and correspondingly no clear and separable role for philosophy: it is just that the philosopher works in the part of the 'field of force' constituted by the totality of our beliefs which is relatively close to its more theoretical 'core,' at some distance away from the 'periphery' where experience is actually encountered; the philosopher seems to become a kind of theoretical scientist. The abandonment of Hume's Fork in the rejection of the distinction between analytic and synthetic truths seems to bring with it an abandonment of the idea that there is a special relationship between philosophy and language.

That, at least, is how things seem, on the face of it. In fact, however, although there is indeed a radical divergence, it is not clear that it has quite the form which Quine suggests. First, Quine himself seems clearly to endorse a form of linguistic Humeanism in his (only slightly later) treatment of necessity. In (Quine, 1966) Quine attempts to demonstrate that the idea of *de re* modality – of necessities and possibilities arising from the nature of things – is incoherent. But he does not reject necessity altogether, and he clearly identifies the idea of *de re* modality with a pre-Humean – more specifically, Aristotelian – conception of necessity. He thinks we need some notion of necessity to characterize implication, and we need the notion of implication to characterize the notion of validity which we need for proof theory. Much of the technical part of (Quine, 1966) is devoted to the preliminary work of providing the semantics for a notion of necessity which will do this work without bringing in a pre-Humean idea of modality. The idea is to characterize a predicate of

necessity which will apply to whole sentences, without introducing any modality which applies to objects in virtue of their natures. Quine puts the point like this:

> Necessity as a semantical predicate reflects a non-Aristotelian view of necessity: necessity resides in the way in which we say things, and not in the things we talk about. (Quine, 1966, p. 176)

This looks like an echo of Hume (1978, p. 165); it seems inevitably to reintroduce Hume's Fork, and with it some (possibly restricted) notion of analyticity.

A little thought suggests that there is nothing here which is fundamentally incompatible with the holistic 'field of force' picture with which Quine aims to replace Carnap's conception of questions which are internal and external to linguistic frameworks – at least if we correct what looks like a mistake in Quine's presentation. I noted before that Quine characterizes analytic truths as those which "hold come what may," and that he goes on to reject the analytic–synthetic distinction by claiming that "[a]ny statement can be held true come what may, if we make drastic enough adjustments elsewhere in the system." There is an obvious slide here, even if it may seem a more natural slip for an anti-realist about modality to make. The things which 'hold come what may' are the analytic truths themselves (if there are any): to say that they hold come what may is to say that they are true no matter what – in other words, one would think, that they are necessarily true. This is a remark about statements and their status – not a remark about us. But when we say that "any statement can be held true come what may," it is we ourselves who do the holding: the claim Quine is making here is that we can rationally accept or reject any statement at all, provided we make suitable compensations elsewhere. This is a remark about us, and says nothing about the modal status of any statement: in particular, it does nothing to suggest that there are no truths which hold come what may. What this means is that Quine's holistic vision of the totality of our beliefs forming a single 'field of force' is in fact compatible with acknowledging that some truths are necessary and some are not. And, as we have seen, it is at least Quine's only slightly later view that we have to accept this if we are to make sense of implication and validity.

If we incorporate this point, what difference does it make to Quine's view, and in particular to the difference there appeared to be between his view and Carnap's? First, among the beliefs which form Quine's 'field of force,' there may be some beliefs that certain statements are necessary. We have seen that Quine seems later to be committed to allowing this, in order to make sense of implication. And there seems good reason to think that he will need there to be some such beliefs, if he is to make sense of there being any confrontation between the totality of our beliefs and experience. For if our beliefs have no implications, it is hard to see how any experience could be recalcitrant, and so force revision, or how any experience could confirm our beliefs, and so encourage us to leave things unrevised.

This has no tendency to undermine the holism of Quine's general picture, or to suggest that these beliefs about what is necessary will be held true come what may: we can continue to hold that "no statement is immune to revision" – and this will include statements to the effect that this or that other statement is necessary. This suggests that how wide the class of necessary truths is is something which cannot rationally be determined once and for all, in advance of general scientific enquiry: in particular, we cannot rationally restrict it to what we might think of as narrowly logical truths, or to any particular wider class of analytic truths.

What does change, however, is the place and role of philosophy. If the totality of our beliefs "face the tribunal of sense experience not individually but as a corporate body" (Quine, 1953, p. 41), and "no statement is immune to revision," it looks as if the decision to revise a belief about the necessity of some statement – in effect, for Quine, a belief about what implies what – is one that could in principle be made by a scientist, rather than a philosopher. If that is right, the central moral which is to be drawn from the revolutionary new picture of the essay is not anything in particular about analyticity, but a form of the general view with which Quine was later to be associated – what is known as his *naturalism*. The key move here is the "abandonment of the goal of first philosophy" (Quine, 1981, p. 72); he ends up with a view that sees philosophy "not as an *a priori* propaedeutic or groundwork for science, but as continuous with science" (Quine, 1969, p. 126). These remarks seem if anything to understate the change Quine envisages. It is not just that there is no *first* philosophy, on Quine's picture – rather, it seems that there is no distinctive role for philosophy, as we ordinarily envisage it, at all: there is nothing more than very theoretical science.

For all that, in his actual practice Quine seems to have continued very much as Carnap might have (making allowances for other differences between them). His work continues to be focused centrally on the analysis of language and on semantic proposals for linguistic constructions of various kinds. It is no accident that the great monograph of his mature years is called *Word and Object* (Quine, 1960). And in this language-centered work, there is little sense that the semantic claims which are made take into account the latest developments of empirical science.

5 Ordinary Language Philosophy

We have seen that the special place given to the philosophy of language in the logical positivist tradition arises naturally from that tradition's broadly Humean anti-realism about modality. But what are we to make of the anti-theoretical, anti-systematic movement which grew up a little later, known rather loosely for practicing 'ordinary language philosophy'? This movement might seem to place language at the center of philosophy even more obviously than Carnap and Quine, for example, do, but it characteristically avoids the grand methodological visions and manifesto declarations of a Carnap or a Quine; we will not easily find any clear commitment to Hume's Fork here. I will argue that the ordinary language tradition had its *origins*, at least, in anti-realism about modality, and continued throughout its history to take an attitude to philosophy in general, and metaphysics in particular, which is hard to justify without that anti-realism – even if it is characteristic of the philosophers in this tradition that they did not generally attempt to justify it.

The ordinary language tradition is often associated with the work of the later Wittgenstein,[18] and it is in that association that a form of it continues to this day. But it seems more plausible to suggest that its origins lie rather in Wittgenstein's *earlier* philosophy. If anything deserves to be counted as the founding text of ordinary language philosophy, it is Gilbert Ryle's "Systematically misleading expressions" (Ryle, 1932). What Ryle wants to argue for is this claim (Ryle, 1932, pp. 142–143):

> There are many expressions which occur in non-philosophical discourse which … are … couched in grammatical or syntactical forms which are in a demonstrable way *improper* to the states of affairs which they record.

This gives philosophy a task, which Ryle himself is inclined to believe is "the sole and whole function of philosophy" (Ryle, 1932, p. 170): to reformulate the misleading expressions to ensure that "the syntactical form is proper to the facts recorded" (Ryle, 1932, pp. 142–143).

Although Ryle himself disagrees with one important feature of (Wittgenstein, 1922), it seems clear that in identifying "systematically misleading expressions" and reformulating them to avoid what is misleading about them, he is doing just what Wittgenstein seems to be recommending in that work. Ryle identifies the point of disagreement as the view that "what makes an expression formally proper to a fact is some real and non-conventional one–one picturing relation between the composition of the expression and that of the fact" (Ryle, 1932, p. 167), but some notion of "propriety of grammatical to logical forms" there apparently has to be: it is just that at this point Ryle takes it to be "more nearly conventional than natural" (Ryle, 1932, p. 168).

The role given to philosophy by Ryle seems precisely the one assigned to it by Wittgenstein (Wittgenstein, 1922, 4.112): "The object of philosophy is the logical clarification of thoughts." And what this means is made clear by an earlier remark, approving of Russell (Wittgenstein, 1922, 4.0031):

> All philosophy is "Critique of language" (but not at all in Mauthner's sense). Russell's merit is to have shown that the apparent logical form of the proposition need not be its real form.[19]

In (Ryle, 1932), Ryle offers no reason for his view that this clarification of syntax is "the sole and whole function of philosophy." But there is a hint in a later paper – also largely concerned with philosophical methodology – of what lies in the background (Ryle, 1937). Considering the kind of principles which define a school of philosophy, he asks how they are to be established, and it is clear from the reference to Hume and Kant in his answer (Ryle, 1937, p. 325) that he takes Hume's Fork to provide a significant challenge to any account; and as we saw, the problem there derives from anti-realism about modality.

I said that (Ryle, 1932) has a good claim to be the founding text of ordinary language philosophy – the movement in philosophy in which language most obviously takes the center of the stage. There is one way in which it is uncharacteristic of the movement as a whole: at the time he wrote it Ryle says that he was still under the influence of the doctrine "according to which there were a certain number of logical forms which one could somehow dig up by scratching away at the earth which covered them" (Rorty, 1967, p. 305). This doctrine he later abandoned. But in all other respects, it seems to me, the work is broadly representative of the whole movement. We might note the following key points in particular:

(i) It holds that it is at least a central task of philosophy to remove confusions which arise from misunderstanding ordinary language;
(ii) It takes philosophers to be subject to these confusions, while ordinary people are not;
(iii) It is generally pessimistic about the possibility of substantial or systematic philosophy (metaphysics, for example), without offering any principled justification for this pessimism.

These features undergo a slight transformation in the work of J. L. Austin, the other obvious pillar of the ordinary language movement.[20] He is concerned to remove confusions

which arise from misunderstanding ordinary language, but his more central concern is to look attentively, with an almost literary eye, at distinctions which are made in ordinary language, the careful observing of which he thinks will prevent us falling into the kinds of confusion to which philosophers are prone.[21] This seems to me to be broadly continuous with Ryle's concern in (Ryle, 1932), even if its focus tends to be on particular words, rather than on constructions.[22]

Feature (iii) seems to me to be particularly characteristic of the ordinary language movement. The lack of principled justification for the pessimism about substantial or systematic philosophy might seem to undermine my suggestion that the linguistic turn is motivated by a roughly Humean view about necessity, given a linguistic cast by Wittgenstein's early work. But the fact that Ryle's approach has its roots in (Wittgenstein, 1922), and that he was clearly sensitive to Hume's challenge to metaphysics, provides at least genealogical support for my suggestion:[23] the movement's character is still broadly Humean, even if its members were not all Humean in their conscious allegiances. (And in fact I suspect that some form of Humeanism was at least the closet orthodoxy of the age.[24])

The relation of the later Wittgenstein to this school seems to me complicated, despite the fact that he is often associated with it. The later Wittgenstein engages with issues in metaphysics more explicitly than those most obviously within the ordinary language movement – particularly in connection with mathematics. And I have already argued that he is naturally read as a Humean about necessity. But he can be made to seem closer to ordinary language philosophy by concentrating in particular – and often out of context – on those parts of his later texts which seem to exemplify features (i), (ii), and (iii). (See, for example, Wittgenstein, 2009a, 116, 124, 128, 133.)

In a similar way, the early Wittgenstein can be brought broadly within the ordinary language movement by picking out those parts of (Wittgenstein, 1922) which I earlier suggested as an inspiration for Ryle – while ignoring their rationale in a particular metaphysics of modality. (The recent 'new' or 'resolute' reading of (Wittgenstein, 1922) seems to me to do exactly this. See, e.g., Diamond, 1991, and Conant, 2000.) In the case of the early Wittgenstein, this seems to me to lead to a misinterpretation;[25] in the case of the later work, to an oversimplification, at the very least.

6 The Turn Back

I have suggested that the linguistic turn, in all its various manifestations, depends on a general anti-realism about modality, which takes a linguistic form as a result of the early Wittgenstein's concern with formal logic and his commitment to the importance of the Context Principle. Philosophy has moved on from the linguistic turn in its classical forms, however – at least in the English-speaking world: metaphysics is now pursued unapologetically, and central debates in metaphysics have a place in contemporary philosophy not unlike the place occupied by the various manifestations of the linguistic turn in their heyday. If I am right about the basis of the linguistic turn, we should expect the turn back to depend on a rejection of anti-realism about modality.

And so indeed it seems. It is natural to trace the beginning of the gradual rejection of the linguistic turn to the work of Ruth Barcan Marcus, who set about patiently unpicking Quine's arguments against *de re* necessity – his arguments for his version of Hume's Fork.[26] Marcus's work was taken up, developed, transformed, and made readily accessible even to

philosophers with no great technical expertise, by a younger ally in her exchanges with Quine, Saul Kripke.[27] Developing a larger philosophy from Marcus's important thought that names are just tags while descriptions are not, pressing further Marcus's sensitivity to the possibility that different contexts might impose different constraints on substitution, and building on his own earlier work on the semantics of modal logic, Kripke challenged the assumptions on which anti-realism about modality depends, and made the idea of metaphysics respectable again. He insisted on a crucial difference between the notions of the *a priori* and the necessary. The former deals with an issue about how things are known: it is, as Kripke says, "a concept of epistemology" (Kripke, 1980, p. 34). The concept of necessity, on the other hand, "is not a notion of epistemology, but of metaphysics, in some (I hope) non-pejorative sense" (Kripke, 1980, pp. 35–36). This apparently simple point transformed philosophy. There may have been an argument back in the history of philosophy for assimilating the *a priori* and the necessary – perhaps the combination of Hume's empiricism with his theory of perception provides one – but from now on some argument had to be provided: the two concepts could not just be assumed to coincide. As for the concept of analyticity – once the notions of the *a priori* and the necessary have been distinguished, it no longer seems to have such central importance: Kripke simply stipulates that what is analytic is both necessary and *a priori* (Kripke, 1980, p. 39).

Kripke also provides a direct, informal attack on the Humean approach to modality, by showing, with a range of simple examples, how natural and unproblematic in everyday life *de re* modality is.[28] He even turns the ordinary language movement's suspicion of philosophy back against it (Kripke, 1980, p. 41):

> Suppose that someone said, pointing to Nixon, 'That's the guy who might have lost.' Someone else says 'Oh no, if you describe him as "Nixon," then he might have lost; but, of course, describing him as the winner, then it is not true that he might have lost.' Now which one is being the philosopher, here, the unintuitive man?

If Kripke made metaphysics respectable for the majority of philosophers, whether or not their interests lay in formal logic, it is his contemporary, David Lewis, who provides the clearest model of what a modern metaphysics might be like. Lewis's work ranges across many fields – wherever he found a philosophical puzzle, he seems to have offered a novel solution to it – but at its core is his approach to modality, and the distinctive way in which he defends his modal metaphysics. The key to Lewis's conception of modality is his understanding of possible worlds. Possible worlds have a significant history in analytic philosophy: the notion can be traced back to Carnap's notion of 'state descriptions,' which he uses to define the notion of L-truth (Carnap, 1956a, p. 9), and beyond him to Wittgenstein's notion of a 'possible state of affairs' (Wittgenstein, 1922, 4.462).[29] A real transformation occurred, however, in the late 1950s and early 1960s: to simplify hugely, the equivalences between "*s* is necessarily true" and "*s* is true in every possible world," on the one hand, and "*s* is possibly true" and "*s* is true in some possible world," on the other, were exploited to enable the familiar semantics for ordinary predicate logic to be used to generate semantics for modal logic (see in particular Kripke, 1959; 1963a; 1963b).

Lewis's view of modality can be characterized by means of four key commitments (though these are not always clearly separated). First, he is a *realist* about modality: that is, he is committed to the view that claims about what is necessary and what is possible can be strictly true and strictly false, and their truth and falsity is not dependent on facts about

thought or language.[30] Second, he is what may be termed a *literalist* about semantics: he seems to accept the view that it is in principle possible for a semantic theory for a language (or for some part of a language) to be literally true, and if that semantic theory implies a given claim, then that claim is literally true. For our case, if the true semantic theory for modal language (as well, perhaps, as propositional-attitude constructions and talk of properties) implies that there are possible worlds, then there literally are such things as possible worlds. Since Lewis holds that the true semantic theory does indeed involve the claim that there are possible worlds, and he is also a realist about modality, he is committed to the view that possible worlds really exist, independently of facts about thought or language. Third, he is a *reductionist* about modality: that is, he thinks modality – necessity and possibility – needs to be defined in more fundamental terms (Lewis, 1973, p. 85). In particular, he thinks that facts about necessity and possibility are reducible to facts about possible worlds: the facts about possible worlds are fundamental, and can be used to explain necessity and possibility. And fourth, Lewis is a *concretist* about possible worlds: that is, he thinks possible worlds are themselves concrete individuals, spatio-temporal entities "something like remote planets" (Lewis, 1986, p. 2).

These last two commitments are the most contentious features of Lewis's approach to modality. Lewis initially describes possible worlds as "ways things could have been" (Lewis, 1973, p. 84), but it is quite unclear that ways things could have been are concrete individuals (see Stalnaker, 1976). And if we try to reduce necessity and possibility to facts about possible worlds, there is at least some work to be done to explain how the nature of a *possible* world is independently intelligible – intelligible, that is, independently of necessity and possibility.

On the other hand, the first two of the four commitments of Lewis's view which I have identified seem to me to be central to the mainstream of metaphysics after the linguistic turn. I will deal briefly here with the first one – realism about modality – before turning to the second – literalism about semantics – in the next section. I have suggested that it was anti-realism about modality which lay at the root of the linguistic turn which dominated English-speaking philosophy in the middle third of the twentieth century, and which was broadly hostile to metaphysics. I think it is clear that it was the questioning of that anti-realism which opened the way back from the linguistic turn. Not every modern metaphysician need be a realist about modality, even if many indeed are: they might be anti-realist, or they might not be concerned with modality in particular. But the challenge to the anti-realist orthodoxy has meant that people can be metaphysicians again, in ways that reach back to work which was done before the linguistic turn. I began with the strikingly contrasting views of Dummett and Williamson on how philosophy ought to be done. It is no accident that Williamson, after a series of negative arguments against the general conception of philosophy which Dummett might be taken to represent, begins the positive task of sketching an alternative view by presenting the outline of an epistemology of modality (Williamson, 2007, ch. 5). I have suggested that the source of the language-oriented hostility to metaphysics which characterizes the linguistic turn lies in a form of Humeanism about necessity. That Humean view in turn depends on a certain epistemology: empiricism as a general theory of how we can have knowledge of what is independent of us, combined with a particular theory of perception. Overturning the Humean view must involve producing an alternative epistemology of modality, which is exactly what Williamson does.

7 The Larger Picture

Despite the fact that Lewis represents a rejection of the linguistic turn, language is still of fundamental importance to his philosophy. This is because of the semantic literalism which he shares with the mainstream of contemporary metaphysics.[31] I want now to raise some questions about this semantic literalism. The position which contemporary metaphysicians commonly end up with depends on the thought that the best semantic theory for our languages and our logical systems reveals the ultimate nature of reality. This does not in itself mean that semantics should or can be pursued independently of other considerations in order then to reveal the nature of reality, without further adaptation. There need be no bar, in principle, to other, non-linguistic considerations being brought to bear on our choice of semantic theory. Nor, therefore, does semantic literalism *have* to take semantics, or the philosophy of language more generally, to be prior to metaphysics – even if semantic literalists may often be tempted to do so.[32] Of course, since semantics is naturally understood as connecting language with the world, we may anyway think that semantics and metaphysics need to be done together; but the semantic literalist need not then suppose that there is at least something about language which we can get at independently of metaphysics, which decisively determines the truth in metaphysics. Semantic literalism does not, therefore, have to take syntax, for example, to be both prior to and determinative of ontology.[33] Semantic literalism is just the view that we should end up with a semantic theory which connects language and logic, on the one hand, with the fundamental nature of reality, on the other, and that, if we get things right, what such a theory is committed to reveals the literal truth about reality.[34] What this means is that the semantic literalist can be understood as accepting a form of the key assumption of the argument we derived from Dummett at the end of §2:

(4) Metaphysics (or the nearest we can get to it) is to be pursued through the philosophy of language.

It is true that (4) is naturally read as suggesting that we can do the philosophy of language in some way in advance of doing metaphysics, and then derive the metaphysics from it; but it can also be read more neutrally, as suggesting that metaphysics and the philosophy of language must be worked out together.

Semantic literalism applies at different levels, from the more specific to the very general. At the more specific level, we might find, for example, the semantics of claims of the form '*a* knows how to φ' being taken to reveal the true nature of practical knowledge (see, e.g., Stanley and Williamson, 2001, and Stanley, 2011). But it is at the more general level that the issues are most striking. We have seen the suggestion that the best semantic theory for modality shows that there really are possible worlds; but there are more familiar, more apparently venerable examples. The ancient idea that reality contains a fundamental distinction between substance and attribute[35] – or, in its more modern guise, between object and property or relation – seems to imply that the best semantic theory correlates different kinds of entity with singular terms, on the one hand, and predicates, on the other. And another ancient thought, that we should ideally 'carve reality at its joints,'[36] requires reality in itself to have joints; and that in turn seems to need reality itself to be already divided into the classes demarcated by the most fundamental predicates.

There are a number of worries about semantic literalism – though the issues are too large to pursue in any detail here. One reason for worrying about semantic literalism is that

semantic theories are characteristically answerable to considerations which seem not to have much to do with the description of reality. One significant advantage of possible worlds semantics for modality, for example, is that it enables us to use the relatively familiar resources of the semantics of classical predicate logic to derive metalogical results for modal logic. And again, one of the attractions of classical logic itself is the smoothness of the derivation of metalogical results for it. It is not obvious why we should think that these benefits have much to do with the description of the ultimate nature of reality – unless we are either anti-realists, thinking that reality itself is nothing more than a projection of our favored theories, or quite optimistic about the way things are shaped independently of us.

It may be replied to this that similar considerations – of simplicity, for example, or smoothness of application – play an important role in our choice of scientific theories. One response to that comparison might then be to suggest that scientific theories are not themselves concerned just with the description of reality (see, e.g., van Fraasen, 1980). But in fact, there seems to be an important asymmetry between scientific and semantic theories. We expect a scientific theory of some phenomenon to include an account of the relation between the fundamental entities and features posited by the theory, on the one hand, and the phenomenon itself, on the other. But no such thing is generally provided with any seriousness in semantic theories.

At base, semantic theories characteristically *assign* entities or classes of entities to expressions in the language or system in question, and the behavior of the expressions on that assignment is compared with the way the expressions antecedently seem to behave. Deviations between the behavior of the expressions on the relevant assignment and the behavior they antecedently seem to have can be explained in a number of ways. In an ideal case, we might hope to explain all such deviations *away*. What this would leave us with is something like this claim: these expressions behave as they *would* if these assignments *had* been made – it is *as if* these assignments had been made.

Semantic literalism demands something more than this, however: it wants to be able to claim that these assignments have *in fact* been made – the expressions behave like this because these entities or classes of entities *have been* assigned to them. The key move will be a form of inference to the best explanation: the reason why it is *as if* these assignments have been made is because these assignments have *in fact* been made. The difficulty here, however, is that there is seldom much of a story about how the relevant assignments were made. Sometimes there might seem to be a merely local difficulty: a particular semantics-cum-metaphysics might leave us with a puzzling epistemology. (Some of the natural disquiet about Lewis's particular form of realism about possible worlds may perhaps be traced to this.) But there may be a difficulty of principle. If we think that the assignments made by a semantic theory are the same as the assignments which have in fact been made, in some way, in the determination of the meaning of the expressions of a language, it looks as if we need to think of reality as having something which is somehow like the structure which the semantic theory takes the language to have. One difficulty with this is that it is not clear that we can make any significant sense of reality, as it is independently of any relation to language, having structure of the relevant kind. If this kind of difficulty cannot be dealt with, there is a problem with the inference to the best explanation which semantic literalism needs to appeal to: the problem is that the supposed best explanation is no explanation at all. The issue here is exactly analogous to one which arises for a certain form of the argument from design for the existence of God. The relevant form of the argument from design claims that the best explanation of the world being *as if* it had been designed is that it was *in fact* designed. The problem is that we have no idea at all of what the designing

could have been, or what kind of mechanism could have been involved in the execution of the design: with these gaps in the story, it cannot be that the existence of God provides the best explanation of the appearances, because it provides no real explanation at all.

I do not claim that this is a decisive objection to semantic literalism: merely that there is a problem which needs to be addressed. And it is not as if semantic literalism is the only possible approach to semantics. After all, it is already a significant empirical fact about a language that its expressions behave *as if* a certain assignment had been made. It is also a significant empirical fact about a language that its expressions behave in some ways *as if* one kind of assignment had been made, and in some ways *as if* a different kind of assignment had been made. We could here choose to follow Carnap in being tolerant of different semantic theories, each with its own advantages for particular purposes. If we think there are difficulties of principle in accepting semantic literalism, this will not seem like a failure to follow the project of semantics through to its proper conclusion.[37] And we can think there are difficulties with semantic literalism without thinking, as Carnap himself of course did, that metaphysical questions are always pseudo-questions. There may be a proper and significant field of metaphysics, without its being inevitably confined by the framework of semantics.

This clearly makes a difference to the place of the philosophy of language within philosophy as a whole. If we accept semantic literalism, a part of philosophy of language – semantics – remains crucial to metaphysics: even if non-linguistic considerations are taken to constrain what semantic theories we take to be acceptable, metaphysics will always be shaped by the project of providing a semantic theory. If we do not accept semantic literalism, on the other hand, the philosophy of language will not have anything like the same importance, even to metaphysics. (We might think that the philosophy of painting, for example, or the philosophy of music, might be similarly important in giving us a sense of the true nature of reality.)

And of course there is another assumption, which I noted right at the outset, but which has not yet been subjected to any serious examination. It is commonly assumed that metaphysics, in so far as it is intelligible at all, is central and fundamental to philosophy. This was the other key assumption ((1)) of the argument we derived from Dummett. The commonly prevailing general sense of the importance of the philosophy of language for philosophy as a whole seems to derive, because of this assumption, from its relation to metaphysics – either as the key to metaphysics, or as what has to be done in place of metaphysics. But in a more inclusive age, this assumption might also be questioned, and branches of philosophy for which metaphysics seems to have only marginal importance might be given equal respect. In that case too, we might take language to be of constant interest – but perhaps of no more importance than other, quite different forms of representation.

Notes

1 The term appears to originate in Bergmann (1967), though it was made famous by Rorty (1967).

2 For those among whom Williamson is naturally placed: Williamson himself mentions Saul Kripke, David Lewis, Kit Fine, Peter van Inwagen, and David Armstrong (Williamson, 2007, p. 19).

3 This suggestion was made to me in conversation by Barry Smith.

4 It is beyond the scope of a footnote to make this claim out in detail: for sketchy support for it I note the apparently verificationist conception of character found early on in Dummett (1978c, pp. 15–16), and the Humean approach to causation in Dummett (1978b). It is also clear that Dummett took the later work of Wittgenstein very seriously – see, e.g., Dummett (1978d, p. 436): the significance of that will appear shortly.

5 The suggestion that this is the ultimate source of Dummett's outlook was made in conversation by Michael Rosen. I here adopt a fairly traditional reading of Hume.

6 The reason for the caveat is the general anti-realism which seems to follow from other things Hume says (Hume, 1978, pp. 66–68): that is, Hume is at least more realist about the world than he is about, say, value (or necessity). But I will not complicate the issue in the main text.

7 For the classic statement see Hume (1975, pp. 163–165), though there is an earlier version in Hume (1978, pp. 413–414).

8 I understand realism about modality, here and throughout, as realism about necessity and possibility, rather than as the specific form of realism about possible worlds which is associated with David Lewis – though I will mention that specific view below.

9 We might note in passing, against those who think that Wittgenstein only ever wanted to say what everyone would agree with, that this modal claim coincides with his own philosophy, but conflicts with what almost everyone regards as common sense, as Wittgenstein himself was clearly aware (Wittgenstein, 2009a, 246).

10 We see Wittgenstein himself adopting a form of projectivism about clear and strict rules of syntax in Wittgenstein (2009a, 104): "One predicates of the thing what lies in the mode of representation."

11 There is an issue whether the resultant view should be counted as an 'error' theory (like the view of ethics to be found in Mackie, 1977, ch. 1) or not. On an error-theoretic account, claims like 'I can know what someone else is thinking, not what I am thinking' would either assert or presuppose that they concerned some necessity which is in the world independently of language; in that case, if projectivism is true, all such claims would be either false or lacking in truth-value. My own feeling is that Wittgenstein is better understood as thinking that there is nothing wrong with the claims themselves – the error belongs just to philosophers, who simplistically understand these claims on the model of other claims, which are really quite different. Whether this makes Wittgenstein precisely a 'quasi-realist,' in the sense of Blackburn (1984) is another matter. (As Blackburn conceives of the position, 'quasi-realism' is concerned not just to assert a projectivist view without accepting an error theory: it aims to explain and justify the realistic appearance of the language; Blackburn 1984, pp. 171, 180.)

12 This is the so-called 'new' or 'resolute' reading of the *Tractatus*: see, e.g., Diamond (1991) and Conant (2000).

13 To see this point, we need to see that when Wittgenstein first introduces the idea of representing the world for ourselves, he uses the colloquial German "Wir machen uns Bilder der Tatsachen" (1922, 2.1), which might ordinarily be translated "We picture facts to ourselves" (as Pears and McGuinness do; Wittgenstein, 1961, 2.1), but he understands it fully literally, as 'We make to ourselves pictures of facts' (as Ogden has it; Wittgenstein 1922, 2.1). (That he understands it fully literally can be seen from a remark he makes about the parallel passage at Wittgenstein, 1922, 3.001, in a letter to Ogden; Wittgenstein, 1973, p. 24.) And then at Wittgenstein (1922, 3) he says, "The logical picture of the facts is the thought," which makes clear that a thought, like a sentence, is a picture – rather than the content of a picture. Again, at Wittgenstein (1922, 4) he writes, "The thought is the significant proposition [*Satz*: I would generally translate this *sentence* in this text]." And in response to Bertrand Russell's request for illumination about Wittgenstein (1922, 3) – "what are its [the thought's] constituents and components, and what is their relation to those of the pictured Tatsache [fact]?" (Wittgenstein, 1995, p. 121) – Wittgenstein says, "I don't know *what* the constituents of a thought are but I know *that* it must have such constituents which correspond to the words of Language. Again the kind of relation of the constituents of thought and of the pictured fact is irrelevant. It would be a matter of psychology to find out" (Wittgenstein, 1995, p. 125). The fact that this is supposed to be the business of *psychology* makes it clear that thoughts here are mental entities of some kind, rather than the contents of anything mental. Further, in response to Russell's question about Wittgenstein (1922, 4) – "Does a Gedanke [thought] consist of words?" (Wittgenstein, 1995, p. 122) – Wittgenstein says, "No! But of psychical

constituents that have the same sort of relation to reality as words. What those constituents are I don't know" (Wittgenstein, 1995, p. 125).

14 Wittgenstein (1922, 5.62) provides an obvious example.

15 Frege himself gives two slightly different formulations (Frege, 1953, pp. x, 73).

16 Carnap himself attributes the view that "metaphysical sentences are meaningless since they are in principle unverifiable" to Wittgenstein (Carnap, 1967a, p. xi).

17 This is clear from Carnap's discussion in his (1956a, pp. 43–44).

18 See the diagram in Hacker (2013, p. 947), and, with a qualification noted in fn. 23 below, Urmson (1967, p. 297).

19 It is surely no accident that two of Ryle's three classes of "sytematically misleading expressions" are found to be misleading in ways that Russell had earlier anticipated (Russell, 1905). Ryle's language, however, is closer to Wittgenstein's than to Russell's, and Russell did not think philosophy was just 'critique of language.'

20 I am reluctant to include P. F. Strawson here, because he is more nearly a Kantian – more nearly a metaphysician. It is true that the metaphysics is said to be merely "descriptive" (Strawson, 1959, pp. 9–12), but I think this undersells what he actually does.

21 Almost all of Austin's works provide examples of this: Austin (1979) is perhaps the most self-conscious methodologically; and Austin (1962) applies the method most clearly to present a sustained attack on a particular philosophy.

22 Urmson (1967) distinguishes what he calls "Oxford analysis" – by which he seems to mean *Austinian analysis* – more sharply from Rylean or Wittgensteinian analysis than I do.

23 In the sense of Nietzsche (1994).

24 Note, e.g., that in claiming Strawson's "descriptive metaphysics" (Strawson, 1959, pp. 9–12) for the ordinary language movement, Hacker says, "descriptive metaphysics is just more analytic description of the structure of our conceptual scheme, not synthetic description of the structure of the world" (Hacker, 2013, p. 941).

25 This is argued more thoroughly in Morris and Dodd (2009).

26 Above all in Barcan Marcus (1993b).

27 Kripke's deep understanding of the issues is apparent already in the discussion of Barcan Marcus (1993b), which appears in Barcan Marcus (1993a, pp. 24–35).

28 The general point about the everydayness of essentialist talk is made in Barcan Marcus (1993c, p. 55).

29 And, of course, beyond them to Leibniz.

30 Note that realism about modality is implied by, but does not imply Lewis's well-known "realism about possible worlds" – the large view which is announced in Lewis (1973, ch. 4) and defended in Lewis (1986). This latter thesis also involves what I call *concretism* about possible worlds (see below) – and perhaps what I call *reductionism* about modality in addition.

31 We should mention here the work of Donald Davidson, who is not mentioned in the main text, but who was an influential figure at the beginning of the last quarter of the twentieth century, and for whom language was of central importance (see almost everything in Davidson, 1984). I take Davidson to be a kind of bridge figure: carrying on some of Quine's commitments (to extensionalism, for example, which itself looks as if it depends on a form of Humeanism); but also with a cultivated urbanity which made him accessible to the ordinary language tradition; and throughout adopting a form of semantic literalism.

32 So semantic literalism is not committed to what Heather Dyke calls the "representational fallacy," which she describes as "a general strategy of reading metaphysics off language" (Dyke, 2007, p. 7).

33 So semantic literalism is not committed to what Crispin Wright calls "the thesis of the priority of syntactic over ontological categories," according to which "the question whether a particular expression is a candidate to refer to an object is entirely a matter of the sort of syntactic role which it plays in whole sentences" (Wright, 1983, p. 51).

34 See Williamson (2007, p. 142). This approach evidently lies behind Williamson (2013).
35 This evidently dates back to Aristotle (1949). A recent exponent is Lowe (2006).
36 For the origin of the idea, see Plato (1901, 265e). For a contemporary use of it, see Sider (2011).
37 This is the general tenor of the argument of Keefe (2000, pp. 49–61).

Meaning and Truth-Conditions: From Frege's Grand Design to Davidson's

DAVID WIGGINS

1. However close it may have lain beneath the surface of some earlier speculations about language, the idea that to understand a sentence is to have grasped its truth-condition was first made explicit by Frege, for whom it was simply an unemphasized consequence of his general approach to questions of meaning. In the transition from logical positivism to modern analytical philosophy, the idea came near to being mislaid entirely. It was brought back into a new prominence in the late 1960s by Donald Davidson. Having rediscovered the idea for himself and in his own way, Davidson pressed its claims as a principle in the philosophy of mind and meaning, and as the only proper basis on which to conduct serious semantic investigations.

In advance of considering these and more recent claims about meaning, it will be useful to mark certain moments in the formulation and reformulation of the original insight of the truth-conditional theory. In a historical framework, even the bare skeleton of one furnished here, truth-conditional notions may be expected to transcend our more immediate sources of theory or doctrine concerning them as well as our more ephemeral disputations.

2. What is it for a declarative sentence to mean something, or have a sense? For Frege, to answer such a question was not, as it was later for Carnap or his inheritors, an all-important end in itself. Nor was answering that question a part of a comprehensive effort to arrive at a philosophical account of the relation of language to mind, as it is for Davidson and his inheritors. For Frege, it was a means, a propaedeutic for the understanding of the specific thing whose status and nature centrally concerned him, namely arithmetical judgments. Nevertheless, despite the special character of this original interest, Frege saw the question of the meaning of a declarative sentence as a general question, requiring not so much the introduction of a *calculus ratiocinator* (he said) as the creation of something more resembling a Leibnizian *lingua characteristica*. ("My intention was not to represent an abstract logic in formulas, but to express a content through written signs in a more precise and clear way."[1])

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

What Frege took the answer to his question to require was a general notion of meaning that could be correlative with the general idea of the understanding of a sentence. The conception he formed was of the *Sinn* or *sense* of a sentence that was to be understood thus or so, the sentence itself being seen as something built up by iterable modes of combination from component words, each of which had its own contributory sense. The senses of part and whole were to be such that the latter could be determined from the former (given an account of the modes of grammatical combination involved in the construction of the sentence).

The culmination of Frege's efforts may be found in Volume 1, §32 of the *Grundgesetze der Arithmetik*,[2] where he declares that there is both sense and reference for every sentence of his 'concept-writing' or 'ideography,' his *Begriffsschrift*. The *Begriffsschrift* is the constructed language whose operations are to shadow the workings of natural language and, in matters of difficulty such as the foundations of arithmetic, to regulate or supplant natural language. The reference of a sentence of *Begriffsschrift* is its truth-value, and the sense of the sentence is the thought that the sentence expresses.

But how exactly does a thought attach to a sentence? And what is a thought? Well, which thought it is that a sentence expresses and how the thought attaches to the sentence will depend upon nothing other than this: under what conditions is the sentence to count as true? Or, as Frege describes the matter for the artificial language he has just finished constructing:

> It is determined through our stipulations [for the linguistic expressions and devices comprising the language of *Begriffsschrift*] under what conditions [any sentence of *Begriffsschrift*] stands for the True. The sense of this name [of a truth-value, i.e. the sense of this sentence], that is the thought, is the sense or thought that these conditions are fulfilled…. The names [expressions], whether simple or composite, of which the [sentence or] name of a truth-value is constituted contribute to the expression of a thought, and this contribution [of each constituent] is its sense. If a name [expression] is part of the name of a truth-value [i.e. is part of a sentence], then the sense of the former, the name [expression], is part of the thought expressed by the latter [the sentence].

This statement comes at the end of Frege's detailed explanations of *Begriffsschrift*. But its import is potentially perfectly general, and the stipulations of sense for the expressions of his invented language simulate what it is for the expressions of a natural language to have a given or actual (not merely stipulated) sense. The institution of the *Begriffsschrift* – the project Frege had begun in preparation for his books on the foundations of arithmetic (1884; 1893) and published in part in 1879,[3] but then resumed and substantially corrected in the work of 1893, from which we have just quoted – at once illuminates natural language, albeit only in microcosm, and extends it. It illuminates it by displaying clearly the workings of a distinct language abstracted from natural language, namely the concept-script in which Frege hoped to make newly perspicuous all questions of "inferential sequence." The purposes this serves are akin to the practical and theoretical purposes that the construction of an artificial hand with a specialized function might have for a community of beings whose normal members had natural hands with less specialized functions.

3. Given Frege's concern with "a formula-language for pure [i.e., non-empirical] thought," it is unsurprising that, as he said, he "confined [him]self for the time being to expressing [within it] relations that are independent of the particular characteristics of objects"

(*Begriffsschrift*, 1879, preface). Properties and relations that were not so independent registered in the *Begriffsschrift* only in the form of generality-indicating letters such as Φ or Ψ that prescinded from all particular content.[4] Nevertheless, Frege did envisage successive relaxations of this ordinance, and he spoke of possible extensions of his formula language to embrace the sciences of geometry, motion, mechanics, and so on.

Given the universality and generality of the insights that originate with Frege, what we now have to envisage is a further extension of *Begriffsschrift*, namely the extension which, for purposes rather different from Frege's, will even furnish it with the counterpart of such ordinary sentences as "the sun is behind cloud" (say). In the very long run, the extended *Begriffsschrift* (Bg^+) might itself be modified yet further, to approximate even more closely to the state of some natural language. In the interim, however, in the transition from Frege's to our own purposes, it stands as an illustrative model of something much more complicated.

In an extension such as we are to imagine, a sentence like "the sun is behind cloud" will have a sense if and only if it expresses a thought. For the particular thought that the sun is behind cloud to attach to this English sentence (for it to attach to such a social artefact as this, produced and held fast in its temporal, historic, and social setting, Frege need not forbid us to say) will be for the sentence to be so placed in its total (historical and customary-cum-linguistic) context that it stands [in some situation] for the True just in case [in that situation] the sun is behind cloud. Putting the matter in a way that is not Frege's, one is tempted to say that he who understands the sentence is party to a practice that makes this the circumstance under which the sentence counts as true.

What mystery remains about what a thought is? The thought expressed by a sentence is expressed by it in virtue of ordinary linguistic practices (the practices that we have imagined will be encapsulated in the definitions or elucidations of the empirical terms to be introduced into the extended *Begriffsschrift*), which expose the sentence to reality, and its author to the hazard of being wrong, in one way rather than another way. Once you know that, you know what the thought is that sentence expresses.

4. The truth-conditional thesis, so seen, can be detached from more questionable features of Frege's semantical doctrine, such as the idea that a sentence is a complex sign standing for objects called the True or the False, or is a name of a truth-value. Wittgenstein does detach it (an act of retrieval for which he is too rarely commended) in *Tractatus Logico-Philosophicus* (1921):[5]

> 4.022 A sentence in use (Satz) shows how things stand if it is true. And it says that they do so stand.
>
> 4.024 To understand a sentence in use means to know what is the case if it is true.
>
> 4.062 A sentence in use is true if we use it to say that things stand in a certain way, and they do.

These are striking formulations, more general than Frege's and not radically dependent upon Wittgenstein's picture-theory of meaning. But now it seems we must attend to a problem that neither Frege nor Wittgenstein addressed explicitly. It is the problem (which still excites controversy in connection with Donald Davidson's version of the truth-conditional view of meaning[6]) that not just any true equivalence in the form [*s* is true if and only if *p*] can suffice to show that *s* actually *means* that *p*.

Suppose that the sentence "the sun is behind cloud" is now true. Then all sorts of other things have now (as matters stand) to be the case. It is daytime, the sun has risen, it is not

dark, more people are awake than asleep, and millions of automobiles are emitting smoke into the atmosphere, and so on – all this in addition to the sun's being behind cloud. For these are the accompaniments, in the world as it is, of its being daytime and the sun's having actually risen (to be obnubilated or not obnubilated). It is only to be expected, then, that, where *s* makes such a particular historical statement as it does, in a manner dependent upon some historical context, any of these extra things may in that context be added *salva veritate* to the right-hand side of the biconditional "*s* is true if and only if the sun is behind cloud and…." (It is certain that, without detriment to the truth of *s*, any necessary truth or natural law can be added so.) It is only by virtue of *knowing already* what *s means* that one would pick on the "sun is behind cloud" conjunct, from out of the mass of things that also hold when the "sun is behind cloud" is true, to be the clause to give the proper truth-condition for *s*. It follows that, to put down what a given utterance of a sentence *s* means and impart its meaning to someone, we need to be in a position to signal some 'intended' or 'privileged' or 'designated' condition on which its truth depends. Only where '*s* is true iff *p*' signals on its right-hand side an intended, privileged, or designated condition, can we conclude from this biconditional's obtaining that the utterance of *s* actually means that *p*. Look again at Wittgenstein's 4.024. His "what is the case if it [the sentence] is true" *presupposes* the identification of that intended or designated condition.

5. One way to advance might be to recast Frege's and Wittgenstein's thesis as follows:

> Sentence *s* has as its use to say that *p* – or *s* means that *p* – just if whether *s* is true or not *depends specifically upon* whether or not *p*.

But this is not really the end of the difficulty. For one of the things that the truth of "the sun is behind cloud" (as said at a given particular time and place) depends specifically upon, in one ordinary and standard sense of "depend," might perhaps (at that time and place) be low atmospheric pressure plus the obtaining of other meteorological conditions. None of this, however, is what the sentence actually says. And for the same reason we cannot improve the formulation just given by ruling that the truth of the sentence has to depend *only* upon the designated condition. It cannot depend 'only' on that condition, in the ordinary sense of "depend." For it will have to depend (in that ordinary sense) on everything that the satisfaction of the intended condition itself depends upon.

6. Consider now what Frege could have said in reply to this sort of difficulty, pointing to things already done in *Grundgesetze*. Suppose (as before), that the language of his *Begriffsschrift* has been formally expanded to enable one to say "the sun is behind cloud" and all sorts of similar empirical things. Let us call the imaginary extension (Bg^+). Each new primitive expression ('sun,' 'cloud,' etc.) will have had a reference stipulated for it in accordance with an empiricized extension of Frege's canon for definitions (see *Grundgesetze*, 1893, I, §33). In each case, the sense of the new primitive expression will consist in the fact that its reference is stipulated thus or so.[7] By virtue of this, it will have been contrived that the sense of any complex expression can be determined from its structure and from the referential stipulations governing each constituent expression. But now, in the light of all this, Frege is entitled to insist that, if we stick scrupulously to what actually flows from the full and appointed referential stipulations for all the individual expressions and devices of the extended *Begriffsschrifft* – let us call the set that consists of these stipulations $\Theta(Bg^+)$ – then we shall never arrive at an unwanted

biconditional such as 'the sentence "the sun is behind cloud on 25 June 1993" is true if and only if on 25 June 1993 the sun is behind cloud and the sun has risen and there is low pressure and more people are awake than asleep and …' (or its counterpart in Bg^+). For the stipulations for the extended *Begriffsschrift* furnish no way to derive such a biconditional. The intended condition will be the particular condition that the appointed stipulations deliver. Not only that. In concert, these stipulations, which license nothing about low pressure as part of the truth-condition for *s*, will *spell out* the specific particular dependence that had to be at issue in the restatement of the Frege–Wittgenstein thesis.

No wonder (Frege's philosophical champion may want to say) that we can hear '"the sun is behind cloud" is true if and only if the sun is behind cloud' as more or less equivalent to 'The truth of "the sun is behind cloud" semantically depends upon whether or not the sun is behind cloud.' For we can hear the biconditional '"The sun is behind cloud" is true if and only if the sun is behind cloud' as something delivered to us by whatever plays the part for English that the Fregean stipulations $\Theta(Bg^+)$ will play for the extended *Begriffsschrift*. Where the turnstile "$\vdash$" adjoined to '$\Theta(Bg^+)$' signifies that the stipulations Θ suffice to derive that which follows, what we are saying is, in effect, this:

[*s* means in Bg^+ that *p*] is equivalent to $\vdash_{\Theta(Bg+)}$ [True *s* if and only if *p*].

There is nothing strange or scandalous in the suggestion that we hear the conditional as enclosed or nested in this way within an operator "$\vdash_{\Theta(Bg+)}$" whose presence has to be understood. Countless conditionals we utter are intended by us to be understood as presupposing some norm or tendency that we could roughly identify but do not attempt to describe in the form of an explicit generalization. In so far as some residue of a philosophical problem still persists, the place to which it escapes is the characterization of "$\vdash$" and the general idea of a set of specifically referential specifications that imply this or that equivalence in the form [True *s* if and only if *p*]. The point that is left over, which we shall have to attend to in due course, is that, even though $\Theta(Bg^+)$ would *exemplify* such a set, $\Theta(Bg^+)$ could scarcely stand in for a general characterization of what a referential specification *is*. We need $\vdash_{\Theta(L)}$ for variable L.

7. The residual problem is philosophical – and serious. There is no immediate solution. We will return to the matter in §18 following, at a point decades later in our narrative. Meanwhile, let us consolidate the position now arrived at and pause here to show – if not in Frege's symbolism (which continues to daunt typesetters and readers equally) nor in strict accordance with every particular of Frege's own view of predication[8] – how, more exactly and in more detail, the claim might be made good that Frege can pick out the particular sort of dependence that he needs to secure between the truth of a particular sentence *s* of a language L and the obtaining of some condition that *p*. Let us do so by giving the referential specification of the semantics of a tiny sub-language L(1) of English that might be the counterpart of some small fragment of the extended *Begriffsschrift*.

Suppose the constituent strings of L(1) are simply the following:

(1) The sun is behind cloud
(2) Not (the sun is behind cloud), [which is said aloud as follows: the sun is not behind cloud]

(3) The moon is behind cloud
(4) Not (the moon is behind cloud), [which is said aloud as follows: the moon is not behind cloud],

together with all possible conjunctions of (1), (2), (3), and (4). Then we can determine the sense of an arbitrary string of L(1) by the following provisions:

Terms:	T(1)	"The sun" is a term and stands for the sun.
	T(2)	"The moon" is a term and stands for the moon.
Predicates:	P(1)	"Behind cloud" is a predicate and stands for being behind cloud.
Connectives:	C(1)	"Not" is a unary connective: where A is a string of L, "not" + A is true if and only if A is not true.
	C(2)	"And" is a binary connective: [A + "and" + B] is true if and only if A is true and B is true.
Syncategorematic Expressions:		"Is" is a syncategorematic expression, whose role it is to signal the fundamental mode of combination exemplified in R(1) below.
Rule of Truth:	R(1)	A sentence that is of the form [t + "is" + F], i.e., a sentence consisting of a term t, such as "the sun" or "the moon," followed by the syncategorematic expression, "is," followed by a predicate expression, F, such as "behind cloud," is true if and only if what t stands for has what F stands for[9] [that is to say that the reference of t has the property that F stands for].

Now let us put these rules together and note their effect. Given the sentence ["the moon" + "is" + "behind cloud"] = [The moon is behind cloud], we can agree, by R(1), that the sentence is true if and only if what "the moon" stands for has what "behind cloud" stands for, which last we can show to be true (see T(2) and P(1)) if and only if the moon is behind cloud. That does not make news – no more than news is made when, having multiplied 13 by 25 and got 325, you then divide 325 by 13 and get 25. But it verifies something. Similarly, as Davidson would point out here on Frege's behalf, our semantic derivation helps verify something, namely that, so far as they go, T(1), T(2), P(1), C(1), C(2), and R(1) represent a correct reckoning of the semantic resources of L(1).

What is achieved would have looked more impressive, no doubt, if L(1) had been a fragment of Chinese or Arabic and our referential specification had been done in English. Such a specification is something we can more easily imagine someone's failing to get right. There is no question, however, of a specification of this sort's looking impressive – or its needing to do so – unless it solves neatly and correctly a known grammatical difficulty or casts some light, however indirect, on a real obscurity in the workings of the language under analysis. The specification simply leaves nothing to chance in the idea that, where *s* is an L(1) sentence, *s* means in L(1) that *p* if and only if the biconditional [True *s* if and only if *p*] flows from $\Theta^{L(1)}$. In the context of Frege's own particular purposes in the *Grundgesetze der Arithmetik*, let this serve as a model for the defense of what Frege wanted to say there about

sentence sense. For all he needed to claim at 1.32 of that work was his complete control over the sense of a *Begriffsschrift* sentence. There is no relevant doubt, either theoretical or practical, of that grasp.

8. In *Tractatus* 4.024 Wittgenstein is heir to Frege's idea of sentence sense, and he tries to prescind from the particularities of *Begriffsschrift* in order to make a general claim. Nearby, at 4.002, he points to the need to bring real, live speakers into the picture. Once we take their presence seriously, however, we shall notice for ourselves a new kind of difficulty – the first of several that will come in due course to occupy us.

Consider the Latin sentence *alea jacta est*. Like its standard translation into English, *the die is cast*, the sentence is true if and only if a die [the die] has been thrown. This requires, *inter alia*, that there be a real die and someone who has thrown it. But it is safe to say that what speakers have normally used the Latin or the English sentence to state or to intimate – to say in the full and ordinary sense of 'say' – is nothing of that sort. The normal use of the sentence is to say the sort of thing that Julius Caesar said by *alea jacta est* when he broke the laws of the Roman Republic and, instead of disbanding his troops, led them towards Rome across the boundary marked by the river Rubicon. We who follow Caesar use the English sentence to assert that, in doing some act or other such as crossing that stream, we have committed ourselves irrevocably.

What is the difficulty here? The difficulty this creates for the Frege–Wittgenstein characterization of sense is that it shows that there is no simple route between the ordinary or normal use of a sentence such as "the die is cast" or "alea jacta est" – or from what people usually say by uttering it – and its strictly or narrowly linguistic meaning.

The proper response to this problem is to concede something. We must adjust the Frege–Wittgenstein thesis to read as follows:

> Sentence *s* has as its use in L(i) to say *literally* (to say in the thinnest possible acceptation of 'say') that *p* – thus *s* means that *p* in the narrowest strictest sense of 'means' – if and only if the referential specifications specific to the language L(i) [e.g., the sorts of specification given in §7] rule that whether *s* is true or not depends upon whether or not *p*.

This reformulation simply spells out an intention that Frege or Wittgenstein could have voiced. But what it suggests is that, in order to implement that intention, we have to embed our new formulation in some larger, more comprehensive theory, the sort of theory for which we have to look forward to the work of J. L. Austin.[10] This can persevere in the Fregean explication of the literal meaning of a sentence as consisting in its sense or truth-condition. But the fuller kind of saying that we find in the *the die is cast* example is something that the comprehensive theory will have to explain by building upwards and outwards from literal meaning as characterized after the fashion of provisions like T(1), T(2), P(1), C(1), C(2), and R(1). A neo-Austinian theory may suggest that, by doing the *rhetic act* of uttering something which has as its sense (and means literally) in language L(i) that the die has been thrown, and by performing thus the *locutionary act* of saying 'the die is thrown,' a speaker can perform a further speech act, namely an *illocutionary act*, tantamount in force to the declaration or intimation that he is irrevocably committed. By saying one thing then (here a false thing) Caesar conveys something else, which proves to have been a true thing.

9. There is more to say about this, but it only needs to be shown how one might place in a single focus the Frege–Wittgenstein conception of sense, in the condition in which it

was available by 1921, and the different researches of J. L. Austin. (See also Chapter 3, INTENTION AND CONVENTION IN THE THEORY OF MEANING, §3.) These were undertaken some 30 years after the *Tractatus*, in a framework of theoretical expectations both at odds with the concerns of *Grundgesetze* and *Tractatus* and uninformed by attention to very much that these works had in common. But the reason to mention the difficulty here is that, unless we are prepared to use Austin's work to *delimit* the area within which Frege, Russell, and the early Wittgenstein wanted to operate, their theories will be plagued with irrelevant objections. All will be well, however, provided that the theory of literal sense can be fitted into a larger framework that embraces among other things both the non-literal use of declarative sentences and the literal use of ordinary non-declarative sentences.[11]

At this point, let us attend to a passage too rarely heeded as already expressive of Wittgenstein's constant awareness of the importance of such a framework and of the wider frameworks that must contain this one. It occurs at *Tractatus* 4.002:

> Man possesses the ability to construct languages capable of expressing every sense, without having any idea how each word has meaning or what its meaning is – just as people speak without knowing how the individual sounds are produced.
>
> Everyday language is a part of the human organism and is no less complicated than it.
>
> It is not humanly possible to gather immediately from it what the logic of language is.
>
> Language disguises thought. So much so that, from the outward form of clothing it is impossible to infer the form of the thought beneath it, because the outward form of the clothing is not designed to reveal the form of the body, but for different purposes.
>
> The tacit conventions on which the understanding of everyday language depends are enormously complicated.

10. 4.002 presages some of Wittgenstein's later dissatisfaction with his Tractarian philosophy – and anticipates many of the preoccupations of later twentieth-century philosophy. But the thing that must immediately have troubled him about what he had written at 4.024 was the non-operational character of the conceptions of sense and truth that he had espoused in the *Tractatus*. By the time of *Philosophische Bemerkungen*, what he prefers to say is this:

> To understand the sense of a *Satz* means to know how the issue of its truth or falsity is to be decided. (*Philosophische Bemerkungen*, IV. 43). (Wittgenstein, 1975)

This new formulation looks backwards one decade at the doctrine of *Tractatus*, and sideways perhaps at the work of the Dutch mathematician L. E. J. Brouwer. But it is no less recognizable as the antecedent of the infamous claim advanced by the logical positivists of the 1930s – the claim that dominated the 1930s and 1940s and had an even longer period of influence in the philosophy of science – namely that the sense or meaning of a sentence is nothing more nor less than the method of its verification. (For further discussion of this, see Chapter 4, MEANING, USE, VERIFICATION.)

In the next phase of his thinking about linguistic meaning, Wittgenstein came to advance a different claim, namely, that ("for a large class of cases") to understand a linguistic expression is simply to grasp "its use in the language." (See the *Blue* and *Brown Books* and see the two decades' worth of philosophy books by other philosophers who were influenced by this formulation.) As verificationism fell out of favor, this doctrine rushed in to fill the vacuum

that was left by its disappearance.[12] Then, as the limitations came to be perceived of the doctrine of meaning as use, the next conspicuous contribution to the philosophy of meaning was Grice's idea that the meaning of a declarative utterance was a function of speakers' intentions to use that sentence to induce (by the recognition of that intention) this or that belief. (The trouble with that, one might think, was that such an intention was really the intention to *tell* someone something. It seemed to presuppose rather than to explicate the notion of *saying* that thing. It left too much to do under that head.)

The Fregean idea was destined to be rediscovered for philosophy and accorded an attention it had never previously enjoyed, but scarcely immediately.[13] For English speakers, it remained more or less buried until 1959, when Michael Dummett's article "Truth" (1959) disinterred it and put it back into circulation.[14] This limited circulation was yet further narrowed by the fact that Dummett expressed reservations of his own, not dissimilar to those we find in Wittgenstein, about the acceptability of the Fregean equivalence between sense and truth-conditions. (See Chapter 20, REALISM AND ITS OPPOSITIONS, §§1 and 2.)

11. So much then for the shift that Wittgenstein himself seems to have prompted away from the doctrine of *Tractatus* 4.024, and so much for the philosophy of language that had worked itself out over the period between 1921 and the 1960s, downstream of Frege, Russell, and early Wittgenstein, before Davidson's philosophy of language first became visible. But now let us go back to the point in the argument that we had reached at the end of §7.

In §7, having expounded *Grundgesetze* 1.32, we claimed that Frege or Wittgenstein would have been well placed to defend the truth-conditional thesis against the objections mentioned in §4 by formulating it as follows: in *Begriffsschrift* extended (Bg^+), *s* can be used to say literally that *p* if and only if the equivalence [True *s* if and only if *p*] flows from the referential stipulations for the language Bg^+. The difficulty that this left over was this: that the most that this positive doctrine will ever enable us to *put on the page* is an account of what it is for a sentence to say-in-the-language-of-Bg^+ that *p*, or

> *s* can be used to say-literally-in-Bg^+ that *p* – and *s* means-literally-in-Bg^+ that *p* – if and only if it is derivable from the referential-stipulations-for-Bg^+, specified thus …, that *s* is a true-Bg^+-sentence if and only if *p*.

This points at something general, namely the thing that Wittgenstein gets across in 4.024. But how can we articulate this general thing? How can we extricate "mean literally," "say literally," or "referential stipulation" from these hyphenations with "Bg^+"?

12. One manageable objective we might set ourselves is this: to arrive at the generalization we need by satisfying all the necessary conditions to supplant the constant "Bg^+" by a variable "L(i)." If we proceed in this way, how can we make explicit the thing that the Bg^+-relative condition only shows?

Looking back at what we then have to generalize and free from relativity to Bg^+, it will appear that the chief obligation we now incur is to dispense with the reference to particular stipulations such as T(1), T(2), P(1), …, and so on. Instead, we have to say explicitly what sort of thing a referential stipulation is. And perhaps the most natural first suggestion will be that we should advance on the following basis:

> *s* means that *p* in L(i) if and only if there is a Θ for L(i), namely $\Theta^{L(i)}$, that associates each expression of L(i) *with its proper value*, and this $\Theta^{L(i)}$ implies that *s* is true if and only if *p*.

Such a proposal will resonate in multiple ways with a common theme in a variety of semantical traditions. (Davidson calls it the building-block proposal.) The only trouble is that, in practice, it has never been brought convincingly to life. There is nothing both general and foundational to be said, simply in terms of reference, about how "and," "not," "Caesar," and "behind cloud" all have their meaning. We cannot dispense in semantics with something like the idea of reference. Equally, however, we cannot make out of the idea of reference the whole basis for the semantics of the sentence. From a standing start, we cannot even explain in such terms what distinguishes a sentence from a mere list. Frege himself never at any point dispensed with the idea of reference. But he also insisted, in the preface to *The Foundations of Arithmetic*, that "only in the context of a sentence does a word mean or stand for anything." Somewhere near the beginning of our account we have to render it more intelligible than this first suggestion will that sentences can be used not merely to list items of reference but to *say* things. Rather than start with the idea of reference, ought we not try to start at the other end, with truth itself and the *contributions* that the constituents of a sentence make to the conditions for its truth? On these terms, let the meanings of words be just as various as their contributions.

13. Noting that truth and meaning are symmetrically relativized to language in the elucidation of meaning we offered at the end of §11, we shall find a different suggestion we can explore. Not only did $\Theta^{L(1)}$ in §7 state the meanings of each sentence of the language L(1) and the meaning of [each] constituent of L(1). As a by-product of doing that, it fixed systematically and non-accidentally correctly the extension of the predicate "true" as restricted to L(1) sentences. Thus we have it that "'The sun is behind cloud" is true if and only if the sun is behind cloud, "The moon is behind cloud" is true if and only if the moon is behind cloud, and so on. (Such biconditionals are sometimes called *partial definitions* of 'true sentence of L(1).') We need not know which sentences are the true ones or constitute the actual extension of 'true-in-L(1).' But we do have a systematic way to state the principle on which that extension is assembled and, in that however strange or philosophically unwonted sense, we have a 'definition' of 'true-in-L(1).'

So the new thought is this: rather than arrive at an account of meaning by trying to generalize from the idea of designation, why not underwrite the *Tractatus* 4.024 generalization by saying the following?

> for any *s*, *s* can be used to say literally in L(i) that *p* – *s* means literally in L(i) that *p* – if and only if it is derivable from the definition of *true sentence of* L(i) that *s* is true if and only if *p*.

14. Having had recourse, in this last transposition, to the idea of a definition of truth in L(i), the time has come to turn our attention away from the main trend of semantic speculation in analytical philosophy, and away from Jena, Vienna, and Cambridge towards Lwow, Warsaw, and the study that Tarski called the "methodology of the deductive sciences," which was one part of Tarski's contribution to the prewar development of mathematical logic.[15]

The change of orientation is at first surprising. We are inclined but not necessitated in this direction by the formal shape of the problem we have been considering, which relates only to the conceptual lacuna that divides *Grundgesetze* 1.32 from *Tractatus* 4.024. Other directions are thinkable. Yet, given the actual influences that have formed the semantical speculations of nowadays (Davidson's and others), there is no real alternative – however oblique Tarski's concerns are to Davidson's, and however indirect our progress towards a general theory of linguistic meaning may appear.

Let us begin by asking the question how it can have come about, if the theory of Fregean sense was in no way Tarski's preoccupation, that Tarski should have been

interested in identifying a set of axioms for a language L(i) that delivered theorems given in the form [*s* is true in L(i) if and only if *p*]. Why was Tarski interested in axioms delivering the theorems of which philosophers of language such as Davidson and his associates were going to say that they determined the sense or contribution of each of the expressions of L(i)? The answer is that, even though Tarski was not interested in meaning as such, he was interested, and interested in a special way, in truth.[16] He was interested in the idea of truth neither after the fashion of the traditional logic – truth simply as the thing that valid inference preserves – nor after the fashion of philosophers who are exercised by the more mysterious and perennial questions about truth. The sort of thing Tarski was interested in doing was to find ways to compare and contrast the class of true formulas of a given formal language with the class of formulas that the rules and axioms *make provable* there. Embarking on inquiries of this kind, the thing that Tarski needed was a systematic account of what determined the extension of the concept *true*.[17] (Such a systematic account, given in what I have invited the reader to see as a modernization of the method of Frege's *Grundgesetze*, is what he called a 'definition.') But that was not everything he needed. He also needed to find assurance that his account of truth would not be undermined and discredited in the eyes of the community of mathematicians by the ancient paradoxes that exploited that idea, Epimenides's paradox, for instance (cp. Tarski, 1931, p. 110; 1936, p. 252).

Let us take the second of these problems first. Tarski's analysis of the liar paradox and its variants suggested to him that the best way to safeguard the construction he had in mind was to begin with some particular object-language that was itself free from all semantic notions. Once this object-language itself was made determinate, semantic concepts[18] such as satisfaction, truth, and designation,[19] as restricted to that object-language, could be introduced into the metalanguage for that object-language by defining each deliberately, with full formal correctness, in terms drawn from the object-language (or translations of the same into the metalanguage), from elementary set theory and from the formal morphology of the object-language, as given in the metalanguage.[20] On these terms, one could assure oneself that, if the object-language was immune from paradox, then the metalanguage that contained the object-language would be immune too.

15. So far so good. But on what principle was a restricted, paradox-free notion of truth, the concept *true sentence of L(i)*, to be positively characterized? What was the philosophical or intuitive substance of the idea? For his thoughts about this, Tarski turned (by his own account[21]) to his teacher Tadeusz Kotarbinski's book *Elementy Teorji Poznania* (1929), where we find the following passage (itself reminiscent of *Tractatus* 4.061):

> Let us pass to the classical doctrine and ask what is [to be] understood by "[a sentence's or thought's] accordance with reality." The point is not that a true thought should be a good copy or [fac]simile of the thing of which we are thinking, as a printed copy or photograph is. Brief reflection suffices to recognize the metaphorical nature of such a comparison. A different interpretation of "accordance with reality" is required. We shall confine ourselves to the following explanation: "John judges truly if and only if things are thus and so: and things are in fact thus and so."[22]

Spelling out this explanation for the case of some particular sentence, we have

> John judges truly in saying "snow is white" if and only if
> (1) John is right in saying "snow is white" if and only if snow is white
> (2) snow is indeed white.

But then it seems we can have, more simply[23]

> "Snow is white" is true if and only if snow is white.

The chief thing that it seems the definition of "true in L(i)" must do in order to conform to Kotarbinski's requirements is to imply one such equivalence in respect of each sentence of L(i).[24]

But now, having come this far, we shall be moved to ask: how otherwise can the definition of truth in L(i) furnish the thing Kotarbinski required than by doing the sort of thing we have seen that $\Theta^{L(1)}$ did? *This* is how Tarski's path comes to cross the path we have seen Frege's and Wittgenstein's thoughts as marking out. The parties are moving in different directions, but at the intersection there is one common thing each party needs in order to arrive where it is headed. Each party needs to involve itself, for any language that comes into consideration, in something like the exercise conducted in §7.

16. In the light of this, how is the problem to be solved of saying what a referential specification is? Well, if there is this convergence, then Tarski must have the same problem under a different name if he is to say what a definition of truth is. Tarski has to say what such a definition must be like in order to be adequate. The problem is solved as follows:

> A formally correct definition $\Theta^{L(i)}$ of the predicate "true" as applied to L(i) sentences is *materially adequate* if and only if, for every sentence *s* of L(i), Θ implies a biconditional (or so-called T-sentence) in the form [True *s* if and only if *p*], where '*p*' holds a place for a translation of *s* into the metalanguage ML(i).

Tarski calls this provision – which is evidently not itself statable at any level lower than the meta-metalanguage – Convention T.[25] It is simply the generalization of Kotarbinski's desideratum.[26] Similarly, then, each referential specification for L(i) assigns a value to every expression in L(i); and a set of such assignments is materially adequate under the very same condition as Tarski gives. It must yield a T-sentence for each sentence of L(i). And each T-sentence must in the same way be translational. This is to say that, in each case, 'p' must hold a place for a translation of *s* into the metalanguage.

17. Does this represent any progress? For Tarski, it is progress, because Tarski's only objective is to arrive at a non-accidentally and recognizably correct definition of true sentence of L(i). The word "translation" is not being used here in a manner that offends against Tarski's professed attitude to semantic notions. It occurs only in the meta-metalanguage, or (as one might fancifully say) in Kotarbinski's and Tarski's philosophy of truth. Occurring there, it presupposes only this: that a logician can recognize when the sentence given on the right-hand side of a T-equivalence is faithful to the meaning of the sentence mentioned on the left. Nevertheless, because Convention T includes within it a semantical term coordinate with the ideas of *meaning*, *definition*, and the rest, anyone who is concerned with the idea of meaning for its own sake still faces the same old question. How can we eliminate the semantical term "translation" from Convention T? Or how can we analyze or dismantle it there?

Here at last we can resume the story that we have already carried up to 1959, which was the moment, as we saw, when Michael Dummett put the truth-conditional insight back into circulation. If anybody had been concerned with the question of how to make Wittgenstein's generalization 4.024 work, then Tarski's construction would have served him perfectly – unless he had had such an obsessive concern with the nature of meaning itself that it was not sufficient to trace and explore the small circle that joins the ideas of truth,

meaning, and translation. Here though is the trouble, that, perfectly properly, *ex officio*, and by its nature, philosophy is imprisoned within that obsession.

18. To understand Donald Davidson's revival of the general idea of meaning as given by truth-conditions and the distinctive advance that this made possible, it helps to appreciate the immediate background of his speculations. This was not any concern on Davidson's part with the theory common to early Wittgenstein (to whom Davidson rarely, if ever, referred) and Frege (to whose doctrines Davidson evidently regarded Alonzo Church as the complete guide, even though this guide completely omitted all mention of Frege's truth-conditional insight). The background was more topical, namely Davidson's doubts about Carnap's methods of extension and intension,[27] his considered rejection of the answer to the question of linguistic meaning provided by H. P. Grice's reduction of semantic notions to psychological ones such as belief and intention,[28] and Davidson's attachment to the speculative framework furnished by W. V. Quine's book *Word and Object* (1960) – most especially the question of what a thinker from outside a community of speakers would need to avail himself of if he were to try to make sense of utterances in their unknown language. What Davidson wanted was to retain Quine's naturalistic approach to such questions, to align himself with Quine's objection to all "museum myths" of meaning, but to do so without commitment to Quine's talk of ocular irradiation, neural impacts upon subjects, and the rest. According to Davidson, the thing that impinges on subjects had better be the world itself, the world that is common to both interpreter and subjects.

Seeking for some framework within which to give a systematic account of the information (or putative information) that an interpreter would need to amass and draw upon in order to frame his hypotheses about the meanings of his subjects' uttered sentences, and seeking at the same time to sweep away the supposed obscurity of '*s* means that *p*,' the construction Davidson found himself reaching for was in effect none other than Tarski's. Davidson writes:

> Let us try treating the position occupied by '*p*' [in '*s* means that *p*'] extensionally: to implement this, sweep away the obscure 'means that,' provide the sentence that replaces '*p*' with a proper sentential connective, and supply the description that replaces *s* with its own predicate. The plausible result is
>
> (T) *s* is T if and only if *p*.
>
> It is worth emphasizing that the concept of truth played no ostensible role in stating our original problem [the problem of a theory of meaning for a given language]. That problem upon refinement led to the view that an adequate theory of meaning [for the language spoken by the interpreter's subjects] must characterize a predicate meeting certain conditions. It was in the nature of a discovery that such a predicate would apply exactly to the true sentences…. A Tarski-type truth definition supplies all we have asked so far of a theory of meaning. (Davidson, 1967)

The discovery is of course a rediscovery – the rediscovery of the thing that Frege and Wittgenstein had articulated and that Davidson failed to credit to Frege or to Wittgenstein. If Frege's original insight had not been correct, there could have been no such discovery. Working within Quine's framework, however, the attitude Davidson had towards Tarski was as follows. Taking translation for granted (or taking "means in L(i)" for granted), Tarski had defined "true sentence of L(i)." Conversely, then, why should not Davidson take truth in L(i) for granted, in order to define "means in L(i)"? The residual problem was then to dispense with Tarski's use of the word "translation."

19. Davidson's first thought about that problem seems to have been that he could secure everything he needed if he were simply to omit the requirement that the T-sentences generated by $\Theta^{L(i)}$ in the form [*s* is true if and only if *p*] should provide translations on the right-hand side of the L(i) sentence *s* mentioned on the left. Could he not stipulate instead that absolutely all the T-sentences that $\Theta^{L(i)}$ generated should be true? But it is now pretty clear that the condition is not sufficient.[29]

From the beginning of all Davidson's speculations, however, shaped as they were by Quine's *Word and Object*, the real solution to this problem was always at hand. Perhaps Davidson's best account of this solution is the one given in his "Radical interpretation" (1973).[30] But there is a real point here in giving a Davidsonian solution in a variant that is not open to the objections that so many critics have urged against the particularities of Davidson's own formulation.[31] The distinctive features of the variant presentation are chiefly due to Richard Grandy and John McDowell.[32]

If the interpreter of the utterance of a sentence is to say what it means, then he has to find out under what conditions the sentence, being the sentence it is, counts as true. To say so much is to say little more than Frege said. But the next thought one will have reaches beyond Frege. It is that linguistic behavior is a proper part of behavior. But, if so, there ought to be some other than purely simply semantic way of specifying what it is for a radical interpreter to succeed in interpreting alien subjects. Surely the interpreter's linguistic efforts are part of the larger effort to interact successfully with subjects, to coordinate his/her (the interpreter's) practical doings with those of subjects … in a word, to make sense of subjects and have them make sense of him/her. If we enlarge in this way, in terms which are not *specifically* semantical, upon what interpretation is attempting to achieve – and if we count the interpretation of speech as one proper part of the larger undertaking – then here at last we arrive at the substantive non-semantic constraint upon $\Theta^{L(i)}$ that we have been looking for:

> A definition of truth in L(i) will be materially adequate if it generates a T-sentence for each sentence *s* of L(i) and collectively the T-sentences that the definition implies, when experimentally applied to individual utterance by the speakers of L(i), advance unimprovably the effort to make total sense of the speakers of L(i).

The notion of total sense is not a semantic notion, but it *subsumes* one. One person's making sense of another is a matter of their participative interaction in a shareable form of life, of their homing upon the same objects, of their being in a position *ceteris paribus* to succeed in joint enterprises, and so on. In so far as we make sense of others, we deploy a mode of understanding that can be redescribed, however artificially, as follows. There is a store of everyday predicates of human subjects, of features of the environments that impinge on subjects, and of the events that are counted as the actions or conduct of such subjects. When we seek to attain participative understanding, we seek in response to circumstances, including the speech or conduct of subjects, to distribute predicates of these and other kinds across features of reality, mental states, and actions in such a way that: (1) the propositional attitudes we ascribe to subjects, specifying the content of these attitudes, are intelligible singly and jointly in the light of the reality to which we take subjects (or their informants, or their informants' informants …) to have been exposed; and (2) the actions (and actions of speaking) that we ascribe to subjects are intelligible in the light of the propositional attitudes we ascribe to them.[33]

In the form in which we now have it, the new elucidation of meaning finally bridges the gap between Frege's stipulations for his concept-script and Wittgenstein's bold generalization

of Frege's idea. Of course, it inherits all the well-known difficulties of the ideas of understanding, explaining, making intelligible, imaginative projection, or identification. But these difficulties are there anyway. The proposal not only depends upon these ideas. It assists us by helping to trace their interrelations.

20. The conclusion to which we have been drawn is that what it is for a sentence to mean that the sun is behind cloud and to be available to say that the sun is behind cloud, is as complicated as this. It involves a biconditional, "'The sun is behind cloud" is true if and only if the sun is behind cloud,' which is imbedded within the scope of an operator whose presence indicates that this biconditional is derivable from the whole system by which we make sense to one another and make sense of one another. What we have here is the idea of a significant language as a system that correlates strings of repeatable expressions with the states of affairs that the strings can draw attention to or get across, this system itself being a subsystem of the larger system by which social beings participate in their shared life. There is nothing abstruse in that. It is because we grasp it so readily (I think), both in philosophy and before philosophy, that we can hear a T-sentence given in the form "*s* is true if and only if *p*" as the output of such a system. When we grasp that, it is tantamount to our grasping something intuitively similar to the $\vdash_{\Theta(\mathrm{Bg}+)}$ that played the part we described in the Fregean elucidation of the meaning of *Begriffsschrift* extended sentences.

21. Objection may be made because, in the formulation I have set down here, *s* can only have it as its literal use to say that *p* if *all* suitably constrained theories imply that *s* is true if and only if *p*. What reason is there to suppose that this condition is non-vacuously satisfiable? The objection is a good one, because the formulation does seem to foreclose a matter that ought to have been left open. It seems better on reflection to postpone such questions until we have a fuller account of what it is to make sense of the shared life and conduct of L-speakers. This is a question of the indeterminacy of interpretation – or of translation, as Quine says. (See Chapter 26, INDETERMINACY OF TRANSLATION.) In the interim, perhaps we should rule that it is sufficient for *s* to mean that *p* that *some* putatively unimprovable theory that meets all the constraints should entail the biconditional [*s* is true if and only if *p*].

22. It may be objected that the idea of translation that our final proposal purported to remove surreptitiously returns with the idea of an interpreter's 'making sense' of other people. But to this the theorist of truth-conditions must reply by simply reiterating his claim that the idea of making sense that we find here is a much wider one than the idea of linguistic interpretation. The presence or absence of this more general thing can be demonstrated non-linguistically. The ideas of making sense of and being made sense of embrace and subsume the ideas of saying and the interpretation of saying, and they involve them illuminatingly with coeval, collateral ideas of explanation and understanding – even (as you may say, if you are as convinced as I am of the indispensability of these further things to the full story) with the idea of participation by interpreter and subjects in a shared form of life, and the idea of explanation as *Verstehen*.

23. A third objection might take the following form. After all the changes and emendations consequential upon earlier objections, should not all residues of the idea of compositionality itself have been expelled from the final formulation? "Truth itself is unduly emphasized in your construction," the objector may say. "One might accept this for argument's sake as the result of your foolish concentration upon declarative utterances. But, even in the cases where truth really does belong, it is surely not necessary to insist that the interpretive biconditional should be generated by the recursively or compositionally generated definition of truth that you envisage for the language L(i). If we are simply helping ourselves

now to the idea of what it requires to "make total sense" of speakers, *Verstehen* and the rest, why cling to this residue of Fregean compositionality?"

To this I would reply that the meaning we are interested in understanding is linguistic meaning, the non-natural meaning possessed by sentences that will be further saturated by context of utterance (etc.). It is the meaning with which sentences of what we recognize as languages are invested. (See Chapter 3, INTENTION AND CONVENTION IN THE THEORY OF MEANING, §5ff.) Generally speaking, what makes interpretation possible is the fact that the language to which the sentences belong can be treated as *pre-existing* any particular speaker or hearer and any particular act of communication. It is something that speakers and hearers need to know about already. The compositionality that theories of L(i)-sense or definitions of 'true sentence of L(i)' have to reflect is a property of the language L(i) itself, L(i) and its properties being something irreducible to any psychological, social, or pre-linguistic fact or facts about individual speakers or individual situations of communication.[34]

24. In opposition to such claims as the one just entered, many have tried to see the clauses of the definition of 'true sentence of L(i)' as answerable, in the last analysis, to psychological or neurolinguistic facts about speakers. After further reflection, some among those who are tempted by such an approach have shied away from the manifest embarrassments of getting involved in all that. And, backing off, they have preferred to say (as John Foster and Donald Davidson have more or less agreed in saying[35]) that the "theory" corresponding to the definition of true sentence of L(i) "explicitly states something knowledge of which *would suffice* for interpreting utterances by speakers of the language."[36] There are doubts about this kind of formulation. My own view would be that the question it answers should never have been permitted to arrive at the point where it could exact either this or any remotely similar answer. The thing the definition of truth for L(i) is answerable to is how things are with the social object that is the language L(i) – not how things are with the speakers past and present in virtue of whose existence that language is extant. The question for anyone who would define truth for L(i) is this: how have we to see L(i) – how must we parse it and segment it – in order to understand why its sentences mean this or that? How do we have to see L(i) in order to get principles by which we work out what its more complicated or obscure L(i) utterances mean? Again, why do L(i) sentences have to be translated into foreign tongues on *this* principle rather than that principle in order to arrive at a passable version of what was originally said? In so far as purposes such as working out what sentences mean and discerning principles of translation do not force us into one sort of grammatical description rather than another, there may be indeterminacy about the properties of L(i). But that is nothing new. Nor does it render it indeterminate which object the language L(i) is. L(i) is a historically given thing, changeable no doubt, and always in process, but a persisting social object nevertheless (see here Wiggins, 1997). It is not in any reprehensible sense an indeterminate or mythical object.

25. One last question. What, then, after all these twists and turns, was the advantage of going by the Tarskian route to our final destination? One alternative might have been to reflect that we never really define or reduce anything in philosophy. So someone might ask: Why not gloss the notion of meaning in a freewheeling fashion by simply using it and involving it with all the collateral notions that are imported by the idea of interpretation?[37] Such, after all, is the method of philosophical elucidation – the method we have learned not to hope to improve upon.

There is much to agree with in this objection – the Davidsonian account is an exercise in elucidation too – except that the one principal contention seems wrong. It seems wrong to

suggest that we should deny truth its foundational place in the elucidation of meaning. For there is a real advantage in going by the Fregean and Tarskian way. It is true that Tarski's construction, which consolidates Frege's, is conditioned in the first instance by Tarski's deep suspicion of primitive semantic notions, and this is a suspicion one may not share. But suspicion of the semantical as such is not the only possible reason one might have to applaud the fact that Tarski gives his construction in terms of simple truth (*not* truth in a structure/model),[38] that he introduces semantic notions deliberately and in a measured fashion, and defines notions like satisfaction and the valuation function (*) by fixing their extension. One may applaud all this not because one thinks semantic notions really *are* suspect, but because an account of meaning that builds on Tarski's construction *helps to show how meaning* is *possible*. By seeing the definition of 'true sentence of L(i),' for any language L(i) as needing to be built up in this careful and austere fashion, while the output of the definition is constrained in a manner that is irreducibly non-austere (as messy and anarchical as the social always will be), we can understand something about how it is possible for there to be such a thing as the semantical, and on what conditions it is possible, namely the existence of both the compositional (in the small) *and* the social (in the large).

Notes

1 "On the object of my concept-writing" (1883) in *Nachgelassene Schriften*, translated in *Posthumous Writings*. For the concept-writing itself, see *Begriffsschrift, eine der arithmetischen nachgebildete Formelsprache des reinen Denkens* (1879).

2 See *Grundgesetze der Arithmetik* (1893). In this work, §32 and the preceding sections consolidate, codify, and complete the doctrines of (direct) sense and reference explored and expounded in "Ueber Sinn und Bedeutung," pp. 25–50.

3 See *Begriffsschrift* (1879, n. 1).

4 In view of the confusion surrounding this mathematical term, Frege did not call them 'variables.'

5 *Tractatus Logico-Philosophicus* (1921). I translate *Satz* here not as 'proposition' but as 'sentence in use,' in order to mark and preserve the continuity (as well as the discontinuity) with Frege, who always used *Satz* to mean what we now mean by 'sentence.' I think Wittgenstein effectively answers the complaint that Frege has nothing to say about what it is to understand a sentence or grasp a thought. For this complaint – justifiable enough, perhaps, when directed against such traditional accounts as the one given in Church (see §04 of *Introduction to Mathematical Logic*, 1956) – see, e.g., Dennett, *The Intentional Stance* (1987, p. 123): "Frege does not tell us anything about what grasping a thought consists in …" In fact, it would be much fairer to complain against him (if one thinks this a matter for complaint) that, by introducing the thought as that which one grasps by virtue of grasping the acceptance/rejection conditions of something linguistic, Frege may seem poised to acquiesce, not in a vacuous Platonism of *noeta*, but in a potentially highly controversial quasi-linguistic view of thinking as the soul's internal dialogue with itself. Interestingly, this view really is Platonic: "The soul when it thinks is simply conversing with itself, asking itself questions and answering, affirming and denying…. So I define one's thinking as one's speaking – and one's thought as speech that one has had – not with someone else or aloud but in silence with oneself" (Plato, *Theaetetus* 189^{E}–190^{A}). On this and cognate matters, see now Dummett, "The philosophy of thought and the philosophy of language" (1986).

6 For Davidson's version, see "Truth and meaning" (1967). And see below §18. For various formulations of the difficulty explained in the text above and cognate apparent difficulties, see Ayer, "Truth" (1953); Wiggins, "On sentence-sense, word-sense, and difference of word-sense," (1971, pp. 18–19); Strawson, "Meaning and truth," inaugural lecture (1969); and Foster, "Meaning and truth theory" (1976). See also Davidson's "Reply to Foster" (1976), on which see below, n. 29.

7 Here I borrow an expository idea from Michael Dummett. See his *Frege: Philosophy of Language*, pp. 227–228.

8 For some discussion of these issues, see my "On the sense and reference of predicate expressions," with references there to V. Dudman and P. Sen.

9 For the use of the relative pronoun 'what' in connection with the references of predicates, see Frege, *Posthumous Writings*, p. 122. See also Dummett, *Frege: Philosophy of Language*, pp. 211–217.

10 For J. L. Austin's theory of locutionary, illocutionary, and perlocutionary acts, see *How to Do Things with Words* (1962). A rhetic act is an act of using vocables with a contextually determinate sense and reference and in such a way that one can be reported as saying that … For the connection between the locutionary and the rhetic, for the connection between Austin's researches and post-Austinian developments, and for much else besides that belongs in the areas I have so roughly blocked in, see Hornsby, "Things done with words."

11 If the inner core of a theory of sense for a given language is stated truth-conditionally, then the immediately adjacent next outer portion of that larger theory comprises the theory of the other linguistic moods of L(i). This will identify linguistic acts as acts of specifically *asserting that* [the sun is behind cloud, say], *asking whether* [the sun is behind cloud], or *enjoining* (again in the thinnest possible sense, and however vaingloriously in this particular case) *that* [the sun be behind cloud]. Cp. McDowell, "Truth conditions, bivalence and verificationism," p. 44, who assigns this task to a "theory of force." For the reasons why one might hive this task off from a theory of force in Austin's more general sense, see Davidson, "Moods and performances," pp. 109–121. See also Hornsby, "Things done with words."

12 My recollection from being an undergraduate at Oxford during the 1950s at the time when Austin was giving the lectures he then called *Words and Deeds* (1954–1955), but before the appearance of Grice's article "Meaning" (1957), is that in that period the doctrine then current about the meaning of words and sentences was simply a generalization of the Wittgensteinian thesis that meaning was use. There was no audible trace of the idea that to know the meaning of a sentence was to know what it would take for it to be true. To judge by my experience three years later in the Princeton philosophy department, the situation was very much the same in North America.

13 It is true that in the 1950s Frege's writings were being translated. But neither *The Foundations of Arithmetic* nor "On sense and reference" (the one paper which Carnap, Quine, Feigl, and Sellars had made familiar to all professional philosophers) explained what the sense of a sentence was to be. Nor did any of Geach's and Black's other *Selections*. It is true, too, that *Tractatus* 4.024 was legible enough. But, by its apparent archaism, the picture theoretical-framework obscured the doctrine.

14 Dummett, "Truth." It is noteworthy that in the several decades here under consideration, Wittgenstein's is the one clear philosophically salient formulation of the connection that Frege discerned between sense and truth-condition. Frege's doctrine on this point is conspicuous by its absence from expositions where we might have expected to find it, such as those of Alonzo Church at §04 of his introduction to *Introduction to Logic* (1956) and Rudolf Carnap at §33 of *Der Logische Aujbau der Welt* (1928). (For Carnap's own insufficiently remarked final return to a Fregean position, without explicit acknowledgment to Frege, see *Introduction to Semantics*, 1944, p. 22.)

I have wondered whether it is something connected with the blind spot I seek to explain in the text that accounts for the strange neglect of Richard L. Cartwright's definitive improvement (1954) of Quine's criterion of ontological commitment, namely his reformulation of this in terms of rules of truth. See Cartwright's "Ontology and the theory of meaning," an article that rehearses and resolves difficulties that were still under active discussion a whole decade later.

15 By "methodology of the deductive sciences" was meant, *inter alia*, the systematic study of such notions as *sentence*, *consequence*, *definition*, *deductive system*, *equivalence*, *axiom system independence*, *consistency*, and *completeness*.

16 See Tarski, "The concept of truth in formalized languages"; also "The semantic conception of truth" and "Truth and proof."

17 Having determined the extension of these concepts, of the true and the provable, he could then inquire whether they coincided. Tarski went on to show that the metalinguistic definition of 'provable in L(i)' – a purely syntactical notion – could be given within L(i); but that, for any L(i) of sufficient expressive power, the semantic paradoxes would obstruct the definition of 'true in L(i)' in L(i).

18 That is, as Tarski puts it, "concepts which, roughly speaking, express certain connections between the expressions of a language and the objects and states of affairs referred to by those expressions."

19 The extensionally defined counterpart of reference is the valuation or asterisk function as it is defined for each L(i). For the importance of not *beginning* by calling this function that of 'reference,' see McDowell, "Physicalism and primitive denotation."

20 The metalanguage is the language in which one may speak of whatever the object-language speaks of and also of the expressions of the object-language in their relation to that which the object-language speaks of.

21 See the Bibliography to Tarski, "The concept of truth."

22 *Elementy Teorji Poznania*, pp. 106–107 in the English translation. Note that neither Kotarbinski nor Tarski takes this schema to be the recipe for a redundancy, deflationist, or (as Tarski says) nihilistic theory of truth. Indeed, Tarski sometimes claimed to be coming to the rescue of the correspondence theory – though this claim must be taken with a pinch of salt. (Nothing in Tarski's theory can vindicate the idea that truth is to be defined in terms of a relation between sentences and states of affairs. Nor is there anything essential to the Tarskian construction that will vindicate the classical conception of truth as bivalent. Such questions remain open.)

23 For the claim about Tarski and Kotarbinski, see Wiggins, *Needs, Values, Truth*, pp. 333–334. (In addition to making general reference to Kotarbinski's book, Tarski refers also to lectures in Warsaw by Lesniewski. But the main burden of that acknowledgment seems to relate to the semantic paradoxes.)

24 For the failure of proposals to deliver this result by the method (which is not Tarski's official method) of simply conjoining 'partial definitions,' see Milne (1999).

25 Cp. "The concept of truth," p. 187. The words in the text above are an application of Tarski's doctrine, not a quotation.

26 Material adequacy is adequacy to the subject-matter, which is truth. It therefore entails *non-accidental* fidelity to the extension of the predicate. To think here of the material conditional/biconditional will excite precisely the wrong associations. See Tarski (1931, p. 129).

27 Davidson, "Carnap's methods of intension and extension."

28 See again Grice, "Meaning." See also Chapter 3, INTENTION AND CONVENTION IN THE THEORY OF MEANING.

29 It can be proved that, if there is one theory that provides a true T-sentence for each sentence of the language L(i), then there will automatically be a second such theory, and the interpretations to be read off the second theory will be different from those to be read off the first. See Evans and McDowell's editorial introduction to *Truth and Meaning* (1976). Their finding is not superseded by the footnote that Davidson added in 1982 to the *Inquiries* reprint of "Truth and meaning" (p. 26, n. 10) however illuminating the footnote might be in other ways.

30 See also Chapter 13, RADICAL INTERPRETATION.

31 Objections have mostly related to Davidson's free-wheeling use of the idea of an interpreter's needing to find what sentences a subject *holds true*. It must be noted, however, that Davidson has persisted in this part of his original presentation, and has developed it further in his Dewey lectures, *Journal of Philosophy* (1990).

32 See Grandy, "Reference, meaning and belief"; Evans and McDowell, editorial introduction to *Truth and Meaning*; McDowell, "Truth conditions, bivalence and verificationism," §1; and McDowell, "On the sense and reference of a proper name."

33 See McDowell, "On the sense and reference of a proper name."; also for some further suggestions, see Wiggins, *Sameness and Substance*, p. 222, and *Needs, Values, Truth*, ch. 4 (*ad init.*).

34 That is to say that I propose that one see language as a social object with a past, a present, and a future, something that is for each generation of speakers an *objet trouvé*, with words and modes of combination possessed contingently of this, that, or the other meaning. Languages are not, on this conception, abstract objects defined by their syntax or semantics. (As Nietzsche remarks, nothing with a history can be defined.) What the syntax and semantics (as of *t*) are answerable to is the state of this language (as of *t*), not the states of the speakers who aspire to speak that language.

35 See their respective contributions to Evans and McDowell, *Truth and Meaning*.

36 That is to say that they shy away from claiming that this is the theory that speakers actually use. Davidson, however (who has so much to lose from misunderstanding here), has not, when he has spoken of speakers and interpreter's 'theories,' exercised all the caution I should have counseled on this matter. See, for one instance among several, "A nice derangement of epitaphs."

37 See, e.g., the approach to meaning of Sainsbury, "Understanding and theories of meaning," pp. 127–144; and of Davies, *Meaning, Quantification, Necessity*.

38 On this point, see again Milne (1999).

Davidson has not only proposed an interpretive cum truth-conditional understanding of declarative meaning that inherits the role of Frege's account of these matters – on this consult his (1967), (1973), and (1976) – and made important suggestions about how we should bring the meanings of declarative and other utterances into a general framework – see his (1979). He has also made detailed proposals about the framing of truth-definitions for sub-languages of English that exemplify the difficulties posed by particular modes of combination, most notably the constructions involving reported speech and adverbial qualification. It will be instructive for anyone with an interest in the truth-conditional conception to consult some or all of his papers: "The logical form of action sentences," "On saying that," "Theories of meaning and learnable languages" (all in his *Inquiries into Truth and Interpretation*), and "Adverbs of action," in B. Vermazen and M. B. Hintikka (eds). *Essays on Davidson: Actions and Events* (Oxford: Oxford University Press, 1985).

In connection with these problems as well as with the broadly Davidsonian or neo-Fregean approach to meaning, the reader should study Evans and McDowell's editorial preface to *Truth and Meaning*, Evans and McDowell (eds) (1976); E. LePore (ed.), *Truth and Interpretation* (Oxford: Oxford University Press, 1986); Wiggins "'Most' and 'all': some comments on a familiar programme and on the logical form of quantified sentences," in M. Platts (ed.), *Reference, Truth and Reality* (London: Routledge and Kegan Paul, 1980); McDowell (1978).

Intention and Convention in the Theory of Meaning

STEPHEN SCHIFFER

What is the relation between language and thought – or, more exactly, between the representational, or intentional, characteristics of language and those of propositional attitudes such as believing and intending? An answer many find attractive is that we must "explicate the intentional characteristics of language by reference to believing and to other psychological attitudes" (Chisholm, 1958, cited in Speaks, 2010). In other words, it is only our intentional mental states – believing, intending, and the like – that have *original* intentionality, intentionality that doesn't have its source in something else's intentionality; the intentionality of words and speech acts is *derived* intentionality, intentionality inherited from that of associated mental states. That answer raises two questions: how is the original intentionality of thought to be explained, and how does the intentionality of language "derive" from the original intentionality of thought? The focus of this chapter will be on the second question, although the first question can't be ignored entirely, and I shall touch on it in the final section of this chapter.

Although many philosophers seem to accept the derivation view, hardly any of them attempt to spell out how it works. In fact, I can think of only two programs that attempt to explain how the intentionality of language reduces to that of thought, and only one of these programs ventures to reduce all questions about linguistic representation to questions about mental representation. The more ambitious program is one that derives from the Grice-inspired program of intention-based semantics (IBS); the other derives from David Lewis's project of defining what I shall call the *public-language relation*. I shall start with a reconstruction of Lewis's account of the relation in *Convention* (Lewis, 1969) because a problem that immediately arises for that account provides a natural segue to the more ambitious IBS project.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

1 Lewis on the Public-Language Relation

Hardly any philosopher of language would deny that if something is an expression which has meaning in a population, then that is by virtue of facts about the linguistic behavior and psychological states of members of that population. Philosophers of language would like to know which facts those are. They would also like to know what it is for something to be the language of a population. The two questions are apt to seem very closely related, for it's apt to seem that an expression has a certain meaning in a population just in case it has that meaning in the language of that population. If one both thinks of a language as a "pairing of sound and meaning over an infinite domain" (Chomsky, 2006, p. 92) and accepts that an expression *e* has meaning just in case there is something *x* such that *e* means *x*, then one may think of a language as a function – doubtless a finitely specifiable function – that maps finite sequences of sounds or marks (or whatever) onto meanings (or, to accommodate ambiguity, sets of meanings). Then, if *L* is such a function, we may say, first, that

$$e \text{ means}^* x \text{ in } L \text{ iff } L(e) = x$$

(where '*' is to remind us that this stipulated sense of 'means*' isn't the use-dependent notion of meaning that philosophers struggle to understand), and then, second, that

$$e \text{ means } x \text{ in } P \text{ iff, for some } L, L \text{ is a language of } P \text{ and } e \text{ means}^* x \text{ in } L.$$

A language, thus conceived, pairs the words, phrases, and sentences of a language onto the things they mean* in the language. That is bound to seem inevitable, for isn't the meaning of a sentence determined by the meanings of its constituent morphemes in conjunction with the semantic import of the syntactic structures deployed in the sentence? And doesn't that thought lead inexorably to the thought that an account of expression-meaning must first say what it is for a morpheme to have a certain meaning and what it is for a syntactic structure to have a certain semantic import, and to do that in a way that will determine a meaning for every expression of the language? If that is one's sense of how things must be, then the project of saying what it is for a function of the kind just described to be the language of a population ought to strike one as bewilderingly complex. Where is one even to begin, and how could one possibly complete the project without being able, first, to specify a generative grammar for the language, where that is a finitely specifiable theory of the language that generates one or more syntactic structures for each expression of the language and interprets those structures both phonologically and semantically, and then, second, to specify the myriad interlocking practices whereby the morphemes and structures of the language would come to mean in the population what by stipulation they mean* in the language? Anyone who has banged her head against the apparent inevitability, and then the apparent impossibility, of that approach must appreciate the genius and simplicity of David Lewis's way of cutting through that Gordian knot.

In presenting the views I will discuss in this chapter my focus will be on their essential plot lines, and I will simplify like crazy in order not to get bogged down at every turn with technical complexities. To that end I will pretend that the languages we speak have no indexicality, ambiguity, or moods other than the indicative, and that the meaning of a sentence is a proposition, in the generic sense of an abstract, mind- and language-independent entity that has a truth-condition, which it has both necessarily and absolutely (i.e., without

relativization to anything else; see Schiffer, 2003, ch. 1). Relative to those simplifications, I will say that a *Lewis-language* is any function L from finite sequences of sounds or marks (or whatever) – the "sentences" of L – onto propositions. This allows us to say not only that a sequence σ means* the proposition q in the Lewis-language L just in case $L(\sigma) = q$, but also that:

> For any Lewis-language L and sequence of sounds σ, σ is *true* in L iff for some q, σ means* q in L and q is true.

Now a language may be used in any number of ways. For example, a language whose "sentences" are sequences of neural activity may function as a person's language of thought. David Lewis's interest in *Convention* is in a population's using a language as a public language of communication, a language they use to communicate with one another, and his book aims to say what relation must hold between a Lewis-language L and a population P in order for it to be the case that P uses L as a public language of communication. Let's call that relation, whatever it turns out to be, the *public-language relation*. If L is the language members of P use as their medium of communication, then every sentence of L will mean in P what it means* in L. Since the meaning a sentence has in a population is the use-dependent notion of sentence-meaning philosophers want to understand, an account of the public-language relation would be an account of the use on which a sentence's meaning depends, provided that the languages we speak really are Lewis-languages. If they are, and if the only intentionality involved in the account of the public-language relation is that of propositional-attitudes, then the account would have succeeded in defining the intentionality of sentences in terms of the intentionality of thought.

Lewis's definition of the public-language relation in *Convention* is the following, minus an addendum which I will get to presently:

> For any Lewis-language L and population P, L is a public language of P iff there prevails in P a convention of truthfulness in L.

Roughly speaking, a convention for Lewis is a regularity in behavior to which the members of a population want to conform if (nearly) everyone else in the population conforms, and to which they do conform because it's common knowledge among them that they expect one another to conform. Such regularities are self-perpetuating in that past conformity gives rise to the expectation of conformity, which gives rise to future conformity.

In *Convention*, Lewis said that

> It is *common knowledge* in a population P that ___ if and only if some state of affairs A holds such that:
>
> (1) Everyone in P has reason to believe that A holds.
> (2) A indicates to everyone in P that everyone in P has reason to believe that A holds.
> (3) A indicates to everyone in P that ___. (Lewis, 1969, p. 56)

I independently introduced a similar notion in *Meaning* (Schiffer, 1972), which I called *mutual knowledge*,[1] and said that x and y mutually know q just in case x knows q, y knows q, x knows that y knows q, y knows that x knows q, x knows that y knows that x knows q, and so on, and I proposed finite conditions for the generation of mutual knowledge. The

generalization to the *n*-person case is obvious, but for mutual knowledge in a population whose members aren't all acquainted with one another, I in effect proposed that *q* is mutual knowledge in *P* just in case everyone in *P* knows *q*, everyone in *P* knows that everyone in *P* knows *q*, and so on (Schiffer, 1972, §II.2). In his (1975) Lewis revised his account of common knowledge and said that a proposition is "*common* (or *mutual*) *knowledge* [in *P* just in case it] is known to everyone [in *P*], it is known to everyone [in *P*] that it is known to everyone [in *P*], and so on," but he added that the knowledge may be "merely potential: knowledge that would be available if one bothered to think hard enough." Conformity to a convention of truthfulness in *L* requires one not to utter any sentence of *L* unless it's true in *L*, but because "truthfulness-by-silence is truthfulness" (Lewis, 1969, pp. 165–166), it's not enough for a convention of truthfulness in *L* to prevail in *P* that members of *P* never utter sentences of *L*; in order for a convention of truthfulness to prevail in *P* members of *P* must regularly utter sentences of *L* and (for the most part) utter them only when they believe them to be true.

A striking feature of Lewis's account of the public-language relation is that, while it yields a definition of a sentence's having a certain meaning in a population, it says nothing at all about the meanings of words, nor does it say anything about a sentence's meaning being determined by the meanings of its constituent words and the semantic import of its syntactical construction. Lewis of course is well aware of the fact that:

> Not just any arbitrary infinite set of verbal expressions will do as the set of sentences of an interesting language. No language adequate to the purposes of its users can be finite; but any language usable by finite human beings must be the next best thing: finitely specifiable. It must have a finite grammar, so that all its sentences, with their interpretations, can be specified by reference to finitely many elementary constituents and finitely many operations for building larger constituents from smaller ones. (Lewis, 1969, p. 166)

He also of course recognizes that words as well as sentences have meanings for those who use them, and that the meaning of a word is determined, in so far as it is determined, by the way those for whom it has meaning use it. Why then doesn't Lewis define language in a way that requires a language to have a grammar, so that if a language *L* is used by a population *P*, then *L*'s words will have in *P* whatever meanings the grammar for *L* assigns them? Lewis explains that, while a grammar for *L* uniquely determines *L*, *L* doesn't uniquely determine any grammar: more than one grammar will determine *L*, grammars that may differ in the meanings they assign to the morphemes of *L* or even in what they recognize to be the morphemes of *L*. This presents Lewis with a problem:

> Given *P*, we select *L* by looking for a convention of truthfulness; but given *L*, how can we select [its grammar]? Conventions of truthfulness pertain to whole sentences and leave the interpretations of parts of sentences undetermined. Perhaps we should look for conventions of some other kind, but I cannot think what the content of such a convention might be. (Lewis, 1969, p. 198)

Well, perhaps the correct grammar for *L* is determined by something other than a convention. Lewis considers the Chomskian conjecture that the correct grammar for a language is the one that enters into the explanation of the linguistic competence of its users, but he rejects using that psycholinguistic hypothesis in defining the public-language relation; for

even if it's true, he says, it's a contingent truth, and thus can't be part of an *analysis* of '*L* is used by *P*,' "since the analysandum clearly could be true although the analysans was false" (Lewis, 1975, p. 178). Lewis is forced to conclude that he knows "of no promising way to make objective sense of the assertion that a grammar Γ is used by a population *P* whereas another grammar Γ′, which generates the same language as Γ, is not" (Lewis, 1975, p. 177).

As I have so far presented Lewis, one may be puzzled as to why he thinks grammars pose a problem for him. Why not identify languages with what he calls grammars, namely, finite specifications of the functions he now calls languages? Such a grammar may be conceived, at least initially, as a function that maps each expression of the language it determines onto its meaning in the language, and does so in a way that reveals how the meaning of every semantically complex expression is determined by its syntactical construction and the meanings the function assigns to the morphemes from which the complex expressions are constructed. Let L_G be such a Lewis-language-cum-grammar. In the functions Lewis defines as languages, each sequence of sounds in the function's domain is a sentence of the language. The sequences of sounds that constitute the domain of L_G will include words and other sub-sentential expressions along with sentences. If, for any ε and μ, $L_G(\varepsilon) = \mu$, then we may say that ε means* μ in L_G, and if L_G is a public language of population *P*, then ε means μ in *P*. For Lewis, a grammar determines the language of which it's a grammar, but a language doesn't determine its grammar. Since L_G is what Lewis calls a grammar, we would have a conception of language that does determine its grammar. Now suppose Lewis were to say that L_G is a public language of *P* just in case there prevails in *P* a convention of truthfulness in L_G, where, as before, there prevails in *P* a convention of truthfulness in L_G just in case it's common knowledge in *P* that its members try not to utter any *sentence* of L_G unless it's true in L_G, and so on. Then, provided the languages we speak are Lewis-languages, we can say what it is for a word *w* to mean μ in *P*: it means that just in case for some language L_G, L_G is a public language of *P*, *w* is a word in L_G, and $L_G(w) = \mu$. A Lewis-language maps only sentences onto meanings; let's call a finitely specifiable function L_G which maps expressions of every syntactic category onto a meaning a *Chomsky-language*. Every Chomsky-language determines a unique Lewis-language, but a Lewis-language determines no unique Chomsky-language. If there prevails in *P* a convention of truthfulness in a Lewis-language, then we have no way of saying that any grammar of the language is the grammar used in *P*. But if there prevails in *P* a convention of truthfulness in a Chomsky-language, then it follows that a particular grammar for a particular Lewis-language is used in *P*. We get that result simply by virtue of the fact that all it takes, according to Lewis, for there to be a convention of truthfulness in L_G in *P* is that it be common knowledge in *P* *that, for any sentence* σ *of* L_G *and proposition q, members of P try not to utter* σ *unless* $L_G(\sigma) = q$ *and q is true*, and so on.

Lewis didn't overlook this easy way of securing that a Chomsky-language is used in a population: he had already ruled it out by a stipulation he had made along the way about how the just-cited common knowledge condition was to be understood. Lewis says that a function *L* from finite sequences of sounds or marks – the "sentences" of *L* – into propositions is a public language of a population *P* only if it is common knowledge in *P* that members of *P* try never to utter a sentence of *L* unless it's true in *L*. But wouldn't such knowledge require ordinary speakers to know propositions of the form $L(\sigma) = q$, and wouldn't that require those ordinary speakers to know some set theory? And, just as bad, wouldn't knowing such propositions require them to have a finitely specifiable way of thinking about the function *L*, and wouldn't that be tantamount to knowing a grammar for *L*? Lewis has no doubt that ordinary

speakers have no such knowledge, and to avoid having it required by the common knowledge required for them to use a language, he first distinguishes between two ways in which the common knowledge in question might obtain in:

> It's common knowledge in *P in sensu composito* that there prevails in *P* a convention of truthfulness in *L* iff it's common knowledge in *P that for any σ, q such that L(σ) = q, a member of P won't utter σ unless she thinks q is true*.
>
> It's common knowledge in *P in sensu diviso* that there prevails in *P* a convention of truthfulness in *L* iff for any σ, *q* such that $L(\sigma) = q$, it's common knowledge in *P that a member of P won't utter σ unless she thinks q is true*.[2]

In other words, when the common knowledge is *in sensu composito*, what is known requires members of *P* to have a conception of *L* and enough knowledge of set theory to know propositions of the form $L(\sigma) = q$, whereas when the common knowledge is *in sensu diviso* members of *P* needn't have any way of thinking of *L* or any knowledge of set theory; they merely have to have the right expectations when sentences of *L* are uttered, so that if $L(\sigma) = q$ and a member of *P* hears another member of *P* utter σ, then she will expect him to believe *q*. "The common man," Lewis says, "need not have any concept of *L* in order to expect his fellows to be truthful … in *L*. He need only have suitable particular expectations about how they might act … in various situations" (Lewis, 1975, p. 180).

Now that we know why Lewis thinks he can say what it is for a sentence, but not for a word, to mean something in a population, and now that we have a better understanding of what, according to him, must be the case in order for a convention of truthfulness to prevail in a population, we are positioned to assess his claim that:

> For any Lewis-language *L* and population *P*, *L* is a public language of *P* iff there prevails in *P* a convention of truthfulness in *L*.

There are, I believe, at least two problems with this account.[3] The first is that if there prevails in a population a convention of truthfulness in any language, then there will also prevail in that population conventions of truthfulness in infinitely many languages that are not public languages of the population. Suppose, for example, that English is the public language of *P*. Then members of *P* will regularly utter sentences of English, and when they do they will, for the most part, believe those sentences to be true. But only a finite number of the infinitely many English sentences will ever be uttered. Suppose ξ is an English sentence so convoluted and long that no one could reasonably expect it ever to be uttered. Then it will be obvious to any member of *P* who considers ξ that no member of *P* would utter it, and, *a fortiori*, for any proposition *r*, obvious that no member of *P* will utter ξ unless *r* is true. As noted earlier, with respect to the sentences of a population's language that will never be uttered, the truthfulness that obtains is truthfulness-by-silence. But now let Gobbledygook be a language that coincides with English with respect to every sentence that might be uttered but departs wildly from English thereafter: the sentences in Gobbledygook but not in English may be composed of words that aren't in English, or, if Gobbledygook and English have the same sentences, then the sentences that no one would ever utter have meanings in Gobbledygook that are entirely different from the meanings they have in English. Since it will be common knowledge (*in sensu diviso*) in *P* that members of *P* regularly utter sentences of Gobbledygook and that when they do they intend to be truthful in

Gobbledygook, and that they will be truthful-by-silence as regards the sentences of Gobbledygook that they know no one in *P* would ever utter, it follows by Lewis's definitions that there prevails in *P* a convention of truthfulness in Gobbledygook – a language that is not a public language of *P*.[4] And since infinitely many languages satisfy the description of Gobbledygook, it follows from Lewis's definitions that infinitely many languages constitute counter-examples to his definition of the public-language relation.

I mentioned this problem to Lewis in 1968; he acknowledged that it showed that his definition failed to provide a sufficient condition, but he couldn't at the time find a revision that avoided the problem. That may seem surprising. The counter-example works only if one takes '$\neg A$ unless B' to be equivalent to the material condition '$A \rightarrow B$,' which one can know to be true merely by knowing that A is false. But if Lewis were to say instead that the common knowledge is of the *counterfactual* proposition *that if a member of P* ***were*** *to utter ξ, then she* ***would*** *think that q was true*, then Gobbledygook wouldn't be a counter-example to the definition, for if, for any σ, $G(\sigma) \neq E(\sigma)$, then no member of *P* would expect a member of *P* to mean $G(\sigma)$ if she were to utter σ, for they wouldn't know to associate that proposition with σ. The problem with this thought, however, is that there are also infinitely many English sentences that members of *P* wouldn't be able to understand – sentences like 'Buffalo buffalo buffalo buffalo buffalo buffalo buffalo buffalo buffalo,'[5] in addition to the infinitely many English sentences whose length or convoluted structure make them impossible to process. In "Language and languages" (Lewis, 1975), Lewis proposed a certain way of avoiding the problem, but then in "Meaning without use: reply to Hawthorne" (Lewis, 1992), he recognized that that solution to what he now called the *meaning-without-use problem* didn't work, and proposed a third account of the public-language relation that, as we'll see in §4, may also be problematic.

The second objection to *Convention*'s account of the public-language relation also shows that that account fails to provide a sufficient condition for a language to be a public language of a population. The problem is that if it were a sufficient condition for *L*'s being a public language of *P* that there prevailed in *P* a convention of truthfulness in *L*, then virtually *every* convention would count as a convention of truthfulness in a language, and this by virtue of the fact that every (or virtually every) convention requires certain actions to be performed when certain conditions obtain. For example, suppose that in monastery *M* there is a convention to recite prayer *A* on Monday, prayer *B* on Wednesday, and prayer *C* on Friday, and not to recite those prayers on any other days. Now let $L^{\dagger}$ be that function such that:

$$\forall x, y \left[L^{\dagger}(x) = y \text{ iff } (1)\ x = \text{reciting } A\ \&\ y = \text{the proposition that it's Monday or } (2)\ x = \text{reciting } B\ \&\ y = \text{the proposition that it's Wednesday or } (3)\ x = \text{reciting } C\ \&\ y = \text{the proposition that it's Friday}\right]$$

Then $L^{\dagger}$ is a Lewis-language and there prevails in *M* a convention of truthfulness in $L^{\dagger}$, and Lewis is committed to saying that $L^{\dagger}$ is used in *M* as a public language of communication. But since the members of *M* never use $L^{\dagger}$ to communicate anything (at least to one another), it's clearly not used as a public language of communication (or as any other kind of language). I mentioned this problem, too, to Lewis in 1968; he agreed that it was a counter-example to his definition and changed that definition to:

> For any Lewis-language *L* and population *P*, *L* is a public language of *P* iff there prevails in *P* a convention of truthfulness in *L, sustained by an interest in communication*,

which is the definition that appeared in *Convention* when the book was published. The revision, however, doesn't do the job: prayers *A*, *B*, and *C* might all be for greater powers of communication; yet that still wouldn't make $L^{\dagger}$ a language the monastery uses as a public language of communication. A convention must forge a considerably tighter connection to communication if it's to succeed in defining the public-language relation; it would at least have to secure that sentences of the language it concerns are uttered in order for speakers to mean what the sentences mean* in the language. This is our segue to the Gricean program of intention-based semantics.

2 Intention-Based Semantics

This is a program for reducing all questions about the intentionality of speech acts and linguistic expressions to questions about the intentionality of thought. It takes as foundational in the theory of meaning a certain notion of *speaker-meaning* and seeks to define it, without recourse to any semantic notions, in terms of acting with certain audience-directed intentions. Then it seeks to define other agent-semantic notions – most notably, speaker-reference (the notion of a *speaker*'s referring to a thing, as contrasted with an *expression*'s referring to it) and illocutionary acts[6] – in terms of its defined notion of speaker-meaning.[7] With that done, Gricean IBS then sets out to define the semantic features of linguistic expressions wholly in terms of its defined notion of speaker-meaning, together with ancillary notions, such as that of *convention*, which are themselves explicable wholly in terms of non-semantic propositional attitudes. Since expression-meaning is defined in terms of speaker-meaning and convention, and speaker-meaning and convention are defined in terms of non-semantic propositional attitudes, it's supposed to follow that expression-meaning is also defined in terms of non-semantic propositional attitudes.

There is disagreement among Griceans as to how exactly the definition of speaker-meaning should go, but there may be little reason to care about how to define a notion of speaker-meaning if that notion can't be used to define the semantic features of linguistic expressions, and in this regard a reader of Grice's 1957 article "Meaning" has a right to be puzzled. Grice spends nearly all of that article building up to his famous proposal that *S* meant something in "uttering" *x* iff *S* "intended the utterance of *x* to produce some effect in an audience by means of the recognition of this intention,"[8] and it is only at the very end of the article that we get anything about expression-meaning. But then all we get are two equivalences baldly presented without any elaboration. The first is that:

> '*x* meant something' is (roughly) equivalent to 'Somebody meant something [in uttering] *x*.'

For example, if Gretel rolls her eyes to communicate to Hansel that the speaker is a pretentious bore, then, by the definition, Gretel's eye rolling meant something. The second generalization is that:

> '*x* means (timeless) that so-and-so' might as a first shot be equated with some statement or disjunction of statements about what "people" (vague) intend (with qualifications about "recognition") to effect by *x*.

There are four things one is apt to find puzzling. First, Grice has made no effort to show how these definitions are motivated by his definition of speaker-meaning. Second, the

equivalence offered for '*x* meant something' seems not to be an analysis of any obvious pre-theoretic notion, but is more in the nature of a stipulation whose theoretical purpose hasn't been revealed. Third, there is no mention of word-meaning. And fourth, the second equivalence, which is intended to cover indicative sentence meaning, appears to ignore the fact that every natural language has infinitely many sentences that will never be, or even could be, uttered. So why is Grice's article so famous and thought by many to be of such importance? Does the importance of Grice's article reside wholly in his suggested account of speaker-meaning, never mind any relevance that account might have for an account of expression-meaning?

No; those who perceived Grice's article to be important did so because they took themselves to discern in his account of speaker-meaning an *invisible hand* that guides them from the intentions that define speaker-meaning to an account of expression-meaning in terms of those intentions. Any Gricean account of speaker-meaning could be used to make the invisible hand visible, but I will use the account of assertoric speaker-meaning implicit in Grice's 1957 article. According to that account:

> For any person *S*, proposition *p*, and utterance *x*, *S* meant *p* in uttering *x* iff, for some person *A*, *S* uttered *x* intending
>
> (1) *A* to believe *p*;
> (2) *A* to recognize that *S* uttered *x* intending (1);
> (3) *A*'s recognition of that intention to function as part of *A*'s reason for believing *p*.

Quite apart from the question of whether this is in any way "correct," its proper understanding requires seeing the answers Grice assumed to two questions raised by the definition. One question was how *A*'s recognition of *S*'s intention to get *A* to believe *p* was supposed to function as part of *A*'s reason for believing *p*. The intended answer was that *A* would infer from the fact that *S* uttered *x* intending *A* to believe *p* that *S* believed she knew *p*, and then, taking the fact that *S* believed she knew *p* to be very good evidence that *p* was true, infer *p* from that fact.[9] The other question raised by the above displayed definition was how *A* was to recognize that *S* uttered *x* intending *A* to believe *p*. Understanding how that recognition was supposed to work is essential to understanding the invisible hand that was supposed to guide one from the account of speaker-meaning to an account of expression-meaning. It was supposed to work like this: when *S* utters *x* in order to mean *p*, there is some feature φ such that *S* intends *x* to have φ and intends *A* to recognize that *x* has φ and to infer in part therefrom that *S* uttered intending *A* to believe *p*. Making this explicit yields the following slightly tweaked version of Grice's account of assertoric speaker-meaning:

> For any person *S*, proposition *p*, and utterance *x*, *S* meant *p* in uttering *x* iff for some feature φ and person *A*, *S* uttered *x* intending
>
> (1) *x* to have φ;
> (2) *A* to recognize that *x* has φ;
> (3) *A*'s recognition that *x* has φ to function as at least part of *A*'s reason for believing that *S* uttered *x* intending:
> (4) *A* to believe *p*;
> (5) *A*'s recognition of *S*'s intending *A* to believe *p* to function as at least part of *A*'s reason for believing *p*.

Let's call the value of 'φ' in an act of speaker-meaning its *inference-base feature* (its *IB-feature*, for short). Acts of speaker-meaning are typically performed by uttering sentences of a language common to the speaker and her audience, and the IB-features of those sentences are their meanings. If you utter 'It's snowing' to communicate that it's snowing, the IB-feature of the sentence 'It's snowing' on which you rely is the meaning of that sentence in English. The reason IB-features are typically meaning properties is that meaning properties are optimal IB-features: if you want to tell your child that it's snowing, you would do much better to utter 'It's snowing' than to attempt to communicate that it's snowing by impersonating a snow flake or uttering 'The flamingoes are flying south early this year.' At the same time, a *sine qua non* of a Gricean account of speaker-meaning is that the only intentional notions mentioned on its right-hand side are ordinary propositional-attitude notions, and, consequently, it's not a necessary condition for a person's meaning a proposition that what she utters have a semantic property as its IB-feature. For example, during a lecture one might communicate to one's friend that one is bored by closing one's eyes and pretending to snore. The invisible hand in the displayed account of speaker-meaning is that in any population whose members have frequent need to communicate with one another, the fact that they frequently communicate with one another will result in their utterances having IB-features that are both optimal and specifiable wholly in terms of what they know their speaker-meaning practices to be. The invisible-hand idea is that, since the notion of speaker-meaning utilized in these optimal IB-features is defined in wholly non-semantic terms, these features will also be intrinsically specifiable in wholly non-semantic terms. The Gricean invisible-hand strategy is completed by *identifying* meaning properties with those non-semantically specifiable optimal IB-features, thereby explaining the optimality of meaning properties as IB-features.

The Gricean account of assertoric speaker-meaning requires one further tweak before we have an account of assertoric speaker-meaning that best reveals the Gricean strategy for explaining expression-meaning in terms of the conditions that define speaker-meaning. Earlier (see §1) I mentioned the notion of *common knowledge* Lewis introduced in *Convention* and the similar notion of *mutual knowledge* that I introduced in *Meaning*. The further tweak is that mutual (or common) knowledge must be added to the Gricean mix to yield this account of speaker-meaning:

> [SM] For any person *S*, proposition *p*, and utterance *x*, *S* meant *p* in uttering *x* iff for some feature φ and person *A*, *S* uttered *x* intending it to be mutual knowledge between *S* and *A* that *x* has φ and, at least partly on that basis, mutual knowledge that *S* uttered *x* intending *A* to believe *p* and intending their mutual knowledge that *S* uttered *x* intending *A* to believe *p* to be at least part of *A*'s reason for believing *p*.

Mutual knowledge was originally introduced to repair the failure of Grice's original conditions to provide a set of jointly sufficient conditions for speaker-meaning (see, e.g., Schiffer, 1972, II.1 and 2); I invoke it now because of the way it will be needed in the Gricean attempt to define expression-meaning in terms of speaker-meaning. There are better and worse ways to understand mutual knowledge, and I might not have opted for the best way in my book. The essential job mutual knowledge needs to perform is to capture the sense in which acts of communication require the defining features of speaker-meaning to be "out in the open" between speaker and hearer. In *Meaning* I offered a set of finite conditions for generating mutual knowledge, and I now think that I would have done best simply to have identified mutual knowledge with a version of those base conditions. In any case, for present

purposes I'll continue to use 'mutual knowledge' and its cognates as dummy expressions for whatever turns out to be the best accommodation of the requisite out-in-the-openness.

The Gricean takes his invisible-hand strategy to be most clearly and paradigmatically exhibited in his account of simple signals,[10] and a little thought experiment will show how that is supposed to work. There is a weekly seminar regularly attended by the same people. Their practice is to raise their hands if they want to be called on, but, while they would benefit from one, they have no simple way of indicating that what they want to contribute is a follow-up question. During one session, a visitor from the University of Latvia, Zuzka, raises her hand during a lively discussion and moves her index finger rapidly up and down. It's clear to all that Zuzka intends to communicate something by this gesture, but at first no one can figure out what it is. After several minutes it somehow transpires that in Latvian universities that sort of finger movement means that one has a follow-up question. Now suppose that during another exchange the following week one of the attendees, Harvey, raises his hand and moves his index finger rapidly up and down. In this case, everyone in the class will know straightway that Harvey means that he has a follow-up question. What explains this dramatic difference? Why was it that no one knew what Zuzka meant in moving her finger in way **Ω**, whereas one week later the very same people effortlessly and immediately knew that in moving his finger in way **Ω** Harvey meant that he had a follow-up question? The answer, of course, is that at the time Zuzka performed the finger movement it had no feature that was an effective IB-feature in the seminar for meaning that one had a follow-up question, but after that the movement had a few features it didn't previously have, and these features separately and together constituted quite an effective IB-feature for meaning that one had a follow-up question. One of these features was that of being mutually known to be such that it was performed by Zuzka in her attempt to communicate to the seminar that she had a follow-up question; another was that of being mutually known to be the standard way in Latvian universities to communicate *that one had a follow-up question* (*Q*, for short). Since it benefited the seminar to have a simple way to indicate that one had a follow-up question, now that no one doubts what one would mean by moving one's index finger in way **Ω**, it's apt to catch on, so that it soon becomes mutual knowledge in the seminar that there is a practice of meaning *Q* by moving one's index finger in way **Ω**, and that mutual knowledge makes the gesture an optimal IB-feature as regards meaning *Q* in the seminar.

You may recognize that we have entered the territory of the kind of self-perpetuating regularities that David Lewis showed to be conventions, and at this point it seems correct to say that the gesture means *Q* in the seminar. Now the gesture **Ω** doesn't mean a proposition, since each person who makes the gesture will mean that *she* has a follow-up question. But to keep what is essential to the lines we are exploring from being hidden in complexities and qualifications we are ignoring non-assertoric speech acts, indexicality, and ambiguity, and pretending that sentence-size meanings are propositions. Relative to all that, the Zuzka example suggests an account of simple-signal meaning that entails the following:

[SIMP] For any *x*, proposition *q*, and population *P*, *x* is a simple signal that means *q* in *P* iff it's mutual knowledge in *P* that there is a practice in *P* of meaning *q* by uttering *x* and intending that mutual knowledge to function as *x*'s IB-feature when a member of *P* means *q* by uttering *x*.

Practices that satisfy SIMP are conventional practices (see Schiffer (1972, V.3), but it may not be easy to describe them as conventions. At least SIMP doesn't require there to be a

convention in P to mean q by uttering x, which is good, since x can mean q in P even though members of P have ways other than uttering x to mean q, nor does it require there to be a convention in P not to utter x unless one thereby means q, which is also a good thing, for even if x means q in P members of P might communicate other propositions by, for example, using x metaphorically. In any case, whether or not the practice entailed by SIMP can be described as a convention, as opposed to a conventional practice, that wouldn't give us reason to suppose SIMP fails to provide either a necessary or a sufficient condition for simple-signal meaning.

The Gricean sees an even broader application for the kind of IB-feature employed in SIMP. Recall that for the Gricean speaker-reference is to be defined in terms of speaker-meaning, and this will be so in a way that suggests that the name-of relation is best captured by something along the lines of:

> [*N*] *n* is a name of *y* in *P* iff it's mutual knowledge in *P* that there is a practice in *P* of speakers' referring to *y* with *n* & intending that mutual knowledge to be *n*'s IB-feature.[11]

In other words, when you say to me 'Saul Kripke is giving a talk today' you intend the feature of 'Saul Kripke' that enables me to know that you are referring to Saul Kripke to be that it's mutual knowledge in a population to which we both belong that there is a practice of referring to Kripke with 'Saul Kripke,' which for the Gricean is roughly equivalent to saying that what enables me to know that you are referring to Kripke with 'Saul Kripke' is that it's mutual knowledge between us that 'Saul Kripke' is the name of Saul Kripke in a population to which we both belong.

Of course, the Gricean can't hope to account for the meanings of natural language sentences in a similar way, since a sentence has its meaning even if no one has ever uttered it. How, then, might the Gricean invisible-hand strategy apply to natural languages? The Gricean expects that if σ means q in the language L of a population P then, while there needn't be any practice in P of uttering σ, there will prevail in P a set of practices pertaining to L such that one utters σ in conformity with those practices only if one means q in uttering σ. The question is, what might those practices be? Unfortunately for the Gricean, we are already positioned to see that his goal of defining expression-meaning in terms of his defined notion of speaker-meaning is an impossible goal for him to achieve. The invisible-hand strategy fails to take one to any good place. We can appreciate this in the following way.

SIMP, the lately displayed Gricean definition of simple-signal meaning, is apt to seem plausible. The only semantic notion used in SIMP is the notion of speaker-meaning, and SM, which I'm taking to represent the Gricean account of speaker-meaning, has been defined in terms of non-semantic propositional attitudes. It may therefore seem that, if both SIMP and SM are correct, then the Gricean has succeeded in defining simple-signal meaning in wholly non-semantic terms, and thereby at least to have shown that the intentionality of simple signals derives from the intentionality of the propositional attitudes in terms of which it's defined. *Not so!* Even if SIMP and SM are correct, that would not entail that simple-signal meaning had been indirectly defined in terms that included those that define speaker-meaning. The point is familiar and simple. Suppose that

$$A =_{\text{def}} \ldots X \ldots Y \ldots$$

and that

$$B =_{\text{def}} \ldots \boldsymbol{A} \ldots Z \ldots$$

then

$$B =_{\text{def}} \ldots X \ldots Y \ldots Z \ldots$$

does *not* follow *if the context of 'A' in 'B =$_{def}$ … **A** … Z …' is intentional*. Specifications of knowledge are intentional contexts *par excellence*, and *speaker-meaning is mentioned in SIMP only in specifying the mutual knowledge required for simple-signal meaning*. Consequently, we have no reason to expect that if SIMP is correct, then SIMP$_G$, the result of replacing every speaker-meaning expression in SIMP with what SM provides as its definitional expansion, will also be correct. That it would be wrong to expect SIMP$_G$ to be true if SIMP is true would seem to be confirmed by a side-by-side comparison of the two definitions:

SIMP	**SIMP$_G$**
For any *x*, proposition *q*, and population *P*, *x* is a simple signal that means *q* in *P* iff it's mutual knowledge in *P* that there is a practice in *P* of meaning *q* by uttering *x* and intending that mutual knowledge to function as *x*'s IB-feature when a member of *P* means *q* by uttering x.	For any *x*, proposition *q*, and population *P*, *x* is a simple signal that means *q* in *P* iff it's mutual knowledge in *P* that there is a practice in *P* whereby a member *S* of *P* utters *x* in order that there be something *y* that *S* utters such that, for some feature φ and member *A* of *P*, *S* utters *y* intending it to be mutual knowledge between *A* and *S* that *y* has φ and, at least partly on that basis, mutual knowledge that *S* uttered *y* intending *A* to believe *q* and further intending their mutual knowledge that *S* uttered *y* intending *A* to believe *q* to be at least part of *A*'s reason for believing *q*, and in such utterances of *x S* intends the inference-base feature φ of *x* to be the fact that it's mutual knowledge in *P* that there is a practice in *P* whereby a member *S* of *P* utters *x* in order that there be something *y* that *S* utters such that, for some feature φ and member *A* of *P*, *S* utters *y* intending it to be mutual knowledge between *A* and *S* that *y* has φ and, at least partly on that basis, mutual knowledge that *S* uttered *y* intending *A* to believe *q* and further intending their mutual knowledge that *S* uttered *y* intending *A* to believe *q*.

SIMP is apt to seem plausible, SIMP$_G$ quite implausible, which isn't surprising, given that we have no reason at all to expect the two definitions to have the same truth-value even if SIMP and SM are both true.[12]

The Gricean invisible-hand strategy for defining the semantic properties of expressions in non-semantic terms never gets off the ground: the Gricean simply has no way of defining expression-meaning in terms of the *intentions* that by his lights are constitutive of

speaker-meaning. But that doesn't preclude defining expression-meaning in terms of the *concept* of speaker-meaning, and that suggests the possibility of a convention-based way of reducing the semantic to the psychological that isn't strictly Gricean *intention*-based semantics but might be considered a cousin of it and, if correct, would show how the intentionality of language derives from the intentionality of thought. The next section explores this idea.

3 An Almost-Gricean Semantics

For all we yet know, SIMP, which defines simple-signal meaning in terms of a certain kind of conventional speaker-meaning practice, remains plausible. All that was shown was that the attempt to replace the speaker-meaning expressions in SIMP with their Gricean expansions results in an implausible account of simple-signal meaning, even if the Gricean account of speaker-meaning is correct. One familiar diagnosis of this substitutivity failure which derives from Frege is that when an expression occurs in an intentional context, as when it's used to specify what someone knows, the expression doesn't denote the object, property, or relation it denotes when it occurs in extensional contexts, but denotes instead a *concept* of what it denotes in those extensional contexts. The idea, in other words, is that the occurrence of 'means' in the sentence 'In making that gesture Zuzka meant that she had a follow-up question' denotes the speaker-meaning relation, but its occurrence in an intentional context, such as the context created by 'knows' in 'Sid knows that in making that gesture Zuzka meant that she had a follow-up question,' denotes a *concept* of that relation and not the relation itself. Suppose that, or something enough like it, is right. Then we would have defined simple-signal meaning not, as the Gricean would have it, in terms of the intentions that define speaker-meaning, but rather in terms of what, for all we yet knew, was a primitive concept of speaker-meaning (see Schiffer, 1987, §9.3). But *if* (i) that concept of speaker-meaning could be identified with a psychological construct that was itself definable in non-intentional terms – say, in terms of the inferential and causal roles of neural expressions in mentalese, (ii) the speaker-meaning relation it denoted was definable without recourse to any intentionality other than the intentionality of non-semantic propositional attitudes, and (iii) we can move beyond SIMP to give an account of the semantic properties of all expressions in terms of conventional practices whose specification involved that concept of speaker-meaning, *then* we could achieve something like a reduction of the semantic to the psychological. And if, further, the speaker-meaning relation denoted by the concept of speaker-meaning was definable *à la* Grice and meaning properties could still be conceived as IB-properties, then – what the hell – we would have a theory that was close enough to Gricean semantics to be called an almost-Gricean semantics.

To see whether that can be done, a good place to begin would be to assume that SIMP, the account of simple-signal meaning, was correct and try to see whether speaker-meaning conventions (or conventional practices) might fare better than conventions of truthfulness in a definition of the public-language relation. We are encouraged to think that might be so by the problem with which we left Lewis's proposal that

> For any Lewis-language *L* and population *P*, *L* is a public language of *P* iff there prevails in *P* a convention of truthfulness in *L*, sustained by an interest in communication.

This was the problem that virtually every convention – for example, a convention to drive on the right or to wear casual clothes to work on Fridays – was for Lewis a convention of truthfulness in a "language" that was in no sense used as a medium of communication,

not even when the convention was somehow or other "sustained by an interest in communication." The encouragement this problem gave to a Gricean approach was that it suggested that in order for *L* to count as a public language of *P* the convention (or conventional practice) governing the use of *L* should be a convention conformity to which requires uttering sentences of *L* in order to mean what those sentences mean* in *L*. In pursuing this line of thought, however, it's important to keep in mind that, while a correct definition of the public-language relation would *eo ipso* be an account of what it was for a sentence to have meaning in a population, that would be no stopping point even for almost-Griceans unless the account of the public-language relation, unlike those Lewis had on offer, somehow or other managed also to define what it was for an expression of *any* syntactic kind – words and phrases, as well as sentences – to have meaning in a population.

The most obvious Gricean counterpart to Lewis's notion of a convention of truthfulness would be a convention of meaning, where that is taken to mean that there prevails in *P* a convention not to utter any sentence σ of *L* unless, for some *q*, $L(\sigma) = q$ and in uttering σ one means *q*, and where that in turn entails mutual knowledge which, when understood *in sensu diviso*,[13] comes to:

(A) For any Lewis-language *L* and population *P*, *L* is a public language of *P* iff for any σ, *q*, if $L(\sigma) = q$, then it's mutual knowledge in *P*
  (1) that a member of *P* won't produce an unembedded utterance of σ unless she means *q* thereby;[14]
  (2) that if a member of *P* means *q* in uttering σ, then she intends σ's IB-feature to be the fact that it's mutual knowledge in *P* that (1).

(A) has more than a few problems, the most worrisome of which are, first, that it suffers from the same meaning-without-use problem that (A)'s counterpart in Lewis was seen to suffer from and, second, that it doesn't explain what it is for a word or other sub-sentential expression to have meaning in a population. Brian Loar did as much as any Gricean to understand expression-meaning in Gricean terms, and he offered an account of the public-language relation that both took into account the problems that arose for Lewis's account and provided an account of what it is for an expression of any syntactic kind to have meaning in a population (Loar, 1976). Taking our cue from Loar, and ignoring some fixable problems, we need to take three more steps to achieve what by Loar's lights would be a correct account of the public-language relation (relative to our ongoing simplifications about ambiguity, vagueness, indexicality, non-indicative moods, and every sentence having a proposition as its meaning).

The first step is to counterfactualize the mutual knowledge in (A), thereby getting:

(B) For any Lewis-language *L* and population *P*, *L* is a public language of *P* iff for any σ, *q*, if $L(\sigma) = q$, then it's mutual knowledge in *P*
  (1) that if a member of *P* were to produce an unembedded utterance of σ she would mean *q* thereby;
  (2) that if a member of *P* means *q* in uttering σ, then she intends σ's IB-feature to be the fact that it's mutual knowledge in *P* that (1).

The problem with (B), as Loar noticed, is one already encountered in our discussion of Lewis: it requires speakers of a language to know the meaning of every sentence of their

language, whereas we already know that there are infinitely many sentences of every spoken language that are too long or convoluted for ordinary speakers to understand. The fix Loar proposes, which takes us to the second step, restricts the mutual knowledge to those sentences of their language members of a population can understand:

(C) For any Lewis-language *L* and population *P*, *L* is a public language of *P* iff *there is a large enough restriction L′ of L* such that, for any σ, *q*, if $L'(\sigma) = q$, then it's mutual knowledge in *P*
  (1) that if a member of *P* were to produce an unembedded utterance of σ she would mean *q* thereby;
  (2) that if a member of *P* means *q* in uttering σ, then she intends σ's IB-feature to be the fact that it's mutual knowledge in *P* that (1).

Loar knew that (C) was no stopping point, for it has the same meaning-without-use problem that Lewis's definition of the public-language relation has: infinitely many languages that aren't public languages of any population will each entail the restriction *L′* before differing wildly from one another beyond what they have in common; and, of course, it doesn't explain what constitutes a word's having meaning in a population.

The languages we are trying to capture are finitely specifiable. A finite specification of a language is a grammar. In *Convention*, Lewis argued that, if the infinite language *L* is the language of *P*, then *L* must be finitely specifiable, but there will be no fact of the matter as to which finite specification of *L* is the correct specification of *L*. Lewis reverses himself in (1992). There he comes to the realization that in order to determine which language is a population's public language it must be possible to determine which grammar generates that language, but he now thinks he knows how this can be done:

> True, there are many grammars. But they are not on equal terms. Some are "straight" grammars; for example, any grammar that any linguist would actually propose. Others are "bent," or "gruesome," grammars; for example, what you get by starting with a straight grammar for English and adding one extra rule, which states that every expression with more than forty occurrences of the word 'cabbage' is a sentence meaning that God is great. We have no difficulty in telling the difference …. We can reasonably hope that all straight grammars that agree on the used fragment will agree everywhere. (Lewis, 1992, p. 110)

The application of this solution to (C) yields:

(D) For any Lewis-language *L* and population *P*, *L* is a public language of *P* iff there is a large enough restriction *L′* of *L* and a grammar Γ such that (a) Γ is the "straightest" grammar that determines *L′*, (b) Γ determines *L*, and (c) for any σ, *q*, if $L'(\sigma) = q$, then it's mutual knowledge in *P*
  (1) that if a member of *P* were to produce an unembedded utterance of σ she would mean *q* thereby;
  (2) that if a member of *P* means *q* in uttering σ, then she intends σ's IB-feature to be the fact that it's mutual knowledge in *P* that (1).

A striking feature of this solution to the meaning-without-use problem is that it doesn't require the grammar that determines a person's language to play any role in the psycholinguistic explanation of the information processing that underlies, and thus accounts for, the

person's ability to understand utterances in that language. The striking fact invites an objection to the solution, which I raised when Lewis and I discussed a version of his (1992) in 1990 – namely, that if we learned that the internally represented grammar implicated in the explanation of a person's ability to understand novel sentences was in fact a bent grammar that determined a language $L^{\#}$, then we should want to say that $L^{\#}$ was her language, even if the only straight grammar that fit the used fragment determined a different language. Lewis was unmoved:

> Maybe there is a grammar somehow written into the brain. And conceivably it is a bent grammar, so that the language it generates differs, somewhere outside the used fragment, from the language we get by straight extrapolation. Schiffer has asked: does straight extrapolation give the right answers even then? I think so. If not, then whenever we resort to extrapolation to answer questions of syntax and semantics, we are engaged in risky speculation about the secret workings of the brain. That seems wrong. (Lewis, 1992, p. 110, n. 6)

Risky speculation about the secret workings of the brain is certainly to be avoided, but, as we'll presently see, it's not entailed by the hypothesis that the criterion for being a population's language is that it's determined by the grammar that explains how members of the population are able to understand the utterances they hear. For suppose that the infinite language L is in fact the public language of population P. Let L' be the fragment of L that has been or might be produced in P. We may assume that each member of P has a compositional understanding of L', one that relies on the only straight grammar to fit L' and the only grammar that both fits L' and determines L. We should certainly insist that L is the language of P. Now it's possible for there to be another population $P^{\star}$ such that L' is also the fragment of their language that has been or might be produced in $P^{\star}$, but with this difference: each sentence of L' is for them a *non-composite* utterance type. In other words, each sentence of L' is for them as a simple signal, such as a fire alarm, is for us: it has propositional meaning, but its meaning is not in any way determined by semantic features of its parts and structure. The "language" L' is simply a large finite set of simple signals; the members of $P^{\star}$ have prodigious memories, and they have learned the sentences of L' the only way they could learn them – namely, one by one. They know what their sentences mean because they have learned what each one means as a single fact, and they have no way of computing what a sentence means on the basis of their knowledge of its syntax and the meanings of its parts, as, from their perspective, a sentence no more has a syntax and semantically relevant parts than a fire alarm has for us. Consequently, members of $P^{\star}$ have no way of understanding a sentence that belongs to L but not to L'; they have no way, in fact, of determining the meaning of any novel sentence. Clearly, the infinite language L is *not* used in $P^{\star}$. Yet every straight grammar that generates L', the language that *is* used by them, is a grammar of L. There are also counter-examples to the straight-grammar solution involving infinite languages. Suppose, for example, that the members of a secret society make up a language whose syntax and semantics they actually write down and formally adopt under a Mafia-like oath, and that, for some reason, perverse or not, the grammar they adopt is by their explicit design a bent grammar. Let's also suppose that an internal representation of the bent grammar plays an essential role in their processing of utterances in their invented language. I would think that the language of the society is the one their bent grammar describes, whether or not

there is a straight grammar that fits the sentences the members of the society actually produce or are likely to produce.

Brian Loar has suggested that appealing to a grammar that is somehow written into the brain is exactly what must be done both to solve the meaning-without-use problem and to achieve an account not just of a sentence's meaning in a population but of every expression's meaning in a population. He first stipulates that "*L* is grounded in *P*, with regard to its restriction *L′*, just in case those correlations of sentential features and meaning contributions which figure in the correct psychological explanation of the continuing mastery of *L′* (i.e. effective *L*) by members of *P* will generate, when extended, the full language *L*, including its incomprehensibly complex sentences" (Loar, 1976, pp. 159–160). This would yield:

(E) For any Lewis-language *L* and population *P*, *L* is a public language of *P* iff there is a large enough restriction *L′* of *L* such that, for any σ, *q*, if *L′*(σ) = *q*, then (a) it's mutual knowledge in *P*
  (1) that if a member of *P* were to produce an unembedded utterance of σ she would mean *q* thereby;
  (2) that if a member of *P* means *q* in uttering σ, then she intends σ's IB-feature to be the fact that it's mutual knowledge in *P* that (1)
  and (b) *L* is grounded in *P* with regard to *L′*.

But what about Lewis's objection that if the grammar that determines the used language is the one written into the brain, then "whenever we resort to extrapolation to answer questions of syntax and semantics, we are engaged in risky speculation about the secret workings of the brain"? Well, suppose I believe that the correct grammar for my language is whatever grammar is written into the brains of those of us who use the language. It would be no small feat to construct a grammar that merely fits the fragment of my language that has been or is ever likely to be used, but suppose that, after considerable labor, experts come up with a grammar Γ that gets the fragment right. Γ will determine not just the fragment in question but an entire infinite language: it assigns a syntactic, semantic, and phonological interpretation to each of infinitely many sentences, all but a small minority of which have no chance of ever being used by me or anyone else. It seems a very good bet that Γ is a straight grammar, probably the only straight grammar anyone can come up with that fits the used fragment. So now I must decide: Is Γ the grammar implicated in my language processing, or is that grammar one that coincides with Γ on the used fragment but differs from it in that it interprets every sentence containing 40 or more occurrences of 'cabbage' as meaning that God is great? I will of course go with the straight grammar Γ, but not on the basis of a risky speculation. My going with the straight grammar Γ is a risky speculation about the secret working of the brain only if the scientist who infers a straight theory from the evidence that underdetermines it, rather than one of the infinitely many bent theories that fits the same evidence, isn't making a risky speculation about the infinitely many possible unexamined cases her theory must cover.

Nevertheless, there is a serious problem with (E) or any other almost-Gricean account of the public-language relation which avoids the meaning-without-use problem by appeal to the grammar implicated in the explanation of our language processing. The problem is that if, like Loar, one invokes groundedness in one's account of the public-language relation – that is to say, into one's account of what determines an expression to have meaning in a population – then one is invoking something that in

effect makes the rest of one's account superfluous. For if one is invoking groundedness, then one needs nothing more than:

(F) For any Lewis-language *L* and population *P*, *L* is a public language of *P* iff (1) members of *P* regularly communicate with one another by uttering sentences of *L* and meaning thereby what those sentences mean* in *L*, and (2) for some grammar Γ of *L*, their ability to know what members of *P* mean in uttering those sentences is grounded in Γ.[15]

(F) is neither Gricean nor convention-based; it uses the notion of speaker-meaning, but relies on no *particular* account of it, Gricean or otherwise. I'm not suggesting that (F) is correct. My point is merely that it would appear that in order for an almost-Gricean convention-based theorist to have an account of the public-language relation (= an account of expression-meaning) she will in effect need Loar's notion of groundedness, which entails the right-hand side of (F), and that by anyone's lights should already be a necessary and sufficient condition for a Lewis-language's being a public language of a population.[16]

4 What Endures?

In this chapter I have looked critically at two programs that should dominate any curriculum bearing the label "Intention and Convention in the Theory of Meaning": David Lewis's convention-based account of sentence meaning and the more comprehensive Grice-inspired program of intention-based semantics. As for Lewis, one may object to his account of convention (see, e.g., Gilbert, 1981) and one may deny that the languages we speak can be represented as Lewis-languages (Lewis, 1975, p. 180), but we have seen that even if Lewis's account of convention is correct and the languages we speak can be represented as Lewis-languages, no convention or conventional practice – whether of truthfulness or of speaker-meaning – can explicate what it is for an expression to have meaning for a person or population of persons.

The more ambitious IBS also fails in its attempt to explain expression-meaning. First, it simply doesn't follow that if one can define expression-meaning in terms of speaker-meaning and speaker-meaning in terms of intentions that one can thereby define expression-meaning in terms of intentions. That would follow only if mention of speaker-meaning in the analysis of expression-meaning occurred in a non-intentional context, whereas its occurrence is in a specification of the mutual knowledge the account requires, a paradigm intentional context. Second, as we saw in our discussion of almost-Gricean IBS, an expression's meaning in a population can't be defined in terms of the speaker-meaning practices that prevail in the population. What of the possibility of a Gricean account of speaker-meaning? True, the limitations we now see on the work it could do considerably diminish the interest in having such an account, but nothing has been said so far in this chapter to show that no such account can be correct. And while such an account couldn't be used to explicate expression-meaning, it's not unreasonable to suppose it would have relevance to speech-act theory and to issues about the semantics/pragmatics interface, especially since Grice is nowadays best known for his theory of implicature, and for Grice (nearly enough)

S implicates p in uttering σ iff in uttering σ *S* means but doesn't say *p*,

where in Grice's quasi-technical sense of 'say,'

S said p in uttering *σ* iff *p* "fits" the meaning of σ and *S* meant *p* in uttering σ,

where "fitting" is exemplified in, say, the way the proposition *that Betty is ready to take the exam* fits the meaning of 'She is ready.' And there remains the unsettled question of whether semantic intentionality can be reduced to the intentionality of mental states.

There are reasons to doubt that a Gricean account of speaker-meaning can be achieved. First, it's not even clear what an account of "speaker-meaning" is supposed to be an account of when it's not constrained by the need to be the speech-act notion needed to define expression-meaning.[17] Grice's "Meaning" (and, ahem, my own *Meaning*, as well as other early work in Gricean semantics, such as Jonathan Bennett's (1976) *Linguistic Behaviour*) gives the impression that the target notion of speaker-meaning is the concept expressed by the ordinary language use of sentences of the form 'In uttering *x S* meant that such and such.' However, an attentive reading of Grice (or any other Gricean) reveals that that can't exactly be what is at issue. For example, Gricean accounts of speaker-meaning would approve the form of such speaker-meaning reports as:

(1) In uttering 'Is Frankfort the capital of Kentucky?' *S* meant *that you were to tell her if Frankfort was the capital of Kentucky*.
(2) In uttering 'Move to Frankfort, Kentucky!' *S* meant *that you were to move to Frankfort, Kentucky*.

Yet such reports are not likely to be found in ordinary speech. A speaker who uttered 'Is Frankfort the capital of Kentucky?' or 'Move to Frankfort, Kentucky!' would be said to have meant something, but if asked what the speaker meant, no ordinary speaker would answer with (1) or (2). Rather than respond with (1) and (2) she would be much more likely to respond, respectively, with 'He asked if Frankfort was the capital of Kentucky' and 'He told you to move Frankfort, Kentucky.' This doesn't mean that the Gricean is wrong to use sentences like (1) and (2) as canonical forms for reporting what speakers *mean* when they perform interrogative or imperatival speech acts, but it does seem to show that in using those representations he is stipulating a technical use of the verb 'to mean.' But then it's not clear what technical notion is being introduced. The Gricean's benchmark meaning reports are those he uses to report assertoric acts of speaker-meaning, such as 'In uttering "Il pleut" Pierre meant that it was raining in Paris.' In such reports the 'that'-clause is taken to refer to what the speaker meant, which is taken to be a proposition of some stripe or other. This suggests that the Gricean takes assertoric speaker-meaning to be a relation between speakers and propositions of some yet unspecified kind. At the same time, while the 'that'-clauses in (1) and (2) are being used to specify what the speaker meant, they can't be referring to propositions, nor, I should think, to anything else. One is left to wonder what univocal notion the Gricean takes speaker-meaning to be. Self-described Griceans today, such as Stephen Neale (see, e.g., Neale, 1992), are unconcerned that no Gricean analysis of speaker-meaning is recognized even by Griceans as being correct. Their commitment seems to be to the idea that what *S* means in uttering a sentence σ is determined entirely by intentions she has in uttering σ, where those intentions are intrinsically specifiable in non-semantic terms, and where the sentence uttered serves only as the means by which *S* intends those intentions to be recognized. I doubt that that idea can be correct. When Jack utters 'What's the capital of Kentucky?' his *intention* is to *ask* Jill what the capital of Kentucky is, and when Jill responds, 'Frankfort is the capital of Kentucky,' her intention is to *tell* Jack that Frankfort is the capital of Kentucky. I doubt that if we subtract those semantic intentions from all the intentions Jack and Jill had in

producing their utterances that there would be enough left over to entail that they performed the speech acts they in fact performed (Schiffer, 1987, ch. 9).

Other concerns emanate from *vagueness*. I think one salubrious effect of Gricean work on meaning is a better appreciation of the role of a speaker's intentions in the determination of what she meant and of what references she made, especially as such intentions may be crucial to the semantics of indexicals and other referring expressions. At the same time, I think certain features of vagueness show that the extent to which intentions determine what a speaker meant or referred to is quite limited. A single example should make clear what I have in mind. Jane is speaking on the phone with a friend in Los Angeles, and at one point she remarks, 'It's raining here.' Let's suppose that Jane made her remark while standing under an umbrella in pouring rain. Then her utterance is determinately true, and she clearly meant *something* in making her utterance. But *what* did she mean and what *determines* whatever it is that she meant? Well, what she meant is partly determined by the reference of her utterance of 'here,' so to what location did her utterance of 'here' refer? How one answers that question will depend on one's views about vagueness. The epistemic theorist of vagueness will say that there is some absolutely precise region of space α to which Jane's utterance of 'here' referred. If this is correct, then it should be obvious that that reference wasn't determined by Jane's referential intentions, since, having no way to distinguish α from the uncountably many precise regions with which it overlapped, she could not have intended to refer to α. The supervaluationist will say that there is no location that is determinately the referent of her utterance, but there are myriad – indeed, uncountably many – locations each of which is such that it's indeterminate whether it's the referent, or indeterminate whether it's indeterminate whether it's the referent, and so on (he will say that Jane's utterance is true because it's true in each of those "precisifications"). Suppose α is one of the uncountably many precise locations each of which is such that it's indeterminate whether it's the referent of Jane's utterance of 'here.' Then a theorist who wants to say that a speaker's referential intentions determine the reference of the indexicals she utters will want to say that it's indeterminate whether Jane intended to refer to α with her utterance of 'here.' But it should be obvious that she determinately did *not* intend to refer to α with her utterance of 'here' (cf. Buchanan and Ostertag, 2005, and Buchanan, 2010). How could she, when she couldn't pick out α from the billions of minutely differing overlapping areas if her life depended on it? A theorist who thinks that vagueness isn't confined to words and concepts might want to say that a certain vague area is the referent of Jane's utterance of 'here.' But if α is the vague area to which Jane's utterance of 'here' referred, Jane will be wholly ignorant of that fact: just ask her to tell you which locations are borderline – or borderline borderline, and so on – cases of being included in α. Of course, what goes for 'here' in Jane's utterance goes also, *mutatis mutandis*, for what she meant in uttering 'It's raining here.' The rub for intention-based semantics is that what goes for Jane's utterance goes also for virtually *every* utterance; for virtually every sentence uttered is to some extent vague.

What of the view that we must "explicate the intentional characteristics of language by reference to believing and to other psychological attitudes" (Chisholm, 1958, cited in Speaks, 2010), which seemed to motivate much of the work in IBS and arguably in Lewis's convention-based semantics.[18] It's difficult to say in the absence of a clear and plausible account of how exactly the intentionality of language derives from the intentionality of thought, and, most important, it's difficult to see why we should care whether the view is correct when what is apt to seem to be most important is that the intentionality of thought and language should supervene on non-intentional facts. At one time Brian Loar and

I thought it important to *identify* intentional facts with facts that are intrinsically specifiable in non-intentional terms, and we thought that to get such a reduction it was important first to reduce semantics to psychology, so that one could then reduce psychology to physical and functional facts in ways that seemed somewhat promising in the 1970s (see, e.g., Loar, 1981, and Schiffer, 1982). Alas, those ways no longer seem plausible (see Schiffer, 1987), not to mention that we no longer seem to have IBS at hand to reduce the semantic to the psychological.

Notes

1 Actually, I called the notion mutual knowledge* to make clear that I was stipulatively defining a technical notion, rather than trying to define a notion that was already called 'mutual knowledge' in the vernacular. It's not surprising Lewis and I independently hit on essentially the same notion, since we each invoked the notion to preclude essentially the same kind of counter-example, although for Lewis the counter-example he needed to prevent was to the account of convention he was developing, whereas the counter-example I needed to prevent was to the Gricean account of speaker-meaning I was trying to repair.

2 The generality *in sensu composito/diviso* distinction is from Abelard (Lewis, 1969, p. 64); those familiar with the knowledge *de dicto*/*de re* distinction will recognize that Abelard's distinction is definable in terms of that distinction.

3 There is a third problem I feel compelled to mention although I can't hope to develop it here (I do try to develop it in "How vagueness affects meaning," an unpublished manuscript that is still a work in progress). The problem is that a language can't be described as a pairing of sounds and meanings unless there are such things as meanings – that is to say, unless an expression's having meaning consists in there being some thing that it means. It is my view that that isn't what having meaning consists in.

4 Lewis (1975, p. 187) gives a pithy restatement of the problem: "A sentence never uttered at all is *a fortiori* never uttered untruthfully. So truthfulness-as-usual in [English] plus truthfulness-by-silence on the garbage sentences constitutes a kind of truthfulness in [Gobbledygook] … Therefore we have a prevailing regularity of truthfulness … in [Gobbledygook]. This regularity qualifies as a convention in *P* …."

5 Pinker (1994). Pinker attributes the example to Annie Senghas.

6 The notion of an illocutionary act – certain acts we perform in uttering sentences, such as telling, asking, requesting, ordering, warning, and so on – is due to Austin (1962).

7 For attempts to define illocutionary acts in terms of a Gricean notion of speaker-meaning, see Strawson (1964) and Schiffer (1972, ch. 4). For an attempt to define speaker-reference in terms of Gricean speaker-meaning, see Schiffer (1978; 1981).

8 Grice (1957, p. 385). Grice uses 'utterance' and its cognates in a technical sense that includes non-linguistic items and behavior.

9 There is an obvious problem for the Gricean account of assertoric speaker-meaning given that this is how recognition of intention is supposed to result in *A*'s believing the proposition *S* uttered *x* intending *A* to believe – namely, that while (3) might be a necessary condition for *S*'s *telling A p*, it's not a necessary condition for *S*'s *meaning p*; for if it were a necessary condition, then Grice would not have meant anything in writing any of the sentences in "Meaning," and this because, while Grice produced those sentences intending us to believe what they expressed, he certainly did not intend his readers to believe what he wrote on his authority; that is to say, he didn't intend his readers to believe anything he said because Grice's believing it was good evidence of its truth.

10 Relative to ongoing simplifying assumptions, γ is *simple signal* in population *P* just in case, for some q, γ means q in *P*, but there are no constituents of γ such that γ's meaning q is a function of the meanings of those constituents.

11 Cf. the account of the name-of relation in Evans (1973), which is based on the account of simple signals in Schiffer (1972).

12 An even better demonstration of the point being made is obtained by replacing the speaker-reference expressions in *N*, the plausible-looking definition of the name-of relation, with the definition of speaker-reference in terms of speaker-meaning I offered in (1981).

13 We saw in §1 that it's essential that the knowledge of *L* be *in sensu diviso*, lest speakers of a language be required to have something they clearly don't have – to wit, knowledge of the syntactic and semantic rules of *L*. Grice's own suggestion about how to define expression-meaning falls afoul of this requirement. His suggestion, put in the terms of this chapter, is that a sentence σ means *q* in *P* just in case for any (or nearly any) member *S* of *P*, *S* has a "resultant procedure" to utter σ if *S* wants to mean *q*, where a resultant procedure for σ would be a procedure that results from the procedures *S* has for uttering the constituents and structures of σ. Now that doesn't yet require *S* to have propositional knowledge of what his procedures are; the problem arises when we ask how another member of *P*, *A*, is to know what *S* means when she utters σ, for here Grice says that this is to be accomplished via *A*'s knowledge that *S* has in her repertoire the procedure of uttering σ if she wants to mean *q*. But *S* can hardly intend *A* to know that σ has the IB-feature of *being such that S has in her repertoire the resultant procedure of uttering σ if she wants to mean q* unless she intends *A* to compute that σ has that feature via her knowledge of the procedures *S* has in her repertoire for the morphemes and structures from which σ is composed, and it's impossible to see how that is to be accomplished without knowledge of the language's semantics and syntax. It will also be noticed that Grice's claim *that a sentence σ means q for S only if S has in her repertoire the resultant procedure of uttering σ if she wants to mean q* also runs afoul of the meaning-without-use problem.

14 An occurrence of a sentence is unembedded just in case the occurrence is not within some other sentence.

15 This seems very much along the lines of what Stephen Laurence (1996) has proposed as "a Chomskian alternative to convention-based semantics."

16 Much of this paragraph and the one before it is taken from Schiffer (2006).

17 This is elaborated in Schiffer (1982).

18 Avramides (1989) argues that Gricean semantics should be divorced from this motivation.

Meaning, Use, Verification

JOHN SKORUPSKI[1]

1 Meaning as Use

1.1 Introductory

Language has been the focus of the analytic tradition in twentieth-century philosophy. A good deal of that philosophizing about language has drawn its inspiration from a simple-sounding idea: to understand a word is to know how to use it. The formulation is particularly associated with Wittgenstein. But the idea itself has had immensely wide influence. It was important in logical empiricism – the empiricism of Vienna in the 1930s – and also in ordinary language philosophy in Oxford after World War II. It can be traced to the nineteenth century: for example, one might see it as a central feature of Peirce's pragmatist conception of meaning, or as a generalization on the reflections of philosophically minded mathematicians and scientists, in the latter part of the nineteenth century, about the meaning of scientific and mathematical calculi. (Notable among many were Mach, Poincaré, and Hilbert.) From the idea that use exhausts meaning important consequences have seemed to flow: the elimination of metaphysics, the dissolution of skeptical paradoxes – the pseudo-problematic nature of certain classical philosophical questions.

However, this chapter will not trace the nineteenth- and twentieth-century sources of the idea.[2] Nor will it examine the question of its grand philosophical implications, though these possible implications are of major importance. Our task here will be simply to assess the idea itself. We shall examine how it leads to a distinctive conception of meaning which I will call the 'epistemic conception' (§§1.3–1.5). Verificationism, an influential doctrine about meaning associated with the Vienna Circle, may be presented as a special case of this conception: §§2.1–2.3 will consider what verificationism is, its difficulties, and whether there can be a non-verificationist but still epistemic conception of meaning. In §§3.1–3.2 I will argue that important insights contained in the epistemic conception can be retained even if we treat them as insights about the normative nature of concepts rather than as

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

insights about the form of language-rules. And I will consider the effect of doing this on an influential doctrine whose modern form is closely associated with the epistemic conception of meaning – the doctrine that the *a priori* is the analytic.

1.2 Meaning and Use in Wittgenstein

"Meaning is use" says that use, function in a language, *completely* exhausts meaning. To understand an expression or sentence is to master its use within a grammatically structured means of communicating, that is, a language. No more is required for full understanding than whatever is required for that. But although this formulation is particularly associated with Wittgenstein, what he intended by it is a matter of controversy.[3] The invocation of use evoked a cluster of ideas, and commentators have highlighted different elements in this cluster.

Wittgenstein begins the *Philosophical Investigations* (2nd edn, 1958) with a critique of a conception of language according to which

> Every word has a meaning. This meaning is correlated with the word. It is the object for which the word stands. (§l, p. 2)

If we are mesmerized by the idea of meaning as a 'correlation' between a word and another thing, we misconceive what it is to understand a language.

Wittgenstein has many things to say against this mesmeric conception. He is particularly concerned to draw attention to the diversity of language uses, the variety of speech acts linguistic utterances can be used to perform – the many things you can do with words. Language is not just used to assert and describe. Nor are words just used to designate things. But we shall not be concerned with various important points he makes about the diversity of language use. (Baker and Hacker, 1980, provide a comprehensive commentary.) Our topic can be pinned down by distinguishing two criticisms of the correlational model. The first, widely made by many philosophers interested in language at least from Bentham onwards, is that certain expressions which seem to designate something may turn out, on analysis of their use in sentences in which they occur, not to do so. This is shown by producing a paraphrase of sentences in which the expressions occur, which preserves the meaning of the sentences but eliminates the expressions. This point does not put in question the correlational model of meaning as such.

The other point is more thoroughgoing and deeper. It is that the model of designator and thing designated is a philosophically misleading prototype of meaning. In making this point, one does not need to deny that a designation or 'semantic value' is associated with every ineliminable non-empty term, in virtue of its meaning. For example, the word 'yellow' will designate the property *yellow* – or a Fregean concept or the class of yellow things, or whatever the right account of its semantic value is – and we will understand that (inexplicitly) when we understand 'yellow.' But we can ask what it is to have that understanding. The *sentence,* 'The English word "yellow" designates the property *yellow*,' cannot be employed to explain the meaning of 'yellow' to someone who does not understand the word. Its meaning can be explained to someone who already understands another language, by using *that* language ('"Yellow" en anglais signifie *jaune*.'). But to someone who does not already understand another language it must be explained in other ways. Attending to the ways in which the meaning of words is actually explained

gives us an overview of their use and thus of the rules which govern that use. These rules constitute their meaning in the language.[4]

This line of argument for the conception of meaning as use will be a main topic in what follows. I will call it 'the Constitutive Argument,' since it is about what constitutes such metalinguistic knowledge as that 'yellow' in English designates yellow. We return to it in §1.5 and again in §§3.1–3.2. But finally in this section I want to note a point which is often connected with the Constitutive Argument in Wittgenstein's discussions of language – and also with his reflections on rule-following. In *Philosophical Remarks* (1975), for example, Wittgenstein says,

> in a certain sense, the use of language is something that cannot be taught, i.e., I cannot use language to teach it in the way in which language could be used to teach someone to play the piano. – And that of course is just another way of saying: I cannot use language to get outside language. (p. 54)

Now if the use of language is what cannot be taught, and meaning is use, one might conclude that meaning cannot be taught. But Wittgenstein only says that in a certain sense it cannot be taught. What does he mean? Any rule or instruction given for the use of a word must be given in language, understood broadly to cover all signs. Signs can only convey meaning if at some point there is a natural uptake of how they are being used. It is that natural uptake which cannot be taught – it is a condition of the possibility of teaching a language to someone that teacher and pupil share it. In this sense "Language must speak for itself" (Wittgenstein, 1974, p. 40). In grasping a language-rule, I grasp its applications – but this cannot require grasping further rules determining what its application to particular cases is. A being which grasps and applies rules must have spontaneous normative responses about the *right* way to apply a rule in a given case: responses not determined by a further rule. That normative dimension of understanding a sign cannot be conveyed by instruction in rules, but is presupposed by the very process of instruction.

We shall come back to this point as well in §§3.1–3.2. For the moment I simply note its compatibility with the previous one, which was that rules which constitute the meaning of a sign should be thought of as rules for its use. Nothing we have said so far precludes the possibility that such rules of use may be stated explicitly and systematically for a whole language, yielding thereby a theory of meaning for that language. Wittgenstein would probably have opposed such a view. But although it is true that rules of use presuppose normative responses which are not themselves codifiable as rules, that in no way shows that the rules do not exist or cannot be systematically exhibited.

So we turn now to the idea that meaning-rules are rules of *use*, rules for doing things with words.

1.3 The Priority Thesis and the Epistemic Conception of Meaning

Consider the speech act of assertion. It may or may not be the case that an account of it has to be given before we can give an account of other uses of language. It is at least clear that the assertoric use is a main use of language, for which there must be rules of use.

The most straightforward assumption to make about those rules would be that they combine to specify when a sentence in a language is correctly assertible. So where L is a language and S is a sentence in L, the specification has the form

(RA) S is correctly used to make an assertion in L if and only if …

Let us call the condition indicated by the dots on the right-hand side of 'if and only if' the *assertion condition*. Rules for the use of a word would contribute to determine assertion conditions for sentences containing that word.

In (RA) the notion of correctness is being used in a particular sense. It is correct, in the relevant sense, to use the sentence to make an assertion just if one is *justified* in making the assertion thereby conveyed – but questions of such matters as etiquette are not at issue. What is meant is that one is justified in thinking that assertion *true*. And the word 'true' is to be taken in its broadest sense, the sense in which any assertion whatsoever formally aims at truth. Truth in this sense may be partially characterized as a property F, such that for any assertion A whatsoever, if it is shown that there is no adequate ground to hold that A has F, reason (as against etiquette, discretion, etc.) requires withdrawal of A.

Why does the relevant notion of correctness relate in this way to the broad notion of truth? Because of what may be called the basic principle of the practice of assertion:

(A) One correctly uses a sentence to make an assertion if and only if one is justified in believing, of the proposition expressed by that use of the sentence, that it is true.[5]

Let us call this kind of correctness 'epistemic justification' – one uses a sentence correctly if one is epistemically justified in using it to make an assertion. So now we conclude that, in general, the assertion condition of a sentence will have to spell out its basic form of epistemic justification.[6]

In §2.3 we ask whether, even granted a conception of meaning as use, a sentence's meaning should be thought of as given *exhaustively* by its assertion conditions, or whether account should also be taken of the inferences it licenses. But perhaps our initial assumption – that rules fixing the assertoric use of a language should issue in direct specifications of the (RA) form – has been too speedy anyway? Look again at principle (A). It says that what one asserts and what one believes to be true is a proposition, not a sentence. If we reflect on that it may well strike us that the (RA) form over-ambitiously combines two tasks which should be kept separate. One task, that of the theory of meaning proper, is to specify for any sentence in L what proposition it expresses. (In the course of doing that in a finite systematic way, the theory will also have to specify for any expression in L what concept it expresses.) Another task is to give an account, for various kinds of propositions, of when one is justified in believing them to be true. This second task does not belong to the theory of meaning, but to epistemology.

Philosophers in the 1930s (Wittgenstein and the Vienna Circle) who took it that the way to specify the meaning of a sentence was (RA) also rejected this division between semantics and epistemology.[7] How are these theses connected?

A grounding idea is that *there is no language-independent account to be given of concepts and propositions*. To talk of concepts or propositions is simply to talk indirectly of the use of expressions and sentences in languages – classes of same-use expressions and sentences. Grasping a concept is understanding (the use of) an expression in a language. Grasping a proposition is understanding (the use of) a sentence in a language. Attitudes to propositions and concepts are attitudes to sentences and expressions in a language. We cannot *explain* understanding an expression or sentence as knowing what concept or proposition it expresses – as though that concept or proposition were an entity independent of language, and 'understanding what concept or proposition is expressed' were a matter of knowing the

correlation between the bits of language which do the expressing and the pre-existing non-linguistic item which is expressed.

Call this thesis the *priority thesis*.[8] It says that an account of concepts and concept-possession is dependent on an account of language-rules and language-understanding. It does not deny that it can be useful to talk of concepts and propositions. It is not denying the *truth* of principle (A). It is a positive thesis about what such talk amounts to. Talking about concepts and propositions is a way of talking about language-understanding, without specifying the particular language. It has a negative side – concepts and propositions have no explanatory role in the epistemology of understanding. We do not *explain* how a person understands the meaning of a word by saying that he or she possesses the concepts it expresses and knows that it expresses that concept. For possessing the concept just is knowing how to use the word (or some synonym) and that is what constitutes understanding it.

It is the priority thesis which seems to produce the conclusion that semantics and epistemology are one and the same. We may call this the *identity thesis*, for it denies that there are language-independent concepts which generate their own language-independent epistemic norms. There are only rules of language. Epistemic norms, the subject-matter of epistemology, are simply rules of classes of language – the subject-matter of semantics.

As I have noted, the slogan 'meaning is use' can be associated with a cluster of ideas in Wittgenstein's work, and its interpretation is controversial. It is clear that he himself directs it against the correlational model, and that he presents instead a conception of understanding as grasping language-rules which are like rules for making moves in a game. So he is not envisaging a reductive account of language-understanding in non-intensional terms, as some have thought (see, e.g., Horwich, 1995). To say that understanding consists in mastery of rules which are like rules of a game is still to give an intensional account – an account which attributes to language-users judgments about whether, for example, it is permissible or correct to utter a sentence. But we also thought it unlikely that Wittgenstein himself intended his emphasis on use to yield a systematic theory of meaning for a language. In order to leave that interpretative question clearly open, it will help to have a name other than 'use theory' for the view which does aspire to develop the idea of meaning as use systematically. Various names have been used – 'criterial semantics' (Baker, 1974; Peacocke, 1981), or 'anti-realist semantics' (Wright, 1987, ch. 7); 'verificationist semantics' (Putnam, 1983), or 'justificationist theory of meaning' (Dummett, 1993b). A first statement of this view is that ground-rules of meaning (for assertoric sentences) take the (RA) form, and that accounts of the meanings of words in a language must be given in such a way as to entail statements of that form for each assertoric sentence in L. Let us call it, non-committally, the *epistemic conception of meaning* (EM): 'conception,' in that it proposes what the *form* of a theory of meaning should be; 'epistemic,' because the meaning-rules it envisages state when assertion of a sentence is epistemically justified. This is only a first statement of EM: in §2.3, as I said, we shall consider the possibility of broadening it beyond this initial, verificationist form, letting it take into account what inferences assertion of a sentence justifies. But this form will do for the moment.[9]

The priority thesis seems to lead to the identity thesis and thus to EM. In identifying rules of language use with rules of epistemic justification it gives EM a particularly sharp and central role in philosophy. Just one story now gives a unified account of the meaning and the epistemology of L. The epistemic conception of meaning might just as well be called the semantic conception of epistemology. In effect it does away with the traditional philosophical discipline of epistemology. That does not make 'epistemic' a misleading word – it abolishes epistemology *because* it is an epistemic conception of meaning.[10]

This kind of view is central to logical empiricism. Logical empiricism held that there are only factual propositions – the province of science – and recommendations about how to speak or, more generally, what to do. There are no non-factual propositions, and there are no factual propositions which lie beyond the province of science. A language is a set of recommendations, or rules. The rules stipulate when a sentence in the language is assertible.

Think of the assertion condition as specifying an information state of the language-user. An important point is that every aspect of this state is accessible to the language-user. Whether or not one is in a state of experience, has a belief, has a justification for that belief – all this must be reflexively transparent if the rule is to be a rule of *use*. It must be possible in principle for me to tell, by reflection on my state of information alone, what it is and whether it warrants assertion of a sentence. If rules of use did not have this form I could not directly apply them: I would have to have a further criterion to tell whether the antecedent of the rule obtains.

Distinguish this from another point: must there be an effective procedure for deciding whether evidence warranting assertion of a sentence can be obtained or not? That is, must it always be possible to enlarge one's information state, by a specifiable method, to a point where one can authoritatively assert either that evidence warranting its assertion is available or that it is not? No. The requirement is that it should be transparent whether a sentence is assertible in an information state. *That* question must be effectively decidable. But the sentence itself need not in any sense be effectively decidable. One must be able to tell whether one's information state warrants the assertion 'There is evidence warranting assertion of S.'[11] If it does not, it's not required that one has a procedure for getting into an information state which decides the issue.

1.4 The Truth-Conditional Conception of Meaning

So the suggestion is that the priority thesis leads to EM, via the identity thesis. But we must now consider an analysis of meaning which seems to show that the suggestion is wrong. If this analysis is satisfactory, then the priority thesis does not entail the identity thesis, and therefore does not force EM.

The proposer of this analysis agrees that there must be rules which determine the correct assertoric use of sentences in L. But he insists on the point made in the previous section (§1.3) – those rules need only determine, for any particular sentence which can be used to make an assertion, *what* that assertion is. His claim is that we can formulate rules which do that, without making explanatory appeal to grasp of concepts and propositions, and without casting them in the (RA) form. They will be cast in such a way as to yield, instead, a statement for each assertoric sentence of the condition under which it expresses a truth (in the broad sense of truth invoked in §1.3). Such an account, he argues, tells us what each assertoric sentence says – and remains consistent with the priority thesis.

So instead of specifications of meaning of the (RA) form, this theory of meaning proposes to make do with specifications of the form

(RT) S is true in L if and only if *p*

('is true in L' means 'expresses a truth when used literally and assertorically in L').

Let us call this a *truth-conditional* theory of meaning. Like any other theory, it will need to make use of the compositionality of meaning: the fact that the meaning of a sentence is a function of the meaning of its constituent expressions. And it is this feature of the theory – its

appeal to compositionality – which is supposed to yield an account of understanding compatible with the priority thesis.

Consider for example the sentence, 'Ammonia smells.' Its meaning depends on the meaning of 'ammonia' and 'smells' and its syntactic structure. How might we spell out this dependence? Suppose the meaning of the words is given by 'dictionary' rules like this:

(1) 'Ammonia' is true (in English) of ammonia
(2) 'smells' is true (in English) of *x* if and only if *x* smells

And the syntactic structure is given by this 'compositional' rule:

(3) 'Fa' is true (in English) if and only if 'F' is true of that which 'a' is true of

Substituting 'ammonia' and 'smells' into (3) and using (1) and (2) we can deduce that

'Ammonia smells' is true (in English) if and only if ammonia smells.

So we know this equivalence solely on the basis of knowledge of those semantic rules of English in virtue of which (1)–(3) hold, plus the very basic logic involved in deriving it. That being so, the suggestion now goes, we know that the English sentence 'Ammonia smells' expresses the proposition that ammonia smells. For suppose that English sentence 'Ammonia smells' expresses a proposition P. Then I ought to be able tell that 'Ammonia smells' is true if and only if P is, just by knowing the semantic rules of English plus the basic metalogic of the theory. But let P = (say) the proposition that water is odorless. Then although it is true that ammonia smells if and only if water is odorless, I need to *know* that in order to recognize that

'Ammonia smells' is true in English if and only if water is odorless.

Although, in this example, the biconditional which I need to know is *a posteriori*, the point does not turn on that. Consider, for example, the proposition that $2 + 2 = 4$ if and only if $3 + 3 = 6$. This may be known *a priori*. But I still need to *know* it, as well as dictionary and compositional rules, to know that

'$2 + 2 = 4$' is true in English if and only if $3 + 3 = 6$.

In general, a sentence S in L expresses the proposition that *p* just if, by virtue of semantic conventions of L alone, S is true if and only if *p.* If I know an instance of this biconditional for every sentence in L which has an assertoric use, and I know it compositionally – through a grasp of the semantic value of the terms from which it is formed – then I have a complete grasp of L's assertoric power. So there seems to be no need to appeal to an account of the *assertion* conditions of sentences in L to account for the assertoric uses to which L may be put. The truth-conditional theory itself, so far as we have sketched it, seems consistent with the priority thesis. It does not mention concepts or propositions in explaining what it is to understand a language.[12] Moreover, it seems to provide a language-relative account of how one comes to know a proposition. Knowing the semantic conventions of L is knowing, for any sentence in L, what proposition it expresses. Which one? The one that is true solely on condition that that sentence expresses a truth. So grasping the proposition that ammonia

smells can consist in understanding English and then grasping it as the proposition which is true solely on condition that 'Ammonia smells' expresses a truth in English. (Or it can consist in understanding some other language L and grasping it as the proposition which is true solely on condition that the sentence in L which is in fact synonymous with 'Ammonia smells' expresses a truth.)

Thus the truth-conditional theory seems to be consistent with the priority thesis, in that it does not make explanatory appeal to the notion of language-independent concepts and propositions. On the other hand, it does not seem to require endorsement of the identity thesis either. It dovetails with the basic law of assertion, (A): I know that it is correct to assert a sentence S in L if and only if I have reason to think it expresses a truth – and the truth-conditional theory tells me what the truth-condition of S in L is. To know the *assertion* conditions of S in L I must both know its truth-condition, and also know the epistemology which links with that truth-condition. But that latter knowledge, knowledge of the appropriate epistemology, is not given by the truth-conditional theory of meaning itself. So the argument from the priority thesis to EM seems to break down.[13]

1.5 'Full-Bloodedness'

If it does break down, that must mean that the identity thesis is stronger than the priority thesis. It must mean that the priority thesis can be upheld consistently with a firm distinction between epistemic norms and rules of language. But can it be?

It is certainly true, as argued in the previous section, that if we know that

'Ammonia smells' is true (in English) if and only if ammonia smells

and we know that on the basis of knowledge of semantic conventions of English and very basic logic alone, then we know what proposition the sentence expresses – that is, that ammonia smells. But, as Michael Dummett (1974) has stressed, we can still ask what it *is* to know that 'Ammonia smells' is true (in English) if and only if ammonia smells. Call the proposition which is known – it is a metalinguistic proposition about English – 'M.' There is a difference between knowing M, and knowing that the metalinguistic *sentence* which expresses it is true. I could know that this sentence in the metalanguage (which in this case is itself English) expresses a truth without knowing what the object-language sentence meant, because I could know it to be true in English without grasping the proposition it expresses. (Compare: knowing that 'Lublin jest polskim miastem' expresses a truth in Polish, because you have been told authoritatively that it does, but not knowing what proposition it expresses.)

Can this point be deployed against the truth-conditional theory and in favor of EM? Is it an application of the Constitutive Argument (§1.2)? To deploy it in favor of EM one must take as one of its premises the priority thesis – which the truth-conditional theorist considered in §1.4 claimed to accept. The priority thesis says that to explain what it is to grasp a particular proposition is to give an account of what it is to understand some particular sentence or other. Now suppose we try to combine that with the claim that understanding 'Ammonia smells' is to be *explained* as consisting in a grasp of M. By the priority thesis, grasping M must then in turn be explained as consisting in understanding some sentence. What sentence? Well, we could say that grasp of M is explained by giving an account of what it is to understand 'Ammonia smells' itself – but that would now put us in an explanatory

circle. Apparently, then, we have to say that grasp of M is explained by giving an account of what it is to understand a sentence which expresses M. And then, by the same argument, we shall have to say that understanding that metalinguistic sentence will in turn be explained as grasping the higher-level metalinguistic proposition which specifies its truth-condition. Obviously, this won't do. It cannot be the case that every language is understood only by prior understanding of a metalanguage in which biconditionals about truth-conditions of sentences in the language are expressed.

But the choice between a vicious circle and a vicious regress arises from the attempt to combine the priority thesis with the claim that understanding a sentence is to be *explained* as consisting in a grasp of the metalinguistic proposition which specifies its truth-condition. Thus, if we accept the priority thesis we must reject that claim.

This spelling-out of the Constitutive Argument makes the priority thesis one of its premises. Similar reasoning forces rejection of the claim that understanding a word is to be *explained* as consisting in a grasp of a metalinguistic proposition – one which specifies its semantic value, or specifies the concept it expresses. Thus we are led to the conclusion that the theory of meaning must, in Dummett's words, be 'full-blooded' and not merely 'modest.' A modest theory of meaning, he says, is

> not intended to convey the concepts expressible in the object-language, but to convey an understanding of that language to one who already had those concepts.

while a full-blooded theory should,

> in the course of specifying what is required for a speaker to grasp the meaning of a given word, … explain what it is for him to possess the concept it expresses. (1993a, p. viii)

The point is that if we accept the priority thesis then we must reject the idea that understanding a word or a sentence can quite generally be explained as grasping a metalinguistic proposition which exhibits its meaning by specifying its semantic value or its truth-condition. On the contrary, we shall have to be able to say that grasping a metalinguistic proposition of that kind can consist in understanding the word or sentence which it is about. For example, grasping M can consist – if one's home language is English – in understanding 'Ammonia smells': the very same understanding as is involved, in that case, in grasping the proposition *ammonia smells*.[14] Explaining what it is to possess a concept or grasp a proposition becomes a task for the theory of meaning, and not for some other branch of philosophy. Hence there must be a part of the theory of meaning which does more than simply stating what expressions of the language are true of and deriving from that truth-conditions for sentences of the language. There *may* be a truth-conditional part of this kind, but there must also be a part which goes beyond it. And this part will conform to the epistemic conception of meaning.

But if we take this part to consist in the specification of assertion conditions for sentences in the language, won't the argument we have just considered apply to it as well? Won't it equally show that understanding 'Ammonia smells' cannot consist in knowing the proposition that 'Ammonia smells' is assertible iff … ?

To this the EM theorist's response is that knowing the assertion conditions of a sentence can consist in a *practical* ability to tell when it is right to utter it assertorically: to recognize information states as warranting or not warranting that kind of utterance of the sentence.[15] Precisely the same ability could, of course, be invoked to explain what it is to know the truth-conditions of a

sentence. But that is the EM theorist's point. To respond in this way would concede that grasping truth-conditions is not something over and above, independent of, mastery of assertion conditions. EM anchors understanding to a practical normative response.

Now all of this has proceeded on the assumption that the priority thesis is correct. But why cannot we reject that thesis, and accept an account of concepts and propositions which is not language-relative?

The most significant approach of this kind is *Platonism*. I use the term to refer to the view that concepts and propositions are non-spatio-temporal entities known by non-perceptual intuition. Platonism, combined with a truth-conditional view of meaning, may seem to offer an explanation of understanding. To know that 'straight' is true in English of straight things is to grasp, by non-perceptual intuition, the concept of straightness and to know that it is expressed by the English word 'straight.'

One can object, in this purported explanation of understanding, to the appeal to non-empirical intuition of concepts and propositions. But there is a different and clinching consideration – I will call it the 'no-intrinsic-meaning argument.' Wittgenstein uses it in various places, such as the following:

> In attacking the formalist conception of arithmetic, Frege says more or less this: these petty explanations of the signs are idle once we *understand* the signs. Understanding would be something like seeing the picture from which all the rules followed, or a picture that makes them all clear. But Frege does not seem to see that such a picture would itself be another sign, or a calculus to explain the written one to us. (1974, p. 40)

Wittgenstein's point is that there is no such thing as an object which has intrinsic meaning, that is, which (a) has meaning irrespective of having that meaning conferred on it and (b) is such that knowing it and knowing its meaning are one and the same. Even if we had access to objects in a Platonic third world, and had a mapping of terms and sentences onto these objects, that would do nothing for us unless those objects were already signs – signs which had intrinsic meaning. (If their meaning were not intrinsic, the questions of what it is for them to have meaning and what it is for us to understand that meaning would again arise.) The same would go for a picture in the world of physical or mental representations. The objection does not have to do with the particular world we are talking about. It is not a positivistic or even a naturalistic objection. (Blackburn, 1984, ch. 2 sets out a version of it and applies it to Fodor's 'language of thought' hypothesis.)

It is certainly a devastating argument against the view that a person's understanding of language is to be explained in terms of his or her possession of concepts and propositions – *if possession of concepts and propositions is taken to be quasi-perceptual access to a class of objects*. So taken, concept-possession could not *in principle* have a justificatory or explanatory role. But we have not shown that the only alternative to a language-relative account of concept-possession is one which treats concepts as intrinsically meaningful objects, mysteriously accessible to us. That would have to be shown, if we sought to derive the priority thesis from the no-intrinsic-meaning argument alone. Sometimes Wittgenstein seems to appeal to a dichotomy between an account of understanding which invokes access to intrinsically meaningful objects and one which invokes only grasp of language-rules:

> the mere fact that we have the expression 'the meaning' of a word is bound to lead us wrong: we are led to think that the rules are responsible to something not a rule, whereas they are responsible only to rules. (Reported in Moore, 1959, p. 258)

The apparent suggestion here is that if we avoid reifying 'the meaning' of a word into an intrinsically meaningful object then we have to accept that the rules governing its use constitute its meaning and are not 'responsible' to anything else. But may there not be a middle way – an account of concepts which neither reifies them nor makes them language-relative – and, given such an account, will it not be the case that a word which expresses a concept will have its meaning in the language set by rules which are 'responsible' to, or dovetail with, language-independent features of that concept? An account fitting this description would be this: to grasp a concept is to respond to a pattern of epistemic norms. It is to be disposed to accept a particular pattern of thought-transitions as primitively justified. Epistemic norms, however, are not themselves rules of language. A theory of meaning for a language is not in the business of describing them; that is a matter for the theory of concepts (or epistemology). Thus the theory of meaning can describe the rules of the language truth-conditionally, and will dovetail with an account of concepts which is neither language-relative nor Platonistic but characterizes possessing concepts as acknowledging patterns of epistemic norms.

Such an approach certainly has to reject the priority thesis, but it still accepts the no-intrinsic-meaning argument against Platonism. It provides, one might say, a full-blooded theory of concepts and a modest theory of meaning. So the question arises whether there is a case for the priority thesis which is independent of the no-intrinsic-meaning argument. We will return to these matters in §§3.1–3.2. But first we must examine further the conception which, as it now seems, is indeed forced if the priority thesis is accepted: that is, the epistemic conception of meaning.

2 Verificationism

2.1 Verificationism: Meaning and Truth

In the 1930s, verificationist conceptions of meaning were advanced by Wittgenstein and by philosophers of the Vienna Circle. But the connection between verificationism and EM is not straightforward. There can be non-epistemic versions of a verificationist view of meaning. And there can be non-verificationist forms of the epistemic conception of meaning. In considering these points we shall have to develop an account of EM which goes beyond the initial statement of it in §1.3.

I will use the term 'verificationism' to refer to a view of *meaning*, not, at least directly, to a view of truth. Verificationism is the view that understanding a sentence consists in grasping what information states would verify it. An information state verifies a sentence just if a person in that state is warranted in asserting it. All significant sentences have assertion conditions – their meaning can be displayed in the (RA) form.

In contrast, a verificationist view of *truth* holds that truth is verifiability. A sentence is true if and only if it is verifiable, that is, if and only if there is evidence warranting its assertion. To say that there is such evidence is to say, roughly, that a state of information warranting assertion of the sentence can be reached by us through an investigation which improves our current state of information – as it bears on the question of the sentence's truth or falsity – as much as it is actually possible to improve it.[16]

The difficulties with such a view of truth are notorious. Consider, for example, the two sentences 'Charlemagne's favorite color was magenta,' and 'Human beings cannot grow above 12 feet tall.' As far as the verificationist conception of *meaning* is concerned, both

sentences have a meaning. We know what kinds of evidence would warrant their assertion – for example, a text from the time of Charlemagne, which in general had the marks of reliability, and which recorded that Charlemagne often commented that his favorite color was magenta; inductive evidence that human beings never reach 12 feet together with theoretical considerations (e.g., relations between the height of an animal, its volume, mass, and muscular power, considerations of evolutionary fitness) which indicate that they could not. But we also know that evidence of that kind may not actually be available. It may not be possible to improve our information to the point where we are warranted either in asserting or in denying these sentences. Do we want to say that in that case those sentences are neither true nor false? Does a sentence's possession of truth-value depend on such contingencies?

To be sure, there are various ways of spelling out the word 'possible' in the phrase 'improving our information as much as it is possible to do.' Verificationists about truth characteristically idealize the notion of verifiability. For example, they may idealize the computing abilities of the agent which does the verifying, or its ability to move in space and time. But such idealized notions of verifiability cannot be identical with the concept of assertibility which is required for a verificationist view of meaning of the *epistemic* type. (This qualification will be explained in a moment.) For there the concept required, as was said in §1.3, is that of an assertion condition. And whether or not the assertion condition of a sentence obtains – whether or not the sentence is assertible in the language-user's information state – is something that must be transparent to the language-user. This transparent notion of assertibility cannot be identical with any non-transparent notion of verifiability – one which requires hypotheses about what would be assertible by an ideal agent.

There is, in fact, no straightforward route from a verificationist conception of meaning of this epistemic kind to a verificationist account of truth. It requires an unobvious philosophical argument to make the connection. (For arguments intended to make the connection see Dummett, 1959a; 1978b; Wright, 1987, "Introduction"; for criticism, see Skorupski, 1988.) On the other hand, there is a route from verificationism about truth to a non-epistemic type of verificationism about meaning.

A historical excursus will provide helpful background here. In conversations which he had in the late 1920s with Schlick and others from the Vienna Circle, Wittgenstein took a very strict verificationist line about meaning. The record made by Friedrich Waismann of these conversations contains many formulations of it – for example, 'The sense of a proposition is the method of its verification' (Wittgenstein, 1979, p. 79; cp. e.g., p. 227). Wittgenstein takes the notion of verifying a sentence quite strictly to mean '*indefeasibly* establishing its truth.' He describes (in Waismann's record) two conceptions of verification. According to one, the one he rejects, I cannot verify a proposition, for example 'Up there on the cupboard there is a book,' completely.

> A proposition always keeps a back-door open, as it were. Whatever we do, we are never sure that we were not mistaken.
>
> The other conception, the one I want to hold, says, 'No, if I can never verify the sense of a proposition completely, then I cannot have meant anything by the proposition either. Then the proposition signifies nothing whatsoever.'
>
> In order to determine the sense of a proposition, I should have to know a very specific procedure for when to count the proposition as verified. (Wittgenstein, 1979, p. 47)

Applying the procedure must yield a definite and indefeasible result. A consequence of this view is that general 'propositions,' which are not verifiable in the strict sense, have to be treated as 'hypotheses' rather than as genuine propositions.

But why must we adopt this very strict notion of verification? Why cannot verification just consist in achieving a state of information which warrants assertion? And why cannot that verifying state be defeasible? We know what kind of evidence would justify assertion of 'Charlemagne's favorite color was magenta,' or 'Human beings cannot grow above 12 feet tall.' We also know that that sort of evidence could be defeated by further evidence. We know that these sentences always 'keep a back door open,' that there can be no such thing as verifying them 'completely.' In short, why can't we work with 'defeasibly justify assertion of,' not 'conclusively establish the truth of'?

Whatever the reason for Wittgenstein's extremism in these Viennese discussions, his remarks usefully highlight the difference between two quite distinct philosophical perspectives from which verificationism can grow.

In one of these, it emerges from a combination of two things. The first is a conception of meaning which holds that a sentence has meaning by picturing a state of affairs (so, a species of the truth-conditional view). The second is an ontology which conceives of reality as a totality of states of affairs, thought of as immediately encounterable in experience. To understand a sentence is, then, to be able to picture – and for this kind of verificationism this means to be able to imagine experiencing or observing – the state of affairs which makes it true. And to verify a sentence or its negation is, so to speak, to run through the totality to the appropriate point and check by direct observation whether or not the state of affairs pictured by the sentence obtains. Verification, conceived in this way, is conclusive.

Here the central idea is that understanding a sentence is being able to represent to oneself what it would be like to encounter in experience the state of affairs which makes it true. Its affinity with Wittgenstein's *Tractatus* philosophy is suggestive. Though the Tractarian knowing subject is a highly elusive item, it is not implausible to think of it as being able to sweep at will through the states of affairs, or configurations of Tractarian objects, to which elementary sentences correspond, directly checking whether or not any elementary sentence is true.

But this last idea, with its phenomenalistic implication, could be loosened. The loosened version says that if one can describe, at least 'in principle,' what it would be like to have this encounter, the sentence is verifiable. It may not be possible to arrange to have the encounter, but the state of affairs is at least ideally verifiable – one can imagine a knower ideally transported to the site of the state of affairs and having the encounter. And now we have a verificationist notion of *truth* which can combine with a truth-conditional view of meaning to yield a kind of verificationism about meaning. Call this the positivistic route to verificationism. It rests on a positivist ontology of the real as the in-principle observable, and the verificationism which results is not a species of the epistemic conception of meaning.

But Wittgenstein does not say in these conversations that the meaning of a sentence is the picturable state of affairs which would verify it, render it true. His emphasis is on *methods* of verification. When he says on p. 227 (Wittgenstein, 1979) "The sense of a proposition is the method of its verification," he is quoted as continuing:

> A method of verification is not the means of establishing the truth of a proposition; it is the very sense of a proposition … To specify it is to specify the sense of a proposition. You cannot look for a method of verification. A proposition can only say what is established by the method of its verification.[17]

The next paragraph plays on the idea of thought as a movement with a determinate direction, set off in search of an answer to a question. The sense of both the question and the answer is given by the direction of the search (direction-sense).[18] Connectedly, Wittgenstein insists that different methods of verification ('thought-movements' with different directions) produce different senses. Such a view is not suggested by the positivistic route to verificationism. For as far as that conception goes I might be able to travel in various ways to the point of verification, the point at which I check by direct inspection whether or not the relevant state of affairs obtains. Equally, Wittgenstein's remark that you cannot look for a method of verifying a proposition – that is, first understand it and then look around for ways of verifying it – does not sit well with that positivistic conception.

Overall, then, it seems that what Wittgenstein presents in these conversations is a strictly operational kind of verificationism, a species of EM.[19] But without an underlying positivist (and indeed phenomenalist) impetus, there is no case for such strict operationism. The arguments for EM as such do not enforce it. Later Wittgenstein greatly broadened his operationist version of EM, taking into account the consequences for practice of an assertion as well as the operations which license it. To understand an assertion it is not enough to be told when you're licensed to make it: you need to know what it's a license to *do*, what consequences flow from it, ultimately for action.

The result is a fully liberalized, and pragmatized, conception of meaning as use. Understanding a word or sentence is knowing what can be done with it in communication and action, knowing the rules which govern its role in our practices of assertion and inference. The use of a sentence is as much a matter of the practical conclusions you can draw from an assertion of it as of the conditions under which you can assert it. The epistemic conception of meaning has now been framed in its full breadth. It is not derived *from* the idea that truth is verifiability. (The contemporary version of this line of thought, from verificationism about truth to verificationism about meaning, is to read 'is true' in a truth-conditional theory of meaning as equivalent to 'is assertible.' It is presented and discussed in Wright, 1987, chs 1, 2, and 9; see also Strawson, 1977.) Nor does it provide any obvious route *to* a link between verifiability and truth. In both cases the alternative, present in this tradition since the Viennese 1930s, is to endorse some deflationary view of truth. EM can realistically recognize that some – or, indeed, all – of the ways in which we acquire warrants for asserting a sentence are defeasible. An inquiry which was good enough to justify the assertion may be superseded by further inquiry which defeats that assertion, that is, leads to an improved information state in which the assertion is no longer justified. The epistemic conception, comprehensively stated, is compatible with such defeasibility in a way that the strict verificationism enunciated in the passage from Wittgenstein quoted above is not.

In fact if we adopt this comprehensive epistemic conception of meaning (for short I will call it 'the comprehensive EM') we have to reject not only strict verificationism but verificationism as such. For to say that evidence defeasibly warrants an assertion that *p* is to accept as intelligible 'There is evidence warranting the assertion that *p* but it is not the case that *p*.' This sentence must have meaning since it appears as a constituent in 'It is logically possible that there is evidence warranting the assertion that *p* but it is not the case that *p*.' The latter sentence is one which we are justified in asserting if we are justified in holding that there can be evidence that *p* which is sufficient but defeasible. It is the way we express, in the language, the proposition that evidence is defeasible. Yet the constituent sentence itself is never verifiable. Thus, if a sentential constituent of a meaningful sentence must itself be

meaningful, we have a sentence in the language which is meaningful but not verifiable. So we cannot liberalize verificationism to allow for defeasible verifications: if we liberalize it we have to go beyond it.

We return to this point in §2.3. But first we will consider what account the comprehensive EM can give of the meaning of the logical operators. They are of great importance – witness the fact that sentences like the one above, whose intelligibility refutes verificationism, contain them.

2.2 The Meaning of the Logical Operators

We can give an account of the meaning of logical operators (the operators of sentential logic, and the quantifiers of predicate logic), as of any other expressions, contextually: by giving an account of the way they contribute to the meaning of sentences in which they occur. But on the verificationist view of meaning, an account of the meaning of complex sentences containing the logical operators will have to take the RA form. So our account of the meaning of logical operators, on the verificationist view, must spell out how they contribute to the assertion conditions of sentences in which they occur. And it is natural to think that the way in which they contribute is by mapping the assertion conditions of the constituent clauses of the complex sentence onto an assertion condition for the complex sentence itself; just as in a truth-conditional theory they map the truth-conditions of the constituent clauses onto a truth-condition for the complex sentence itself. Call this the 'assertion-condition-functional' (ACF) view of their meaning, as opposed to the truth-condition-functional (TCF) view of their meaning advanced by the truth-conditional approach. As Dummett famously put it:

> *We no longer explain the sense of a statement by stipulating its truth-value in terms of the truth-values of its constituents, but by stipulating when it may be asserted in terms of the conditions under which its constituents may be asserted.* (Dummett, 1959a, pp. 17–18 in 1978a. Emphasis in the original)

The ACF view leads to the conclusion that verificationism will require rejection of classical logic. For consider 'P or it is not the case that P,' and compare its truth-condition – it is true if either 'P' is true or 'It is not the case that P' is true – with the assertion condition it will have on Dummett's proposal: it is assertible if either 'P' is assertible or 'It is not the case that P' is assertible. This latter account of the meaning of 'or' will allow us to assert 'Either magenta was Charlemagne's favorite color or it was not' *only* if we have evidence warranting the assertion that it was or evidence warranting the assertion that it wasn't. Classical logic, on the other hand, allows us to assert the sentence outright. To save classical logic, one might try supplementing one's account of the meaning of 'or.' For example, we could say that a sentence of the form '*p* or *q*' would be assertible just where '*p*' is assertible, or '*q*' is assertible, *or where* '*q*' = '*not-p.*'

There are serious obstacles to this suggestion; but they need not concern us.[20] For, whatever one's view may be about the desirability or otherwise of maintaining classical logic, there is something wrong with the idea that an account of the logical operators must be ACF. The point turns on this: evidence that there is no evidence that *p* does not warrant asserting that it is not the case that *p*. For example, we may have sufficient warrant to assert that there is no evidence that Charlemagne's favorite color was magenta; but that does not

justify us in denying that Charlemagne's favorite color was magenta. Now consider a pair of sentences of the form '*p*' and 'It is assertible that *p*.' They have the same assertion conditions; any information state which warrants assertion of the one warrants assertion of the other. Consider next the pair 'It is not the case that *p*' and 'It is not assertible that *p*.' These clearly do not have the same assertion conditions, for the reasons just given. It follows that an ACF account of the meaning of 'not' cannot be acceptable.

On any view, it is not part of our practice to regard a demonstration that there is no evidence that *p* as tantamount to a warrant for asserting 'It is not the case that *p*.' The reason is obvious. The world is not totally surveyable by us. There are true propositions about it which we do not have the evidence to assert. Evidence can sometimes be sufficient, though defeasible; but it can also be simply insufficient.

So, also, 'If *p* then *q*' cannot mean, for example, 'If it is verifiable that *p* then it is verifiable that *q*.' For let '*q*' = 'there is no evidence that *p*.' The sentence, 'If *p* then there is no evidence that *p*' is perfectly intelligible and may indeed be assertible. ('If the Prime Minister is a master-criminal there is no evidence that he is. For a master criminal is totally effective in covering his traces.')[21] Both '*p*' and 'there is evidence that *p*' have assertion conditions, but the assertion conditions of the conditional cannot be a function of them.

But does the comprehensive EM have to give an ACF account of 'not' and 'if'? Well, there is no ban on its using the word 'true' in formulating assertion conditions for complex sentences. For it does not deny that a person who understands a sentence S in L can thereby be said to know that S is true in L if and only if *p* (where the sentence which replaces '*p*' has the same semantic content as S). On the contrary, it says that knowing that metalinguistic proposition just is understanding S (see §1.5) – and understanding S in turn, according to a comprehensive EM, consists in mastery of its use in the language – of when it is assertible and what can be inferred from it.

So a comprehensive EM does not require that accounts of the meaning of logical operators must be ACF. It can allow that users of L who understand, and thus grasp the truth-conditions of, elementary sentences in L (those not containing the operators) may also have a truth-functional understanding of the operators. This view, incidentally, does not require that the meaning of those elementary sentences is unaffected by the introduction of operators into L. If introducing an operator into L changes the inferential power of a sentence which does not contain that operator, it also changes its use in L and thus its meaning. But this does not offend the compositional principle, that the meaning of a sentence is determined by the meaning of its constituents. That principle does not preclude the possibility that introducing a new operator into L changes the meaning of sentences in L. It only says that the meaning of a sentence formed with the new operator is a function of the meaning of its constituent sentences.

Let me illustrate by reference to the word 'not.' A truth-functional specification of its meaning will say: 'It is not the case that *p*' is true if and only if '*p*' is not true. If I know that, I can infer that

'It is not the case that *p*' is assertible if and only if it is assertible that 'p' is not true.

So I know the assertion condition of 'It is not the case that *p*' – so long as I can recognize the conditions which warrant denial of '*p*' (i.e., assertion that '*p*' is not true). But I cannot, from the assertion condition of a given sentence, mechanically derive the assertion condition for its denial, and hence not the condition for assertion of its negation either. So this is an

account of the assertion condition of 'It is not the case that *p*' which is not ACF. Nothing in the comprehensive EM requires that a semantics for the word 'not' should equip me with the ability to recognize when denial of any arbitrary English sentence is justified, solely as a function of its assertion condition. A semantic theory for English tells me that the correct way to negate an English sentence '*p*' is by saying 'It is not the case that *p*.' It registers the semantic complexity of negations by delivering truth-conditions for negations as a function of truth-conditions of the sentences negated. In doing so it enshrines the substantive principle that negation of S is justified just if denial of S is: a fundamental normative feature of our inferential practice. But semantic theory has no mission to tell me any more than that. Of course, on the epistemic conception of meaning there must still in principle be an account of one's understanding of the assertion conditions for denial of various kinds of sentence. But these may be very multifarious and will not be functions of the assertion conditions for '"P" is true.' The same goes for the other truth-functional operators.[22]

2.3 Beyond Verificationism

We noted in §2.1 that verificationism cannot be liberalized without being rejected. Liberalization means recognizing that the best available evidence may (a) be insufficient and (b) when sufficient at present, may yet in future be defeated.

For example we are entirely justified in saying that Charlemagne's favorite color may have been magenta even if there is no evidence warranting the assertion that it was or was not. And we are also justified in saying that, while there are currently sufficiently good scientific grounds for thinking that nothing can travel faster than light, it remains possible that theoretical advances in future may defeat them.

More generally, we are justified in holding that (1) there are sentences which are true even though no one has sufficient evidence for asserting that they are, and (2) that there are sentences which we have sufficient evidence to assert, but which are not true. Both these general propositions, about our ignorance and fallibility, are justified as internal consequences of our overall commonsense and scientific conception of the physical world (of which classical logic is currently a part), our place in it, the way we get causal signals from it, and so on. The intelligibility and truth of (1) and (2) cannot be denied; but at the same time there can be no warrant for asserting any of their instances.

So those instances, for example '"Charlemagne's favorite color was magenta" is true but there is insufficient evidence to assert "Charlemagne's favorite color was magenta,"' or 'We are justified in asserting "Nothing can travel faster than light" but that sentence is not true,' have no free-standing assertoric role in the language. There are no circumstances which justify their assertion. Their only role is as constituents in complex assertions, embedded, for example, in the context "It is possible that …," "It could be true that …," or in conditionals or negations. But it is still a role; and it is a grasp of that role which, according to the comprehensive EM, constitutes our mastery of their meaning.

The truth in verificationism is that where a sentence can have free-standing assertoric use, grasp of its meaning requires mastery of that use. But some complex sentences formed by sentential operators have a meaning only in virtue of their role in inference and their embedding in more complex sentences still. Where a sentence has a free-standing assertoric use, a person who understands it will know that it has that use and thus will have a grasp of its assertion conditions. But where a sentence does not have such a use, but can still figure in embeddings and inferences, that is what is grasped by someone who understands it.

3 Rules and Norms

3.1 Concepts as Cognitive Roles

In §§2.1–2.3 we attempted to set out EM in its broadest, most plausible, form. But we must now go back to the questions raised at the end of §1.5. That section argued that the priority thesis amounts to the identity thesis and imposes an epistemic conception of meaning or, otherwise put, a semantic conception of epistemology. We saw how Wittgenstein's no-intrinsic-meaning argument destroys any conception of meanings or concepts as intrinsic signs. But we also saw that the no-intrinsic-meaning argument seems to fall short of establishing the priority thesis and thus EM.

Grasping the meaning of a word cannot consist in cognizing an intrinsically meaningful object. But this does not refute the simple point that to understand a word *is* to possess a concept and know that the word expresses the concept. It merely shows that possessing the concept is not a matter of cognizing any such object. The right response to Wittgenstein's no-intrinsic-meaning argument may be a better account of concept-possession than that of the Platonist (or the 'language-of-thought' theorist).

A better account is that to possess a concept is to acknowledge certain cognitive moves as justified. Grasping concepts is acknowledging norms. By analogy to the slogan that meaning is use, one may say that *concepts are cognitive roles*. The no-intrinsic-meaning argument does not decide the choice between the two slogans.

Are the slogans complementary, or does one make the other redundant? It is a question of the difference between norms and language-rules. By a 'norm' I mean a true normative proposition about reasons. An *epistemic* norm is about reasons to believe – about the relation '… gives *x* reason to believe that *p*.' So the slogan 'Concepts are cognitive roles' says that to possess a concept is to acknowledge a pattern of epistemic norms. In contrast, a rule is not a *proposition* at all. It cannot be said to be true or false. It is the content of an explicit stipulation or implicit convention. The priority thesis comes down to saying that we cannot treat purported epistemic norms as ultimately distinct from *rules* of a language. Talk of norms constituting a concept must reduce to talk of language-rules constituting the meanings of words.

The no-intrinsic-meaning argument does not establish this thesis. We must look elsewhere – to that extraordinarily influential assumption which (as we noted in §1.3, in discussing the priority and identity theses) was made by Viennese logical empiricism. It was also made by Oxford ordinary-language philosophy, and indeed Quinean naturalism. The assumption is that all propositions are factual. Assertoric and judgable content is factual content.[23] In that case, if there are normative propositions there must be a domain of 'normative facts.' Well, we do talk about 'the fact that' one ought to come to the assistance of distressed people, or 'the fact that' one ought to accept the simplest explanation of the data. But we are not, I think, indulging in ontology. There is a substantial, ontologically committing use of the word 'fact': in this use of the word the idea of 'normative fact' seems to be a kind of category mistake. The stubborn thought that makes it seem a category mistake is a cousin, one might say, of the no-intrinsic-meaning argument. It is the thought that no fact, in any world (natural or non-natural), is intrinsically normative. Acknowledging a norm cannot *consist* in recognizing a fact. Norms are no more facts than meanings are things. But it is in this ontologically committing sense of 'fact' that the claim that all propositions are factual is to be understood.

If all propositions are factual and there are no normative facts, normative utterances, such as 'You ought to come to the assistance of distressed people,' or 'You ought to accept the simplest explanation of the data,' cannot be assertions but must rather be understood as recommendations, proposals, prescriptions, and so forth. In particular, then, it can become plausible to hold that the alleged epistemic norms which constitute concepts should really be seen as prescriptions as to the use of words. But this conclusion is not enforced by the powerful double-barreled weapon that says no object is intrinsically meaningful and no fact intrinsically normative. It requires the further claim that all assertoric content is factual. Only then do we get the dichotomy of facts and rules which generates the priority thesis and EM.

Although Wittgenstein often seems to assume the dichotomy (as in the second passage quoted on p. 82) it is also Wittgenstein, especially in his later thinking, who effectively drives a wedge through it in his reflections on what it is to follow a rule. He highlights the point, noted in §1.2, that to apply a rule is to exercise normative judgment. What view he takes of it, having highlighted it, is a matter of dispute. Here I am assuming, contrary to some readings of his philosophy of language, that he does not intend to *deny* that the question, 'Has the rule been applied correctly?' can have a true answer. His view is not the nihilist one that there is no true answer, or the extreme-conventionalist one that the answer in every case expresses a decision. He accepts that it can be determinately true that if you're following the rules of English you ought to call this patch here 'yellow' (though there can also be vague or indeterminate cases). I also assume – contrary, admittedly, to much current discussion – that Wittgenstein was not a reductionist. It was not his view that 'If you're following the rules of English you ought to call this patch here "yellow"' has a non-normative truth-condition, consisting, say, in a fact about the speech-dispositions or mental states of certain language-users. But if nihilism, radical conventionalism, and reductionism are all false then we have here an example of a normative judgment which corresponds to no fact (in the ontologically committing sense).[24] The upshot is that a thinker who follows rules must grasp norms *as well as* facts and rules. Commitment to the existence of norms is thus entailed by our very description of an entity as a rule-follower – if there are rules, the dichotomy of facts and rules is not exhaustive.

Applying a rule involves a spontaneous normative capacity which is reducible neither to judgments about what is the case nor to familiarity with conventions or stipulations. But why should interpretative normative judgments, judgments about the right way to apply a rule to a case, be the *only* instances of true normative propositions? We naturally and stably converge on many primitive judgments about what there is reason to think, feel, or do. Spontaneity and stability of normative judgment is present in all these cases. They are genuine judgments; no more is needed to show they have genuine propositional content.

Now we can formulate a real contrast between an epistemic conception of meaning and an epistemic conception of content (or concepts). Both hold that a truth-conditional theory of meaning must be supplemented if one wants a full account of language-understanding. And both can be said to hold that the supplement must be an account of concepts as cognitive roles. But EM takes it that an account of the cognitive roles of concepts reduces to an account of rules for use of expressions in a language. It holds that the required supplement is still *semantic*. On this view, there is a level of semantic theory which describes conventions for introducing and eliminating terms in a language. Conventions stipulating when a sentence is assertible and what is inferable from it are determined by them. They constitute the language, and the level of semantic theory at which they are stated – call it 'the cognitive-role level' – is more fundamental than the truth-conditional level. In contrast, an epistemic

conception of content ('EC' for short) takes the objectivity of norms seriously, and holds that an account of concepts can consist in an account of the epistemic norms regulating their introduction and elimination in one's thinking. Such an account – a theory of epistemic norms – is not a level of semantic theory, for it does not purport to describe rules of a language. It denies the identity of semantics and epistemology. As far as the semantics of a language is concerned, it can hold that a truth-conditional account is fully adequate.[25]

Many questions are raised by this approach; a number of them are analogous to questions which arise for a comprehensive EM. Thus one can ask how a theory of epistemic norms, as well as a theory of linguistic rules of use, copes with the phenomenon of defeasibility; and one can ask how concept-constituting norms, or rules, determine an extension for a concept. These are crucial questions, but they will not be pursued here. The next and final section takes up a very important and attractive corollary of EM: the account it yields of how *a priori* knowledge derives from grasp of meaning.

3.2 Aprioricity and Normativity

An epistemic conception of meaning greatly enlarges the empiricist idea that aprioricity is analyticity – that an *a priori* warrant for an assertion is one obtainable from a grasp of its meaning alone. Because it introduces rules of language at the cognitive-role level it is able to give a new account of analyticity which differs from what one might call the Kant/Mill account.

In the latter, a class of sentences is identified as uncontroversially empty of content, or a class of inferences as uncontroversially 'merely apparent'; and then these, together with sentences or inferences reducible to them by explicit definitions, are defined as analytically true. Take, for example, 'Anyone who is a father is a parent' or, 'He's a father. Therefore he's a parent.' The explicit definition is '"*x* is a father" = Df "*x* is male and *x* is a parent."' The contentless sentence might be 'A father is a father,' and the inferences acknowledged as merely apparent would in this case include and-elimination. But as Mill particularly emphasized, this account of analyticity does not guarantee that *all* logic is analytic. It is not uncontroversial that all logically valid inferences are merely apparent, even if it is uncontroversial that and-elimination is. (If even this is rejected, the class of analytic truths is even smaller: e.g., 'Tomorrow is the day after today.') In this respect, the Kant/Mill account contrasts with the 'Kant/Frege' account, which characterizes analyticity outright as derivability, with explicit definitions, from logic. However, it does not (in Frege's case at least) claim that analyticity is truth by virtue of meaning alone, or that analytic propositions are empty of content; and it is therefore unacceptable to a clear-headed empiricist. In contrast to both of these approaches, then, the new account of the *a priori* generated by EM *does* simultaneously claim that all logic is analytic and that analyticity is truth by virtue of meaning alone. It promises an empiricist account of the aprioricity of logic and mathematics. This has been perhaps its most influential feature.[26]

In the new account, as in the Kant/Mill account, a sentence is *a priori* or analytic when a justification for asserting it can be derived exclusively from a grasp of its meaning. But the rules which constitute that meaning will now include introduction and elimination rules statable only at the cognitive-role level. An example will explain what I mean. Consider the following introduction rule for the English word 'yellow':

(1) The occurrence of a visual experience as of a yellow object in one's visual field warrants, in the absence of defeating information, assertion of the sentence in English 'There's something yellow there.'

This is a rule formulated at the cognitive-role level. In contrast, if (as is plausible) 'yellow' is semantically simple, then a truth-conditional semantics for English will contain only the following dictionary rule:

(2) '"yellow" is true (in English) of *x* if and only if *x* is yellow.'

Notice that as I have formulated (1) the relation *warrants assertion of* holds between a state of visual experience – something which is not a sentence – and a sentence. Many philosophers, both friends and foes of EM, would find this unacceptable. They assume or argue that the relation can only hold between sentences.[27] But the only relevant constraint on an object which satisfies '… warrants assertion of S,' where 'S' can be any sentence, seems to be that it must have content and be transparent (in the sense of §1.3). A visual experience or a memory has content and is transparent, and so it satisfies that constraint. Some rules at the cognitive-role level will link warrants for asserting sentences to warrants for asserting other sentences (specifically, in the case of logical connectives, metalinguistic sentences – see §2.2). But if a language has empirical content at all it must contain rules linking the assertibility of certain sentences in the language to the language-user's experience and memory. In the spirit of stating EM in the most liberal way possible, we should allow that a fully comprehensive EM account can include them.

Consider now the following normative proposition:

(3) The occurrence of a visual experience as of a yellow object in one's field of vision justifies, in the absence of defeating information, a judgment that there's something yellow there.

This is not a metalinguistic statement of a rule of English as (1) is, but a normative proposition stated in English. What is the relation between them? The EM theorist must maintain that (3) is in some way an expression of (1) alone. It cannot be a genuine normative proposition. Rather, sentence (3) is 'assertible *a priori*' in English because its warrant derives solely from a rule of the language – for English the rule will be (1), while for other languages which have a sentence synonymous to (3) it will be a rule analogous to (1). Let us allow, for the sake of argument, that the details of this can be filled in coherently. However it is done, the crucial point is that it provides an explanation of how *a priori* knowledge of (3) is possible, in a way that no appeal to (2) could do. I have *a priori* knowledge of (3) in virtue of grasping rule (1), or some analogous rule in another language.

In short, EM generates a new account of aprioricity as analyticity, because it postulates introduction and elimination rules at the cognitive-role level. Indisputably, this is important and new – a major twentieth-century contribution to philosophy. But is it right? *Does* the aprioricity of (3) depend in any way on there being a rule of English expressible by (1), or some analogous rule for another language? Well, it's far from obvious that it does depend on that. Do we want to say that (3) is '*a priori*'? What makes us want to say it is, if we do, does not seem to stem from the fact that some language, English or another, contains some rule. Rather, the essential point is simply that we converge, on critical reflection, in finding (3) primitively or spontaneously compelling. It is a fundamental epistemic norm: it expresses a primitive normative response. Acknowledging it does not consist in learning any linguistic convention or stipulation. It's the other way round: training in linguistic conventions *assumes* such primitive normative responses. In teaching (2) we assume the existence of belief-forming dispositions responsive to (3). And once a person had learned (2) he or she would see the truth of (1), understood now not as a language rule but as a consequence of (2) and (3).

On the other hand, we have accepted the point that no fact is intrinsically normative. So acknowledging (3) does not consist in knowledge of any fact, natural or non-natural. What, then, is its epistemology? As for any other fundamental norm, be it of belief, action, or feeling, it is the epistemology of reflective examination and critical convergence. That is the epistemology characteristic of the normative: it is not the epistemology appropriate to propositions which depict the existence of a state of affairs.

This takes us to the brink of controversial epistemological questions which are not on our agenda here. For present purposes it is enough to pin down how EC, the view that concepts are patterns of epistemic norms, differs from EM, the view that they are patterns of language-rules. EC requires the thesis that the normative and the factual are both domains of judgment, consisting of propositions with truth-value. If this is defensible, then we can say that (3) expresses a norm partially constitutive of the concept *yellow*. We can also say it is a 'conceptual truth' – at any rate it is concept-constituting and it is true. *But its status as a conceptual truth in this sense in no way explains how it might be* a priori. The way it is known to be true is the way that any fundamental norm is known to be true; its epistemology is that appropriate to fundamental norms in general. It is not *because* it is a conceptual truth, constitutive of the concept *yellow*, that it is true. Thus EC does not belong to that class of views which takes certain truths to be '*a priori*' and seeks to *explain* that status by saying that they are conceptual (truths, that is, which go beyond the Kant/Mill prototype of analyticity). But this does not matter. If concepts are constituted by norms of reasoning, and if we can get a satisfactory account of normative knowledge, we do not *also* need a substantive theory of the *a priori* which goes beyond Kant/Mill analyticity. An account of normative knowledge will do what an account of the *a priori* was meant to do.[28]

I assumed earlier (§3.1) that Wittgenstein is neither a nihilist nor a radical conventionalist nor a reductionist about rule-following. If all this is right then the later Wittgenstein needs a distinction between rules and norms of the kind made here. His own reflections on rule-following show that to avoid this trilemma one must go beyond the Viennese dichotomy of facts and rules. It is that dichotomy, together with the points that no object has intrinsic meaning and no fact is intrinsically normative, that produces the package of EM, the linguistic theory of the *a priori*, and radical conventionalism about logic and rule-following. But did Wittgenstein go beyond it? Reading his later writings on 'grammar' and 'rules' it is hard to come up with an answer. Michael Dummett attributes the whole package to Wittgenstein (see, e.g., Dummett, 1959a, 1994; cp. Stroud, 1965). Others disagree. They faithfully reflect Wittgenstein's own murkiness. In a valuable discussion of Wittgenstein's notion of a criterion, for example, Hacker (1990) comments thus:

> To say that *q* is a criterion for W is to give a partial explanation of the meaning of 'W,' and in that sense to give a rule for its correct use. The fact that the criterial relation between *q* and W may be neither arbitrary (in one sense at least) nor stipulated, that in innumerable cases we could not resolve to abandon the normative relationship without a change in our form of life, and in many cases could not abandon it at all, does not imply that it is empirical, let alone that it is a matter of *Wesensschau*. We may concede that certain concepts are deeply embedded in our lives, occupy a pivotal role in our thought and experience, yet still insist that their use is rule-governed, a matter of *nomos* rather than *phusis*. (p. 552)

Note how the line of thought here goes from acknowledging that the relationship is 'normative' to the conclusion that – however inescapable for us, however felt as a constraint rather than a stipulation – it must yet be a 'rule,' a matter of convention rather than nature. But why cannot it be acknowledged that it is normative without being in *any*

sense a convention? It is hard to see what could be at work here other than the philosophical thesis that all propositions, judgable contents, are factual.

It may be impossible to tell how far Wittgenstein thought his way past this thesis. On the one hand, he was not (in his later thought) burdened by the realist semantic assumptions about truth and reference which lead to it. But on the other hand, his constant insistence that 'training' determines the 'logical grammar,' or framework, of our language-games at least suggests that he did not repudiate the Viennese dichotomy of facts and rules. For one is 'trained' to observe rules: the process of acknowledging a norm – spontaneously, autonomously – is a process of education, not 'training.'

At any rate, if we reject the thesis that all judgable content is factual, we can acknowledge that the normative is a domain of the understanding, something we judge of – but yet that norms are still like rules in this respect: we do not find them in the world. They are presupposed in cognition of a world – and that view still has certain strong affinities with Wittgenstein's later philosophy, even if it is not his. For example, what he says about logic would also apply to this view of norms. For them, as for 'logic,'

> There is not any question at all … of some correspondence between what is said and reality; rather is logic antecedent to any such correspondence. (Wittgenstein, 1978, l.156, 96)

Certainly this a very important and controversial philosophical claim. The question in the end, of course, is not who thought it but whether it is true, and if so, how or why.

Notes

1 I am grateful to Bob Hale and Crispin Wright for many very useful discussions (including some illuminating disagreements) about the issues dealt with in this chapter. The points made in §3 are developed more fully in Skorupski (2010).

2 I shall refer to its development in Wittgenstein's thought, since his discussions of it remain influential and exemplary. A balanced historical account would also examine the important ideas of a number of his contemporaries; for example, Rudolf Carnap and Moritz Schlick in the development of Viennese verificationism and Friedrich Waismann for his influence on the development of ordinary language philosophy (e.g., Carnap, 1936; 1937; 1949; 1967; Schlick, 1936; 1979, vol. 2; Waismann, 1945; Wittgenstein, 1979).

3 In the *Tractatus* (Wittgenstein, 1961, 6. 211) he merely notes, "In philosophy the question, 'What do we actually use this word or this proposition for?' repeatedly leads to valuable insights."

The characterization of a word's meaning as its use in a language becomes prominent in his conversations with Schlick and others between 1929 and 1932 and in lectures and writing of the 1930s. For example, in *Philosophical Grammar* (Wittgenstein, 1974): "We ask 'How do you use the word, what do you do with it' – that will tell us how you understand it" (p. 87); "The use of a word in the language is its meaning … Grammar describes the use of words in the language" (p. 60). Further, description of use is description of *rules* of use, like description of 'rules of a game': "'I can use the word *yellow*' is like 'I know how to move the king in chess'" (p. 49). Wittgenstein retains this conception even when he drops his verificationism (on which see §2.1).

4 '[T]he meaning of a word is what the explanation of its meaning explains … "What 1 c.c. of water weighs is called '1 gram' – Well, what *does* it weigh?" … Meaning, in our sense, is embodied in the explanation of meaning' (Wittgenstein, 1974, pp. 59–60).

5 You need to know this basic principle to lie (to seek to make someone believe something is true which you know to be false, by asserting it).

6 "It is what is regarded as the justification of an assertion that constitutes the sense of the assertion" (Wittgenstein, 1974, p. 81).

7 Here I use 'semantics' broadly, as equivalent to 'theory of meaning' (or if the term 'meaning' is resisted, of 'language use'). In this broad sense it is not distinguished from syntax but includes it.

8 I borrow the name from Michael Dummett (e.g., Dummett, 1993c, ch. 2), but the account of the idea in what follows is my own.

9 EM should also be distinguished from conceptual role semantics (see Field, 1977, and Peacocke, 1981 and ed. 1993, for a selection of representative articles). They often sound similar, and similar issues, for example about reference and truth, arise for them. The difference is that EM describes understanding in terms of grasp of rules, while conceptual role semantics describes it solely in terms of assertoric and inferential dispositions. The difference disappears if grasp of rules reduces to assertoric and inferential dispositions – whether or not it does is *one* of the issues at stake in the rule-following considerations (see Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING).

10 What is abolished is the idea of epistemology as the study of norms of belief, understood as distinct from linguistic conventions or proposals. 'Epistemology' can still remain as the name for conceptual analysis of what kind of fact is asserted to hold when one says, for example, that a person *knows* that so-and-so is the case.

11 Warrant, incidentally, comes in degrees. That is important, and a comprehensive theory would need to take it into account. However, it will not be considered here.

12 It may mention them in giving truth-conditions for sentences which themselves mention concepts and propositions. But while this might show that they enter its ontology, it would not show that it makes explanatory appeal to them in exhibiting what language-understanding is.

13 This attempt to show that truth-conditional semantics is consistent with the priority thesis is loosely based on earlier discussions by Davidson and others of the philosophy underlying his program for semantics. See Davidson (1984); Evans and McDowell (1976), 'Introduction,' and Davidson's reply to Foster therein.

14 This line of thought implies either (a) a 'deflationary,' 'redundancy,' or 'minimalist' theory of truth (a theory of the kind discussed, e.g., in Horwich, 1990) or (b) a verificationist theory of truth (see §2.1). So the disjunction of (a) and (b) *follows* from the priority thesis. A separate issue is whether a truth-conditional theory which clear-headedly *rejects* the priority thesis has to adopt some theory of truth more robust than (a) (including (b) among these more robust theories). Some argue that it does have to do so (see Peacocke, 1993b, xvi); I do not myself think that is so.

15 Remember that we are talking here of a *normative* response: there is no attempt in this account of understanding to reduce or eliminate normative attitudes to language use.

16 Contemporary philosophers who have influentially espoused a view of truth like this include Putnam (1990) and Wright; but Wright now accepts it only for some areas of discourse – see his concept of 'superassertibility' in Wright (1992). Interestingly, it is not prominent in either Wittgenstein or the Vienna Circle. Schlick is closest to it. Neurath inclined to coherentism or to questioning the very respectability of the concept of truth; Carnap (1949), relying on Tarski's semantic characterization of truth, defended truth as a respectable concept but explicitly distinguished it from assertibility. Wittgenstein inclined to a deflationary view of it. As remarked in n. 14, both the verificationist and the deflationary view are consistent with the priority thesis.

17 This passage comes from a section copied by Stein from notes which Waismann circulated as a transcript of Wittgenstein's views (see editor's introduction to Wittgenstein, 1979, p. 20).

18 "The direction of a thought-movement is defined by the logical place of the answer." Note the continuity with *Tractatus* 6.5 and 6.51; cp. Wittgenstein (1975, pp. 66 and 174): 'The meaning of a question is the method of answering it,' and 'Every proposition is the signpost for a verification.'

19 In Waismann's own theses (included in Wittgenstein, 1979, as Appendix B) the 'positivistic' kind of verificationism is rather more prominent – "To understand a proposition means to know how things stand if the proposition is true" – but the operationist conception is simultaneously stressed.

20 The suggestion is canvassed by Crispin Wright in "Anti-realism and revisionism," *Realism, Meaning and Truth*, pp. 317–341. Cp. Skorupski (1988, §VI, pp. 516–523).

21 Further discussion of related issues, together with further reading, can be found in Wright (1987, pp. 309–316: "Could Thatcher be a master-criminal?"). Note, however, that Wright's discussion is about the implications for an 'epistemically constrained' notion of truth, whereas here the issue concerns EM and its account of the meaning of logical operators.

22 In this section I have skirted obscure and much-discussed issues about 'holism,' 'anti-realism,' and classical logic. A statement of Dummett's view (which is opposed to that taken here) is Dummett (1991, chs 8–12). Compare Wright, "Anti-realism," §VI in Wright (1987). The line I have taken is discussed a little more extensively in §§I–VII of Skorupski (1993a).

23 "What else but a fact can a statement express? In what sense could something be called 'true' or 'false' if it does not designate an existing or nonexisting fact?" (Carnap, 1967, p. 341).

24 It does not correspond to the fact that the patch is yellow. Rather, the English sentence 'The patch is yellow' can express a fact because the normative proposition 'If you're following the rules of English you ought to call this patch "yellow"' can be determinately true.

25 Two writers who argue for an epistemic theory of content – though in quite different and, indeed, unrelated ways – are John Pollock and Christopher Peacocke. Peacocke's theory has been developed in a number of writings, most recently at book length in Peacocke (1992). An accessible account of Pollock's view is in Pollock (1987). Also, those writers in the Davidsonian truth-conditional tradition who hold that interpreting the meaning of a speaker's utterances requires that one attribute norms of rationality to the speaker, in effect yoke a truth-conditional semantics to an epistemic theory of content. See Davidson (1984).

26 For further discussion of these matters see Coffa (1991) and Skorupski (1993b). See also Chapter 23, ANALYTICITY.

27 The dispute goes right back to the Vienna Circle. Neurath announced that "*Statements are compared with statements*, not with 'experiences,' 'the world,' or anything else" (Neurath, 1959, p. 291). Schlick replied: "It is my humble opinion that we can compare anything to anything if we choose" (Schlick, 1979, vol. 2, p. 401). See Jacob (1984). A non-linguistic version of the Neurathian doctrine is that only a belief can provide a reason for a belief: see, e.g., Davidson (1986). For recent discussions of how experience provides reasons for belief see McDowell (1994) and Millar (1991).

28 Peacocke argues that a theory of concepts cast in terms of norms of reasoning can yield a substantive account of the *a priori* which differs from the EM account of analyticity discussed in this section. His account does not seem to me to be successful, but neither does it seem to me to be needed for his project of stating possession conditions for concepts. See Peacocke (1993a), Skorupski (1995), and Peacocke (1996).

Postscript

BERNHARD WEISS

John Skorupski's chapter leads us from broad ideas about meaning as being constituted by use to the verificationist conception of meaning (§2). The verificationist account takes it that we can characterize the meaning of a sentence in terms of the conditions warranting its assertion. However, as Skorupski notes, this conception seems to face insurmountable obstacles. And thus we are led 'beyond verificationism' (§2.3). Here I reprise these difficulties for verificationism and look at recent attempts to respond to them within the 'meaning as use' paradigm. I end with a brief review of recent discussion of Fitch's paradox, which appears to challenge, what is often taken to be a consequence of a use-conception of meaning, verificationism about truth.

Meaning Is Use

It's very easy to agree with the slogan "meaning is use" simply because words don't select their own meanings. Words, as shapes or sounds, are intrinsically meaningless and acquire meanings on being put to a multitude of uses by speakers; we, speakers, confer meanings on our words by *using* them, in context, in the ways that we do. And differences in the use of words go along with differences in their meaning. But historically the slogan has been espoused with more positive intent than just this.

The slogan can acquire more substance either by linking it to a methodological approach or to explanatory ambitions. Methodologically, we might find ourselves being told to clarify the meaning of a word by attending to how it is used; and, since the meaning of a word is a concept, we might clarify concepts by attending to the use of words. Philosophical problems often (perhaps always) require a reflective appreciation of certain elusive concepts. We can thus partially approach those problems by focusing on the use of certain vital words which express them. Moreover, one might argue that philosophical problems *only* require reflective appreciation of the nature of concepts in order to be solved or dissolved. So, one might claim, philosophical problems are dealt with by examining the use of words. Claims of this ilk are distinctive of ordinary language philosophy, and, on some readings of the later Wittgenstein, form at least part of his conception of philosophical method. I won't be discussing these approaches here; rather I want to consider meaning as use when considered in connection with explanatory ambitions.

One might accept the close connection between use and meaning but treat it simply as a *constraint* on an account of meaning. In other words, we could simply treat the observation as a way of testing the adequacy of any explanation of meaning: a difference in use should go along with a difference in the explanation of meaning. But the explanation of meaning might focus on properties of signs which differ from use, such as their relations to non-linguistic entities. Accounts of this form might be termed truth-conditional or representational theories of meaning and are described elsewhere in this volume (see Chapter 2, MEANING AND TRUTH-CONDITIONS: FROM FREGE'S GRAND DESIGN TO DAVIDSON'S, and Chapter 4, MEANING, USE, VERIFICATION, §1.4). Though I'll return to these accounts later, let us now simply note that accounts which take the semantic concepts as explanatorily basic count as rejections of the *meaning as use* slogan, since meaning is explained in terms of properties other than use.

In contrast, to adhere to the meaning as use slogan, construed in the explanatory vein, is to attempt to account for meaning in terms of properties of use. Taking it that meaning *is* use, the aim of the theorist of meaning is systematically to characterize the use of all expressions in a natural language.

Use and Assertion

Words have only one kind of use: they are employed in sentences. But sentences come in a range of moods which are used in performing a range of speech acts. In one way or another meaning as use theorists privilege the role of assertion. Historically, this may be a hangover from the truth-conditional approach or may be a product of the fact that some use-theoretic accounts are attempts to generalize the approach from mathematics to the rest of language. These historical reasons are not nugatory. The reasons for focusing on truth are often good reasons for focusing on assertion, and, whatever account is settled on for language as a whole, will have to apply to the special region of mathematical language too. So, for instance, it's hard to see how commands could occupy the same role as do assertions, since it is hard to see some contents as being fit to be commanded – content about mathematical matter, but others too – and hard to see how to account for the fulfilment conditions of commands except in terms of the truth-conditions (or meaning) of corresponding assertions.

So (as Skorupski notes (§1.3)) central to use-theoretic accounts is the attempt to explain assertion conditions. As I've hinted, the approach has a provenance in the philosophy of mathematics, where the aim is to characterize the proof-conditions of a complex sentence

in terms of those of its components. It's worth pausing briefly to consider the mathematical case, if only to salvage a sense of the problems that attend the attempt to generalize it. So, for example, intuitionists in the philosophy of mathematics put forward clauses in the following style:

A proof of P ∨ Q is a construction which recognizably yields a proof of P or a proof of Q.

The clause explains what it is for a construction to be a proof of a complex sentence in terms of what it is to be a proof of its components. Anyone who understands the full gamut of clauses is able to recognize whether or not a presented construction is or is not a proof of a given sentence. And, knowing the epistemological significance of *proof*, this feeds directly into her use of the sentence in terms of whether or not she is prepared to assert it. Truth plays no explanatory role in the account; so we might be deflationists about truth but we might instead identify truth with provability: a sentence is true iff it is provable. This question will hinge on other commitments.

The reason we can identify truth with provability is that proof is indefeasible in the following sense. Take the two sentences P and 'It is provable that P,' and suppose each is assertible. Imagine now that we learn something which we legitimately take to undermine the assertibility of the one. Then the assertibility of the other is likewise undermined. This is a major difference between proof in mathematics and any plausible notion of warranted assertibility applicable to empirical discourse.

This fact generates the following problem.[1] Take the supposition that the meaning (or the meaning-determining uses) of a sentence are captured by stating its conditions of warranted assertion.

It is clear then that the sentences P and 'It is warrantedly assertible that P' share the same conditions of warranted assertibility: if one is warrantedly assertible so is the other. But the two sentences embed differently in complex sentences and thus have different meanings. To take an example, the following sentence is almost certainly true:

If there will be no rain this season then the crops will fail.

Yet the following sentence may well not be true:

If it is warrantedly assertible that there will be no rain this season then the crops will fail.

The reason we might have these different reactions to the conditional is that there is a difference between the statements expressed by (simultaneous) utterances of 'There will be no rain this season' and 'It is warrantedly assertible that there will be no rain this season.' The former may turn out to be false when it turns rainy, yet the latter remain true: the epistemic situation, as it then was, did indeed warrant the assertion; and contrariwise the former may be true when it stays dry, yet there is no good warrant for the assertion. This doesn't, however, solve the problem; it merely gives us a description of it, since talking about the statement expressed by an assertion presupposes an appreciation of its meaning. What we need is to latch onto conditions of use which enable us to mark this distinction in meaning.

There are two broad approaches to the problem. The first is to try to find a use-condition which mimics the indefeasibility of mathematical proof; the other is to complicate the set of use-conditions that we invoke in explaining meaning. Let's look at each approach in turn.

A First Response: Specialized Assertion Conditions

The first approach might be pursued by idealizing one's epistemic situation. So Peirce suggests that we think, not of what is currently assertible at our imperfect stage of enquiry, but of what is assertible at the end of enquiry. At that stage, by hypothesis, we contemplate no further amplification of enquirers' body of information and thus defeat of a statement assertible at the end of enquiry is impossible. And Putnam (1981) suggests that we focus on the ideal justification of a statement. Both of these proposals are problematic: Peirce's because it is far from evident that there is a single stage of enquiry which will simultaneously be epistemically perfect for every statement; and Putnam's because of difficulties in articulating what would be an ideal justification. In addition, both proposals appear to be susceptible to a version of the conditional fallacy. On the Peircian account we might have "P iff (if C were to obtain then it would be assertible that P)," where C are ideal conditions. But then letting P be 'C will never obtain' we arrive at: "C will never obtain iff (if C were to obtain then it would be assertible that C will never obtain)," which is patently unacceptable. Putnam seems to be in a better position because his ideal conditions, C, vary from one proposition to another. But this only helps if it can be guaranteed that for all propositions, P, the ideal conditions for judging that P obtains differ from the ideal conditions for judging that P's ideal conditions obtain. If not, we can form a restricted version of the very same problem (see Plantinga, 1982, and Wright, 2000). On Putnam's account we have:

> P iff (if conditions were to be C(P) then P would be assertible)

Let P = C(P)will never obtain

> C(P) will never obtain iff (if conditions were to be C(C(P))then it would be assertible that C(P) never obtain)

Suppose C(C(P)) = C(P) and we infer:

> C(P) will never obtain iff (if conditions were to be C(P) then it would be assertible that C(P) never obtain)

And this, as before, is unacceptable.

Finally, because these are ideal conditions which may not be humanly feasible to achieve, it is doubtful that they happily unpack a notion of use-conditions (see Skorupski, §2.1; Moore, 2012; and Williamson, 2006).

In response to these problems Wright suggests that we don't idealize conditions of assertion; rather we focus on actual conditions of warranted assertion but envisage the properties of the assertion to be suitably ideal. So he invents the notion of superassertibility: a statement is superassertible when it is warrantedly assertible and warrant for its assertion will, in fact, survive future investigation no matter how strenuous. Superassertible statements are, like proven statements in mathematics, enduringly warrantedly assertible. But Wright's account is not without difficulties: one is that *types* of sentences don't have superassertibility conditions, since the same type of condition may be a superassertion condition in one circumstance – since *in fact* it cannot be defeated on further investigation – but not in another – since in these circumstances it is *in fact* capable of defeat. But surely, in understanding a language, what speakers learn is the meaning of types of sentences[2] and

thus what the theory of meaning should aim, primarily, to detail are the meanings of types of sentences. Superassertion conditions seem ill-fitted to this role.

Before moving to the other broad category of approaches it is worth observing that one perhaps ought to read the above accounts as offering analyses of truth in epistemological terms and then employing the epistemic conception of truth in a truth-conditional account of meaning. Indeed, Peirce advances his account as a view of truth, as does Putnam; and Wright not only suggests that we view superassertibility as an epistemic conception of truth but sketches a truth-conditional theory of meaning in Davidsonian style taking this as the operative notion of truth (Wright, 1993, essay 14). So here we bring together representationalism about meaning with meaning as use, through verificationism about truth.[3]

A Second Response: Adding to Assertion Conditions

The second broad set of approaches complicates the set of uses which are taken to determine meaning. Though there are a number of flavors to choose from, all the options look beyond mere assertion conditions to another set of use-conditions. Some proposals appeal to two well-defined sets of conditions; for example some argue in favor of using both assertion and denial conditions[4]; others suggest assertion and retraction conditions (Weiss, 2007; Edgington, 1981); and Brandom situates meaning in a complex normative practice whose basic normative statuses are the commitments and entitlements which accrue as a result of making a move in the practice (see Brandom, 1994; 2000). Others simply choose a more indefinitely specified set of use-conditions. Cozzo and Horwich[5] both focus on characterizing the meaning of words through aspects of their use, Cozzo invoking the word's 'immediate argumental role' (Cozzo, 1994) and Horwich the word's acceptance conditions.[6] In either case we consider a range of such use-conditions which suffice to explain the word's overall use; and, of course, it is an assumption of the approaches that some such set of uses will indeed be explanatorily sufficient.[7]

On all these approaches meanings involve marrying sets of conditions, for instance, marrying assertion with denial conditions. And there is a degree of freedom in how meanings bring about this marriage, since, were we able to derive the one set of conditions from the other, these would not be distinct. Some treat this as a promising feature of the approach, others as problematic. Dummett[8] has long argued against what we might call multilateral[9] approaches precisely on these grounds because he thinks that we might then have a situation in which an assertion is neither correct – since its assertion conditions are not fulfilled – nor incorrect – since its denial conditions are not fulfilled; yet it is absurd to suppose that the act of assertion might have this kind of indeterminate outcome.[10] But even Dummett concedes that, if we are to account for language as it is actually used, we may need to adopt a multilateral approach (see Dummett, 2010, p. 226). Thus it seems the basis of his view is a sense that any such language is logically objectionable because it incorporates substantial presuppositions about the world. And indeed, most advocates of multilateralism accept this,[11] but tend to treat it is an advantage of use-conditional accounts over truth-conditional accounts.[12]

Fitch's Paradox or the Paradox of Knowability

I turn now to truth. The view that truth amounts to some conception of verifiability is challenged by Fitch's paradox (Fitch, 1961). Fitch's reasoning seems to show that the following is a theorem: $(\forall p)(p \rightarrow \Diamond Kp) \rightarrow (\forall p)(p \rightarrow Kp)$. And this appears to be absurd: from the claim

that any truth is knowable – by no means evidently absurd – we infer the absurd claim that every truth is known. This is certainly a problem for anyone advocating the claim that every truth is knowable but is also a problem for anyone who thinks, as most do, that knowability falls short of being known (see Brogaard and Salerno, 2007). In essence, the paradox asks us to rescue from obvious falsehood the philosophical position that truth coincides with verifiability.

I won't present the reasoning formally here. The crux of the argument is to take the proposition $q \wedge \neg Kq$ and to assume it to be true. If every truth is knowable it follows that $\Diamond K(q \wedge \neg Kq)$. But using the seemingly uncontroversial principles that knowledge is factive and that if a conjunction is known then each conjunct is known (together with weak modal principles: necessitation and closure of possibility under strict implication) we then infer that a contradiction $Kq \wedge \neg Kq$ is possible, which is, of course absurd.

Our options are as follows:

1. To reject the modal and epistemic principles involved.
2. To reject the methods of reasoning involved.
3. To reinterpret the original claim: $(\forall p)(p \rightarrow \Diamond Kp)$.

Remarks on each option:

1. The problem with rejecting the modal principles is that they are very weak. Necessitation and the closure of possibility under strict implication are principles of the weakest of modal systems, K. The epistemic principles seem equally undeniable; the incompatibility of knowing a claim with that claim's falsity is highly plausible and (given classical logic) entails that knowledge is factive. And it is hard to see how one could know a conjunction without knowing each conjunct.
2. One might reject the reasoning involved by, say, eschewing classical in favor of intuitionistic logic. But intuitionistically we would be able to infer $\neg Kp \rightarrow \neg p$, which seems equally problematic.
3. We might reinterpret the original claim. Reinterpretative strategies come in the following forms:
   a. Restriction of the quantifier: (e.g., Dummett, 2001; Tennant, 2002).
   b. Reinterpretation of the conditional and/or negation: (e.g., Dummett, 2007; de Vidi and Solomon, 2001; Williamson, 1982).
   c. Reinterpretation of the '$\Diamond$': e.g., Pragmatic versus Semantic impossibilities (e.g., Hand, 2009).
   d. Reinterpretation of 'K': e.g., Conjunctive Knowability (Restall, 2009); Recognizing the truth-conferring state of affairs (Jenkins, 2009); Non-actual knowers (Edgington, 1985).

   Reinterpretation is obviously only of service if it can be shown where, on the reinterpretation, the Fitch reasoning fails and that, once reinterpreted, the knowability principle can be squared with a plausible understanding of the claim that every truth is knowable.

Notes

1 See Brandom (1976); Dummett (1981), where he contrasts content with ingredient sense; and Wright, 1993. Skorupski points out the problem at §2.3. For a more recent debate see Casalegno (2002), Wright (2012), and Williamson (2012a; 2012b). Dummett (2002a) draws attention to the phenomenon and, interestingly, uses it *against* truth-conditional accounts of meaning.

2 Or better, what they learn is the meaning of words, which yields grasp of the meanings of types of sentences.
3 See discussion of Fitch's paradox below.
4 Rumfitt (2000) and Price (1983). For response see Dummett (2002b).
5 While most use-conditional theorists conceive of use in normative terms, interpreting conditions of use as akin to *rules* for use, Horwich is an exception and derives his acceptance properties of words from regularities of their use.
6 Horwich (1998). In this vein see also Peregrin (1995; 2006).
7 The approach can be seen to be a generalization of proof-theoretic or inferentialist approaches to the meanings of the logical connectives. Here the debate has an additional dimension in accounting not only for the meaning of the logical constants but also for the epistemology of inference. See: Boghossian (2003) and (2012); Williamson (2003; 2012a); Casalegno (2004); Peregrin (2010); Brandom (2008); Read (2004); Dummett (1991); Restall (2005), Tennant (2005).
8 A good example is his (2002a) response to Rumfitt.
9 Following Rumfitt (2000).
10 See Rumfitt (2000) and Price (1983) for rebuttals of this objection. It is also not evident that other approaches, such as marrying assertion with defeating conditions, lead to this problem.
11 Cozzo thus speaks about the "correctness of a language"; Brandom speaks about inferences which are incorporated in moving from an assertion's grounds to its consequences, and notes that these ought to be actually materially good but need not be formally good; Horwich notes the existential presupposition in some sets of acceptance conditions.
12 Terms which are, for instance, pejorative might have meanings which certain speakers find objectionable. The orthodox truth-conditional account can allow for this by relegating this to a feature of meaning irrelevant to semantic evaluation, such as Fregean color or tone; but the phenomenon discussed in the text cannot be relegated to the non-semantic in this way.

Semantics and Pragmatics

GUY LONGWORTH[1]

1 Pragmatics and Semantics

We use language in order to achieve a wide variety of ends. To a good first approximation, pragmatics is the study of the things we do in, or by, using language, together with the facts, knowledge, and abilities that we exploit in order to do those things. Correlatively, pragmatic phenomena are all and only the phenomena that are studied in doing pragmatics. In using bits of language in order to achieve our ends, we rely on various facts about those bits of language, together with knowledge and abilities relating to those facts. For one prominent example, we exploit facts about the meanings of the words that we use, and facts about the meanings of sentences that depend upon the combination of words in them given those words' meanings. To a good first approximation, semantics is the study of facts about the meanings of words and sentences, about the dependence of sentence meaning on combinations of word meanings, and about our knowledge and abilities relating to those facts. Correlatively, semantic phenomena are all and only those phenomena studied in doing semantics. There is no obvious reason, in advance of further inquiry, to suppose that no phenomena fall within the remits of both semantics and pragmatics, and some reason to think that many phenomena fall within both. For example, it is natural to assume that speakers' knowledge of meaning will figure in shaping their use of language, and in the reception of that use. And many philosophers have held that the use of language plays a constitutive role in determining the standing meanings of the words that are so used. However, some theorists appeal to a more restrictive conception of pragmatics – roughly, pragmatics minus semantics – and thereby to force a sort of partition. Nothing turns on this.

(The label "pragmatics" derives from the Greek root "pragma," meaning *deed*. The earliest relevant occurrence in the *Oxford English Dictionary* for the study of practical aspects of human action and thought is the 1693 title of a book by E. Settle, *The new Athenian comedy containing the politicks, oeconomicks, theologicks, poeticks, mathematicks, sophisticks, pragmaticks, dogmaticks, &c. of that most learned society*. The label "semantics" derives from the

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

Greek roots "sēma," meaning *sign*, or "sēmantikos," meaning *significant*. The earliest relevant occurrence in the *Oxford English Dictionary*, for that which relates to divination through the interpretation of signs, is from 1665, in John Spencer's *A discourse concerning prodigies* (2nd edn, London: printed by F. Field for W. Graves). Contemporary uses of the labels seem to derive, more or less loosely, from work by Charles Morris in the 1930s, culminating in his (1938). But we shouldn't get too hung up about labels. Useful discussions of various ways of distinguishing between semantics and pragmatics may be found in Bach, 1999, and Szabó, 2006.)

In addition to getting on with the projects of pragmatics and semantics – that is, theorizing about things done with words and about some of the properties of words that figure in doing those things – philosophers and linguists have been concerned to say more about the natures of the two projects, the range of phenomena that fall within each, and the connections between the projects and the phenomena that each aim to treat. As Dorothy Edgington puts it,

> At its most general, the issue here is how much of our ability to communicate rests on specifically linguistic knowledge, and how large a role is played by background knowledge, common sense and inference to the best explanation, all of which play a role in the pragmatics of communication. (Edgington, 2006, p. 769)

Of central importance here have been two related questions.

The first question concerns one type of thing that people do with language and that seems to depend heavily on the meanings of the words that they use: stating or asserting things. (I'll treat stating and asserting as the same activity.) Philosophers care about what people state, and the circumstances in which they state those things, for various reasons, but in particular because of the way that the things people state figure in revealing their commitments, including their beliefs. (That is not to say that what one commits to in speaking, or in stating what one does, is to be identified with that which one says. We might say things without thereby committing ourselves, for instance in speaking ironically. And we might commit ourselves to things that we do not say or state, for instance in stating things that entail further commitments.) The first question is whether facts about what people state – for example, the fact that Bill stated that Jill smokes – are to be accounted for within semantics or pragmatics. Are the facts about what people state determined solely by the meanings of the words they use – so that they fall within the remit of semantics? Or are facts about what people state dependent also on general facts about what they are up to, the circumstances in which they speak, and so forth – so that they fall partly within the remit of pragmatics?

The second question concerns a specific mode of evaluation or description of people's actions, or of the commitments embodied in those actions: evaluation or description as to truth. We often evaluate or describe what people state, as well as what they believe, as being true or false. For instance, Bill stated that Jill smokes. But Jill doesn't smoke. So what Bill stated is false. Philosophers care about this mode of evaluation in part because it figures in wider assessments of what people do: for one artificial example, if we suppose that it is wrong to state things that are false, then the fact that what Bill stated is false entails that it was wrong of Bill to state it. In addition, philosophers care about the conditions in which one or another evaluation of that sort is mandated, the conditions in which what someone is committed to would be true or false. Bill stated that Jill smokes. How would the world need to be in order for what Bill stated to be true? How would it need to be for what he stated to be false?

In learning answers to those questions, we might learn something about what it is for someone to smoke. And so, *mutatis mutandis*, for topics of more pressing philosophical interest: the conditions in which stating that Bill *knows* that Jill smokes would be stating something true or false; the conditions in which stating that it is *wrong* for Jill to smoke would be stating something true or false; and so forth. The second question is whether facts about the conditions in which what someone states would be true or false are to be accounted for within semantics or pragmatics. Are the facts about the conditions in which what someone states would be true or false determined solely by the meanings of the words they use – so that those facts fall within the remit of semantics? Even if they are not, it may be that the meaning of a sentence determines its truth-conditions, so that it is possible to assess sentences as true or false independently of what speakers state by the use of those sentences. Alternatively, facts about truth-conditions may be dependent also on general facts about what speakers are up to, the circumstances in which they speak, and so forth – so that those facts fall within the remit of pragmatics. Crucially, it will be possible to account for sentence meaning by appeal to truth-conditions, or by appeal to propositions that determine truth-conditions, only in so far as meaning determines truth-conditions. (See Wiggins, Chapter 2, MEANING AND TRUTH-CONDITIONS: FROM FREGE'S GRAND DESIGN TO DAVIDSON'S.)

In order to discuss those issues, we will need to spend some time developing the orthodox contemporary position on these matters, which derives from the work of Paul Grice (§§3–5). And it will facilitate our understanding of Grice to start a little further back, with the types of position to which Grice was responding, and an initial response to those types of view, due to J. L. Austin, that Grice sought to develop in his own work (§§2–3). Having developed the orthodox view, we'll then consider one source of opposition to the view, due to Charles Travis, and see how it leads to an alternative view (§§6–7).

2 Austin on Locutionary, Illocutionary, and Perlocutionary Acts

Contemporary recognition of the importance of divisions amongst pragmatic and semantic phenomena has its roots in earlier recognition of the importance of pragmatic phenomena. By the middle of the twentieth century, philosophers had begun to emphasize the importance of attention to language use in theorizing about language, including attention to the things speakers achieve, or aim to achieve, by saying what they do. In itself, the emphasis on use seems admirable, and is preserved in more recent theorizing about language. However, it was common during this period for philosophers to overplay the connection between meaning and use. Gripped by the importance of attention to the use of language, some philosophers went so far as to claim that meaning is determined by, and fully explains, use – in its most plausible formulations, that the meanings of many words are determined by the uses of sentences involving those words. More generally, a number of philosophers had assumed that appeals to meaning would underwrite direct explanations of use, so that it would be comparatively straightforward to discern features of the meanings of words from features of the uses of those words. (Such an assumption arguably figures in work of this period by R. M. Hare, Norman Malcolm, G. E. Moore, Gilbert Ryle, P. F. Strawson, and Ludwig Wittgenstein, amongst others.) Attempts to distinguish meaning from use, and to draw distinctions amongst types of uses of language, emerged in reaction to such assimilations of meaning and use. (See Soames, 2003, pp. 65–219.)

While it is surely true that the meanings of words play an explanatory role in many of the things that we do with those words, that bromide leaves open that the explanation of language use may have many other moving parts and that, as a consequence, the connection between meaning and use might be quite indirect. Moreover, it leaves open that the use of language might be many-faceted, and that meaning might play different roles – and more or less direct roles – in explaining different facets of use. Recognition of both points figured in the articulation of distinctions between semantic and pragmatic phenomena as well as distinctions amongst the pragmatic phenomena that meaning figures in explaining. (It is perhaps worth observing that many philosophers during this period had a more general tendency to assume that explanatory connections would be direct. For example, many philosophers during this period were sympathetic to the ideas that aspects of mind are directly expressed in behavior and that the cognitive content of scientific theories might be determined in a simple way by the pattern of observations taken to support those theories. So, the recognition of a need to allow for greater theoretical distance between meaning and various facets of use is of a piece with a more general cognizance of the potential indirectness of explanatory connections.)

J. L. Austin played an important role in directing attention onto some of the required distinctions. In particular, he sketched a distinction amongst three types of thing a speaker might do in using a sentence – that is, amongst three types of act a speaker might perform by speaking as they do:

> *The locutionary act*: the production of an utterance that can be classified by its phonetic, grammatical, and lexical characteristics, up to sentence meaning (the *phatic* act). It is also the performance of an act that can be classified by its *content* (the *rhetic* act) – a feature distinctively of acts of speech. If I promise *that I'll be home for dinner* and then promise *that I'll work late*, my actions are instances of two different locutionary acts: one with the content that I'll be home for dinner, and one with the content that I'll work late. (Austin, 1962b, pp. 94–98)
>
> *The illocutionary act*: an act classifiable not only by its content – as with the locutionary act – but also by its *force* (stating, warning, promising, etc.). If I *promise* that I'll be home for dinner and later *state* that I'll be home for dinner, my actions might be instances of a single locutionary act: both actions might involve the content that I'll be home for dinner. However, my actions are instances of different illocutionary acts: one has the force of a promise, while the other has the force of a statement. (Austin, 1962b, pp. 98–101)
>
> *The perlocutionary act*: an act classifiable by its "… consequential effects upon the feelings, thoughts, or actions of the audience, or of the speaker, or of other persons …." If I warn that the ice is thin, and so perform one illocutionary act, I may thereby perform a variety of perlocutionary acts: I may *persuade* someone to avoid it, or *encourage* someone to take a risk, and so forth. (Austin, 1962b, p. 101)

Crucially, these are distinctions amongst types of things that one might do, rather than amongst individual actions. It is possible for a single action to instantiate all three types of act: a speaker's saying something might be their uttering some words with particular meanings, their inviting someone to leave, and their inducing a guest to feel unwelcome. Moreover, as in other cases of human action, the various things a speaker does will often be ordered as means to ends: the speaker might have uttered those words *in order to* produce

an invitation; and they might have produced the invitation *in order to* make their guest feel unwelcome. Thus, we can see how the meanings of the words that the speaker used, which figure most directly in the locutionary act that they performed, figure less directly in the illocutionary act or acts that they perform, and less directly still in the further, perlocutionary consequences of the performance of that illocutionary act.

Consider, for example, saying to a guest, "You should leave now." Performing that locutionary act might be a means to the performance of any of a variety of illocutionary acts. For instance, one might give an order or make a statement. And one might use the same words without either ordering or stating that the guest should leave, for example if one uttered those words as part of a larger construction: "If your train arrives at 10 p.m., you should leave now." Attempting to account for that variety just by appeal to meaning would lead to an implausibly complicated account of meaning. Similarly, performing one of those illocutionary acts – say, ordering the guest to leave – might be a means to the performance of any of a variety of perlocutionary acts: one might encourage the guest to leave, or to stay; one might thereby reveal one's inhospitality towards the guest, or one's hospitality to other guests; one might cause the guest's enmity, or induce in them a grudging respect; and so forth. Again, any attempt to account for that variety by appeal just to meaning would be bound to lead to implausible complications. Austin's tripartite distinction made clear that there is no reason to try to explain all the things that can be done by the use of some words by appeal only to the meanings of those words. Unlike locutionary acts, illocutionary and perlocutionary acts are to be explained not only by appeal to meanings, but also by appeal to a combination of further factors, including speakers' illocutionary and perlocutionary ends, and other features of the broader circumstances in which the act of speaking takes place. However, Austin's discussion left open the precise nature of the distinctions between locutionary, illocutionary, and perlocutionary acts, and provided inadequate guidance to the application of those distinctions. (See Bird, 1981; Hornsby, 1988; 1994; 2006.)

3 Grice on Illocutionary Acts

Paul Grice's work on what he called "non-natural meaning" provided the basis for one way of trying further to develop Austin's three-way distinction (Grice, 1989, pp. 213–223). As we'll see, it also furnished a motivation for drawing further distinctions within the field of illocutionary acts. Grice sought to contrast non-natural meaning with natural meaning. An example of natural meaning would be the connection between black clouds and impending rain that is specified when one claims that those black clouds mean rain. To a good first approximation, the connection is *factive* – if rain is not forthcoming, then it wasn't the case that the clouds meant rain. And except in special cases, the connection is independent of anyone's beliefs or intentions: the fact that the clouds mean rain has nothing to do with what anyone believes or intends about the clouds or about the rain. (Special cases might include cases in which someone's behavior means that they intend or believe something.) Examples of non-natural meaning would be the fact that those three rings on the bell mean the bus is full, or that, in saying, "The bus is full," the conductor meant that the bus is full. By contrast with natural meaning, non-natural meaning is non-factive and does appear to depend on speakers' intentions.

Grice proposed an account of non-natural meaning that was given by appeal to speakers' intentions to have certain cognitive effects on an audience on the basis of the audience's

recognition of some of the speakers' intentions. In one of Grice's formulations, appeal is made to a reflexive intention – an intention the content of which makes reference to itself:

> "*A* meant$_{NN}$ something by *x*" [that is, a speaker, *A*, non-naturally meant something by producing some behavior – say, an utterance – *x*] is (roughly) equivalent to "*A* intended the utterance of *x* to produce some effect in an audience by means of the recognition of this intention"; and we may add that to ask what *A* meant is to ask for a specification of the intended effect… (Grice, 1989, p. 220)

It is this type of formulation, given in terms of reflexive intentions, to which some theorists have appealed in trying to clarify the nature of illocutionary acts. On this account of illocutionary acts, what marks out illocutionary acts from other kinds of act is that an act is illocutionary just in case the intended audience's recognition of the intention with which the act is undertaken – the intention recognizably to perform one or another illocutionary act – suffices for its successful completion. (See Bach and Harnish, 1979; Hornsby, 1994; McDowell, 1980; Searle, 1969. For a useful critical summary of attempts to account for the nature of illocutionary acts, see Bird, 1981.) When illocutionary acts are understood in this way, they are distinguished clearly from perlocutionary acts. For example, one might act with the perlocutionary intention that one's action should induce an audience to leave, but one's audience might recognize one's intention without leaving and, so, without their recognition of one's intention sufficing for achievement of the perlocutionary end with which one acted. By contrast, if one acted with the illocutionary intention that one's audience recognize one's illocutionary intention – say, one's intention recognizably to order one's audience to leave – then it would suffice for success that one's audience did recognize that intention. Moreover, if we assume that locutionary acts, and the intentions with which they are undertaken, can be characterized without appeal to potential effects on an audience, the appeal to the presence or absence of reflexive intentions provides the basis for a clear distinction between locutionary and illocutionary acts.

Let's suppose that Grice's account of non-natural meaning can serve in this way to sharpen the boundaries of the class of illocutionary acts. The picture that emerges is one in which some of a speaker's actions instantiate at least three types of act: locutionary acts – the utterance of some meaningful words; illocutionary acts – the production of some behavior (for example, behavior instantiating a locutionary act) with the intention to make recognizable an intention to perform a certain type of illocutionary act; and perlocutionary acts – the production of some behavior (for example, an illocutionary act) with the intention of having effects over and above an audience's recognition of one's illocutionary intentions. Moreover, it is a picture on which the three types of act are typically related as means to ends: the speaker utters some words in order to perform an illocutionary act – in order, that is, to make recognizable their illocutionary intentions; and the speaker performs that illocutionary act in order to achieve further perlocutionary ends.

So stated, the account is deceptively simple. Room must be made for some additional complications that arise from the role of intentions in the account. For one thing, intentions figure in rational psychology, and are plausibly subject to rational constraint. In particular, one can rationally intend to Φ only in so far as one holds that it is possible for one to Φ. So, one can rationally intend to make recognizable one's illocutionary intention by performing a locutionary act in particular circumstances only in so far as one holds that it's possible that one's performance of the locutionary act in those circumstances will make recognizable

one's illocutionary intention. Furthermore, it's plausible that one can rationally intend to make recognizable one's illocutionary intentions only if it is *reasonable* for one to hold that it's possible that one's performance in those circumstances will make recognizable one's intention. Thus, if we build into Grice's account that meaning-determining intentions must be rational, the outcome will be one on which meaning-determining intentions are highly constrained by what it's reasonable to expect concerning the interaction of one's overt performance with the recognitional capacities of one's audience. In addition, we shouldn't expect that the intentions with which a speaker acts invariably will form a consistent set. Even amongst the fairly rational, cases are likely to arise in which a speaker's intentions can't all be satisfied. For instance, one might use the words, "He smokes," with the intentions, first, to speak about a man and, second, to speak about a salient individual who is not in fact a man. In such cases, judgment will be required in moving from facts about the speaker's intentions to facts about the illocutionary acts that they have performed.

Modulo those complications, the account seems to make space for a simple view about the relationship between locutionary and illocutionary acts, at least with respect to a range of central cases in which a speaker intends to exploit the meanings of their words in order to perform an illocutionary act. According to the simple view, word meanings are combined into sentence meanings in such a way as to determine that each sentence expresses a unique proposition. It is that connection between sentence and proposition that speakers exploit in order to reveal their illocutionary intention. In central cases, speakers intend to use a sentence as expressing whatever proposition is determined by its meaning in order to make recognizable their illocutionary intention to state, order, question, and so forth. In those cases, where the proposition determined by the meaning of *S* is that (or whether) *p*, and Φ is the illocutionary act type that the speaker intends to perform (e.g., stating, ordering, asking, and so forth), the speaker utters *S* in order to Φ that (or whether) *p*. According to this simple view, sentence meaning determines the propositional content of the illocutionary act, and the remaining shift from locutionary to illocutionary act is a matter merely of the determination of illocutionary force. So, the simple view fixes a backward route from illocutionary act content to meaning, and thereby puts the theorist in a position to discern facts about sentence meaning fairly directly from facts about the illocutionary acts that the sentence may be used to perform. On such a view, claims about meaning, what is stated, and truth-conditions will tend to run in step. Thus, distinctions between semantics and pragmatics on which semantics is held responsible either for meaning, or for what is stated, or for truth-conditions, will also tend to run in step. However, although the simple view is attractively simple, Grice argued that the assumption about the connection between meanings and the contents of illocutionary acts on which the simple view depends is not tenable.

4 Grice on Basic and Derivative Illocutionary Acts

In addition to sharpening Austin's distinctions between locutionary, illocutionary, and perlocutionary acts, Grice recognized the importance of drawing further distinctions within the field of illocutionary acts. In doing so, Grice was responding to philosophers who, as he understood them, endorsed something like the simple view of the relation between meaning and illocutionary acts sketched in the previous paragraph. Because they endorsed versions of the simple view, they were willing to draw conclusions about the

meanings of sentences on the basis of observations about the propositional contents of illocutionary acts that those sentences can be used to perform. Adherence to the simple view gave rise to two main difficulties. The first difficulty was that accounts of meaning based on the simple view tended to be very complex, reflecting, as Grice saw it, the fact that the connection between meaning and illocutionary act is less direct than the simple view makes it out to be. The second, related difficulty arose because the simple view led to treating as ambiguous words and sentences that might otherwise have seemed to express unitary meanings (Grice, 1989, pp. 3–21).

The basic difficulty here is that the form of words constituting a sentence can be used in order to perform illocutionary acts with a wide variety of different propositional contents, depending on variation in speakers' illocutionary intentions. To take an example connecting the first two difficulties, Peter Strawson had noticed that sentences of the form "It is true that *p*" were typically used in the performance of illocutionary acts in which it was suggested that someone had stated, or might state, that *p*. The simple view thus conditioned him to assume that that suggestion was determined by the meanings of sentences of that form (Strawson, 1949). However, where the form of words constituting that sentence are embedded in certain larger structures – for example, "If it is true that *p*, then *q*," or, "Either it is true that *p* or it is true that *q*" – the apparent correlation of word form and illocutionary suggestion lapses (Geach, 1965). The form of words can be used in different circumstances to perform illocutionary acts with different propositional contents. Thus, if one sought to explain the variety by appeal only to sentence meanings, one's account of meanings would again be required to be implausibly complicated.

Grice's response was based on the observation that very often, in performing actions that seem to exemplify a single locutionary act, speakers thereby perform a plurality of illocutionary acts. Moreover, he observed that that plurality is typically organized so that some of the basic illocutionary things speakers do serve as means to other, derivative illocutionary things that they do. Thus, to modify one of Grice's own examples, a speaker might respond to a query about the philosophical competence of one of their students by uttering the words, "They have neat handwriting." In performing that locutionary act, the speaker would be performing the following basic illocutionary act: they would be stating that the student in question has neat handwriting. However, given the circumstances in which the speaker performed that act, they might also be performing one or more derivative illocutionary acts: they might, for example, be implying, or insinuating, that the student in question was not a very good philosopher. Just as the speaker would intend the first illocutionary act to be recognizable, so they would intend the second to be. Moreover, the speaker would be performing the first illocutionary act in order to perform the second: they would intend their audience to recognize what they had stated and, on that basis, to come to recognize their further illocutionary intention to imply, or insinuate, that the student is philosophically incompetent. Thus, the new distinction within the field of illocutionary acts mirrors Austin's broader distinction between illocutionary and other acts. Grice called the propositional contents of the derivative illocutionary acts *implicatures* (Grice, 1989, pp. 3–143, 224–247; Soames, 2003, pp. 197–219).

(In addition to cases in which a speaker performs a basic illocutionary act in order to perform derivative illocutionary acts, Grice allowed for the possibility that a speaker might perform other illocutionary acts on the basis of only "making as if to" perform a basic illocutionary act (Grice, 1989, p. 30). Given the structure of Grice's account, it would be natural to treat the act of making as if to perform an illocutionary act of some type as itself

an illocutionary act, albeit of a different type. However, an alternative would be to treat making as if to perform an illocutionary act as the performance not of an illocutionary act, but only of a locutionary act. In taking that line, we would allow that some illocutionary acts are derivative not from the performance of more basic illocutionary acts, but from the performance only of locutionary acts. See Bach, 1994; 2001.)

Grice offered two sorts of accounts of cases of implicature. The first account was of what he called *conventional implicature*. Here, the central idea is that it is a feature of the meanings of certain words or sentences – or otherwise a conventional feature of those words or sentences – that their use is at the service of the performance of a plurality of speech acts (at least typically, or by default). Thus, just as a speaker can exploit the meaning of a sentence in order to help make recognizable their basic illocutionary intentions, so a speaker can exploit the fact that the use of a sentence conventionally carries certain implicatures in order to make recognizable their performance of derivative illocutionary acts with those implicatures as contents. The second account was of what he called *conversational implicature*. Grice's account of conversational implicatures is based on the idea that the ends of many central cases of linguistic interaction are, and may be presupposed by interlocutors to be, cooperative. Thus, with respect to many conversations, participants are entitled to assume that other participants aim to adhere to the following *Cooperative Principle*:

> Make your conversational contribution such as is required, at the stage at which it occurs, by the accepted purpose or direction of the talk exchange in which you are engaged. (Grice, 1989, p. 26)

The Cooperative Principle in turn may, in general, be implemented by appeal to a number of more specific maxims:

> *Maxims of Quantity*: 1. Make your conversational contribution as informative as is required (for the current purposes of the exchange). 2. Do not make your contribution more informative than is required.
>
> *Maxims of Quality*: 1. Do not say what you believe to be false. 2. Do not say that for which you lack adequate evidence.
>
> *Maxim of Relevance*: Be relevant.
>
> *Maxims of Manner*: 1. Avoid obscurity. 2. Avoid ambiguity. 3. Be brief (avoid unnecessary prolixity). 4. Be orderly. (Grice, 1989, pp. 26–27)

The Cooperative Principle and its sub-maxims are used in order to help explain how speakers are able to make manifest their performance of derivative illocutionary acts on the basis of their recognizable performance of more basic illocutionary acts. (In the case of the Maxims of Manner, which make appeal to the specific ways in which speakers are to say what they do, the performance of locutionary acts also figures.) The explanation goes via the standing entitlement of speaker and audience to assume that the speaker is aiming to adhere to the Cooperative Principle and maxims. Grice assumes that the basic illocutionary act performed by the use of a sentence will be accounted for more or less in accord with the simple view, so that its propositional content will be determined more or less directly by the meaning of the sentence. However, very often the way in which a speaker is observing the Cooperative Principle and maxims will not be obvious given only the basic locutionary and illocutionary acts that they have performed. Instead, it will be possible to see the speaker as adhering

to the maxims only on the assumption that their basic locutionary and illocutionary acts were shaped by their having certain beliefs and, moreover, by their reasonably intending it to be recognizable, in part by appeal to the assumption that they are observing the maxims, that they have those beliefs.

To see how this might work in a particular case, consider the following gloss on the example given above, involving someone responding to a request for information about a student's philosophical competence by saying, "They have neat handwriting." The audience might reasonably be expected to recognize that they were intended to reason in the following way: the speaker must be being cooperative since, otherwise, they wouldn't have replied to the request. The speaker cannot be unable to say something more relevant, since the question concerns one of their students. The speaker must, therefore, be wishing to impart information that they are reluctant to write down. This supposition is tenable only if the speaker thinks that the student is no good at philosophy. This, then, is what the speaker is implicating. (Gloss modified from Grice, 1989, p. 33. It's worth noting that Grice presented his account of conversational implicature as preliminary and partial and, moreover, as covering only a subclass of non-conventional implicatures. See, e.g., Grice, 1989, p. 26, but compare p. 31. Grice says very little about the class of non-conventional, non-conversational implicatures. Grice's main focus is on implicatures carried by natural language analogues of the logical constants, on which see Edgington, 2006.)

Grice's distinction between basic and derivative illocutionary acts – that is, between what a speaker strictly and literally states and what they implicate by stating it – can help to illuminate three important types of possibility.

The first type of possibility is that the very same basic illocutionary act might serve as a means to the performance of a wide variety of derivative illocutionary acts. For example, in some circumstances, as we've just seen, one might state that a student has neat handwriting in order to communicate skepticism about their philosophical ability. However, in other circumstances – for example, circumstances in which the student is applying for a position as an amanuensis – one might state the same thing in order to communicate their suitability for the role. Thus, the fact that a form of words can be used to perform illocutionary acts with a variety of propositional contents does not alone demonstrate that the form of words is ambiguous, or carries complex meanings that determine different propositional contents in different circumstances.

The second type of possibility is that speakers might be unwilling to state something, and might even judge that stating it would be incorrect, or that what was stated would be false, not because stating it would be incorrect, or because what was stated would be false, but rather because stating it would give rise to implicatures that were false and, so, would be misleading. Suppose, for example, that the applicant for the position of amanuensis in tomorrow's examination had been injured and would not be able to write until the day after tomorrow. In that case, although it would remain true that the applicant has neat handwriting, one might nonetheless be unwilling to state that they have, since doing so would be apt to communicate that one thought them to be suitable for the position. Thus, the fact that in certain circumstances speakers are unwilling assertively to use some words, and even the fact that they would judge the assertive use of those words to be incorrect, or judge what was thereby communicated to be false, does not alone demonstrate that what would be stated in those circumstances would be false.

The third type of possibility is that speakers might be willing to state something, and might even judge that stating it would be correct, or that what was stated would be true, not

because stating it would be correct, or because what was stated would be true, but rather because stating it would give rise to implicatures that were true. For example, one might happily state that the injured applicant is not going to die with the intention of communicating that they will not die as a result of their recent injury. Thus, the fact that in certain circumstances speakers are willing assertively to use some words, and even the fact that they would judge the assertive use of those words to be correct or what was thereby communicated to be true, does not alone demonstrate that what would be stated in those circumstances would be true.

At the most general level, Grice offered an account on which there is no backward road from speakers' uncritical judgments about the correctness or incorrectness of the illocutionary acts performed by the use of some words to facts about the basic illocutionary acts that are so performed. And so, even on the assumption that there is a backward road from the propositional contents of basic illocutionary acts to facts about the meanings of the words used to perform those acts, the route from judgments about illocutionary acts *per se* to meanings is, at best, indirect. It's important to observe, however, that that consequence doesn't arise simply from Grice's account of the distinction between basic and derived illocutionary acts. Rather, it depends in addition on the view that speakers and audiences can sometimes be insensitive to the application of that distinction. Given that the range of illocutionary acts is supposed to be determined by speakers' intentions, and moreover by their intentions to make recognizable their intentions, the required form of insensitivity might reasonably be found puzzling. (See, e.g., Grice, 1989, p. 49; Recanati, 2004, pp. 5–22. Note that this issue appears most pressing when we attend to cases in which what is at issue is the distinction between a basic illocutionary act and derivative illocutionary acts performed on its basis. For in those cases, it is natural to assume that speakers and audiences will need to be cognizant of the intentions with which the various acts are performed. However, if we also allow cases in which a derivative illocutionary act is performed on the basis not of a more basic illocutionary act, but of a locutionary act, we might be more willing to allow that speakers and their audiences can be appropriately insensitive. See Bach, 2001.)

5 The Orthodox View

Grice's distinction between basic and derivative illocutionary acts ruins the simple view, on which the propositional contents of illocutionary acts are determined by the meanings of the words that are used in order to perform those acts. However, it makes available a more nuanced successor, which Grice also sought to defend: the orthodox view. According to the orthodox view, the propositional contents of *basic* illocutionary acts are to a large extent determined by the meanings of the words used to perform them. Variation in the illocutionary acts performed by the use of some words from occasion to occasion is therefore mainly due not to variation in the basic illocutionary acts that are performed, but rather to variation in the derivative illocutionary acts that are performed. More carefully, the orthodox view holds the following: (i) the propositional contents of basic illocutionary acts are to a large extent determined by the contents of locutionary acts; (ii) the contents of locutionary acts are determined by the meanings of the words that are used to perform them in combination with meaning-specified features of the circumstances in which the locutionary acts are performed; and (iii) the contents of locutionary acts determine truth-conditions or satisfaction conditions (where the latter are conditions in which a predicate like "is green"

would be true of an individual). (On the natural assumption that illocutionary act contents determine truth-conditions, (iii) approximates to a corollary of (ii), for locutionary act contents must be truth-conditional if they are to determine the truth-conditional contents of other acts.) According to the orthodox view, there are two sorts of cases in which the contents of basic illocutionary acts are not determined by the meanings of the words used in their performance.

The first sort, which we will henceforth ignore, comprises cases in which speakers advertently or otherwise perform basic illocutionary acts without intentionally exploiting the meanings of the words that they use in order to make recognizable their illocutionary intentions. This might happen if a speaker were intentionally to use a sentence in a way that departed from its meaning, but in such a way that they were nonetheless able to make recognizable their basic illocutionary intentions. Cases of this sort might include slips of the tongue, malapropism, and deliberately creative uses of language. (Davidson, 1986, contains a useful discussion of such cases.)

The second sort comprises cases in which speakers make use of sentences involving *indexicals* – for example, "I," "here," or "now," "She," and "That cat." These are expressions that, despite carrying unitary meanings, vary in the contribution that they make to illocutionary content. For example, "here" is used in order to say something about wherever the speaker happens to be, which might well vary from occasion to occasion. Similarly, "That cat" is used in order to say something about a cat that is distinctively salient, or that is made distinctively salient by an accompanying gesture. In both sorts of case, the meaning of the expression figures in making recognizable the basic illocutionary act that the speaker performs. However, it serves to make recognizable that act only in conjunction with information about the circumstances of speaking – for example, where the speaking takes place, or what the speaker is pointing at. The meanings of such expressions serve not to determine a specific contribution to the contents of illocutionary acts performed by their use, but rather to provide more or less detailed guidance about how information about circumstances is to be used in discerning such a contribution.

We can usefully distinguish two types of indexical, the discretionary and the non-discretionary. Non-discretionary indexicals – for example, "I" or "now" – have meanings that provide very detailed guidance to the ways in which the contents of acts performed by their use are to be discerned. The meanings of such expressions determine a range of relevant circumstantial features and specify the way that those features figure in determining a specific contribution to content. For instance, the meaning of the indexical "I" might be taken to determine a function from a specific feature of the circumstance – that is, the identity of the speaker (or "agent of the context") – to a contribution to truth-conditional content: reference to the speaker. Although the meanings of such expressions do not alone determine a contribution to truth-conditional content, those meanings combine with specific circumstantial features that the meanings select in order to determine such a contribution. Thus, in so far as the speaker intends to perform an act that exploits the meanings of such expressions, no further role is played by their illocutionary intentions either in determining the contents of that act or in selecting specific features of the circumstances that are to be exploited in discerning their illocutionary intentions. Rather, the meanings of the expressions dictate which locutionary acts are performed by their use, and combine with specific features of the circumstances of use in order to determine the contents of those locutionary acts. With respect to the use of non-discretionary indexicals, the orthodox view holds that locutionary content determines illocutionary content.

Discretionary indexicals offer less detailed guidance about how circumstantial features are to be exploited in order to discern illocutionary content. For instance, the meaning of "That cat" provides some guidance to discerning a speaker's illocutionary intentions – indicating, for example, that they intend to say something about a certain salient cat – but leaves it up to speakers how they will exploit, or manipulate, the circumstances of speech in order to make recognizable which cat they intend to say something about. Thus, since meanings alone fail to combine with circumstances in order to determine a truth-conditional content, determination of truth-conditional content for discretionary indexicals can't take place at the level of locutionary content. Rather, since the determination of truth-conditional content depends on speakers' illocutionary intentions, it occurs with respect only to the illocutionary act. With respect to the use of discretionary indexicals, the orthodox view allows that locutionary content fails to determine illocutionary content. Furthermore, the orthodox view allows that in such cases, locutionary content fails to determine truth-conditions, although it will typically still determine satisfaction conditions. For although the locutionary use of "That cat is on the mat" will fail to determine to which cat the speaker intends to refer, it is open to hold that it will determine that the sentence is true of something if and only if it is a cat and is on the mat. (See, e.g., Bach, 1992; Perry, Chapter 38, THE SEMANTICS AND PRAGMATICS OF INDEXICALS.)

Returning to the general character of the orthodox view, we can now say the following. In cases in which a sentence is used intentionally in accord with the meanings of its constituent words and structure, those meanings figure in two types of way in making recognizable the propositional contents of basic illocutionary acts. First, the meanings of the sentence's indexical constituents serve as guides to the use of circumstantial information in discerning aspects of the speaker's illocutionary intentions. In the case of non-discretionary indexicals, this is a matter of determining the content of the locutionary act performed by their use. In the case of discretionary indexicals, it is a matter of determining the content of an illocutionary act. Second, the meanings of the sentence's remaining constituents, including non-discretionary indexical constituents, serve simply to determine the remaining contribution to locutionary, and so illocutionary, content. According to the orthodox view, then, there are only three ways in which a sentence could be used in accord with its meaning in order, on different occasions, to perform illocutionary acts with different propositional contents. First, the sentence might be used in order to perform derivative illocutionary acts with any of a variety of contents, as long as that variety were explicable by appeal to a combination of the performance of a basic illocutionary act together with the Cooperative Principle (or principles of broadly the same sort). Second, a sentence might be used in order to perform basic illocutionary acts with a variety of contents if the sentence were to involve indexicals. Third, a sentence might be used in order to perform illocutionary acts with a variety of contents if the sentence were ambiguous, so that it could be used in accord with different of its meanings on different occasions.

As noted in the introduction, attempts to sharpen the division between semantics and pragmatics have been guided by a number of considerations. The first and most important consideration is the idea that semantics should concern information about some of the stable, broadly conventional properties of words and sentences: the meanings of those words and sentences. Such information is of a sort that can be learned in advance and then brought to bear in seeking to understand particular uses of those words and sentences. The second consideration is that semantics should figure in explaining what speakers are able to state, or ask, or command, by the use of words and sentences – that is, it should have something to say about

the propositional contents of basic illocutionary acts. The third consideration, which may be viewed as a consequence of the assumption that the propositional contents of speech acts determine truth-conditions, is that semantics should have something to say about truth-conditions. The orthodox view allows for a division of labor between semantics and pragmatics that comes close to respecting all three considerations. For according to the orthodox view, the stable properties of words and sentences for the most part determine the propositional contents of locutionary acts that are performed by their use. And the contents of those locutionary acts for the most part determine the contents of basic illocutionary acts. In so far as the determination of illocutionary content is due only for the most part to the contents of locutionary acts, that is due to the operation of discretionary indexicals, and so leaves open that in cases in which locutionary act contents fail to determine truth-conditions, they nonetheless determine satisfaction conditions. For although the meaning of 'That is green' leaves it up to speakers' discretion what 'that' is used to refer to, it might be held that 'is green' is true of any such thing (or is satisfied by that thing) if and only if it is green. So, although the orthodox view treats the effects of discretionary indexicals as falling partly within the remit of pragmatics, rather than semantics, it accords to meaning, and so semantics, responsibility for all other effects on locutionary and illocutionary act contents, including the potential effects of non-discretionary indexicals.

Although the orthodox view is widely endorsed, in recent years it has come under increasing pressure from the defenders of views on which the connection between meaning and the propositional contents of basic illocutionary acts is taken to be less straightforward. As we noted, discretionary indexicals differ from non-discretionary indexicals in that they do not fully specify a function from specific features of circumstances of use to a contribution to propositional content, but instead provide only more or less detailed guidance to the discernment of speakers' illocutionary intentions. Opponents of the orthodox view seek to treat that sort of model as more generally applicable: in general, the meanings of words don't determine a contribution to the contents of basic illocutionary acts, but rather provide guidance to that contribution. (Importantly, their claim is that substantive expressions are in that specific way like discretionary indexicals, not that they simply are discretionary indexicals. For one important difference, 'is green' seems to provide more detailed guidance as to the kinds of things that can be stated by its use than do expressions like 'that'.) By contrast with the orthodox view, the opposing view holds that substantive word meaning rarely, if ever, provides sufficient guidance to facilitate recognition of speakers' basic illocutionary intentions. Speakers must therefore exploit features of the circumstance of speaking over and above the meanings of the words and sentences that they use in order to make recognizable their basic illocutionary intentions. On this view, the tasks of making one's basic illocutionary intentions recognizable, and of recognizing another's basic illocutionary intentions, will often exploit the sorts of information and principles that figure on the orthodox view only in mediating the transition from basic to derived illocutionary acts. Furthermore, just as discretionary indexicals fail to determine a contribution to truth-conditional content, so word meanings in general fail to determine such a contribution. Truth- and satisfaction conditions are determined not at the level of meaning or locutionary act, but only at the level of illocutionary act.

One main motivation for opposition to the orthodox view comes from the fact that our judgments about what sentences can be used to state in particular circumstances seem to vary in ways that don't obviously fit the orthodox view. That is, our pattern of judgments isn't easily accounted for by appeal either to ambiguity, or to the operation of ordinary indexicals or demonstratives, or to distinctions between the contents of basic and derived illocutionary acts. In the following two sections, we'll briefly consider an argument of this

sort against the orthodox view due to Charles Travis (Chapter 6, PRAGMATICS). Connectedly, we observed earlier that interesting applications of the distinction between basic and derivative illocutionary acts rely upon treating competent speakers as somewhat insensitive to the way the distinction applies. Opposition to the orthodox view has been bolstered by an unwillingness to treat the pattern of competent speakers' judgments as due to an insensitivity to the sorts of distinctions between basic and derivative illocutionary acts that would be required in order to preserve the orthodox view. (Related attacks on the orthodox view may be found in Austin, 1962a; Bach, 1994; 2001; Carston, 2002; Neale, 2005; Pietroski, 2003; 2005; Recanati, 2004; 2010; Sperber and Wilson, 1995; Travis, 2008.)

6 Occasion-Sensitivity

In the previous section, we saw that the orthodox view is committed to the following claims:

(OV1) Most substantive expressions, other than explicit discretionary indexicals, do not function in a similar way to discretionary indexicals.

(OV2) With respect to those substantive expressions, meaning combines with features of circumstances of speech to determine the content of speakers' locutionary acts in a way that doesn't depend on speakers' further illocutionary intentions.

(OV3) With respect to the use of such expressions, locutionary act content determines basic illocutionary act content.

(OV4) Basic illocutionary act content determines truth-conditions.

(OV5) With respect to the use of such expressions, locutionary act content determines truth-conditions.

(OV4), the claim that basic illocutionary act content determines truth-conditions, is common ground between Travis and proponents of the orthodox view. Travis aims to provide reasons to reject (OV3) and (OV5). He does so by attempting to show that the truth-conditions determined by basic illocutionary acts vary in a way that cannot be explained by appeal to the possession of truth-conditions by locutionary acts or by the role of explicit indexicals. If successful, Travis's argument would in the first place undermine (OV3), by showing that the connection between locutionary act content and basic illocutionary act content is in general – not only in cases involving explicit discretionary indexicals – less straightforward than the proponent of the orthodox view maintains. Contrary to (OV1), most substantive expressions would function in a similar way to discretionary indexicals: their meanings would provide more or less detailed guidance to discerning speakers' illocutionary intentions. In the second place, Travis's rejection of (OV3) would put pressure on (OV5). One source of pressure here is the apparent dependence of (OV5) on (OV4): if the only reason for holding that locutionary act contents determine truth-conditions were that those contents determine illocutionary act contents that determine truth-conditions, then that reason would lapse with rejection of (OV3). A further, connected source of pressure is that assessment as to truth seems typically to be directed at the contents of illocutionary acts. We typically seek to ascertain, for example, whether what someone states is true or false. If there were cases in which locutionary act contents determined illocutionary act contents, as per (OV3), then

truth assessments of illocutionary acts could in those cases be used in order to gain insight into the truth-conditions determined by their corresponding locutionary acts. However, in the absence of that connection between locutionary and illocutionary acts, it would be difficult to see how to gain purchase on the truth-conditions supposedly determined by locutionary act contents. Minimally, Travis's argument presents the defender of a truth-conditional conception of meaning or locutionary content with the challenge of providing grounds other than the combination of (OV3) and (OV4) for endorsing their conception.

Travis develops an argument against the orthodox view based around cases like the following:

> Pia's Japanese maple is full of russet leaves. Believing that green is the color of leaves, she paints them. [Case 1:] Returning, she reports, 'That's better. The leaves are green now.' She speaks truth. [Case 2:] A botanist friend then phones, seeking green leaves for the study of green-leaf chemistry. 'The leaves (on my tree) are green,' Pia says. 'You can have those.' But now Pia speaks falsehood. (Travis, Chapter 6, PRAGMATICS)

According to Travis, we can suppose that the same words, with the same meanings, are used in both cases. Moreover, we can assume that the operations of discretionary and explicit non-discretionary indexicals are confined to determining which leaves are being spoken about, and that the same leaves are being spoken about in both cases. Thus, we can assume that the same locutionary act, with the same locutionary content, is performed in case 1 and case 2. And since the same leaves, in the same condition, are being spoken about in both cases, if 'The leaves are green' were used in both cases to make the same statement and, so, in accord with (OV4) to determine the same truth-conditions, then Pia would either state a truth in both cases, or state a falsehood in both cases. Since it is plausible that Pia can state a truth (and no falsehood) in case 1 and that she can state a falsehood (and no truth) in case 2, even though the leaves are in the same condition in both cases, we have that 'The leaves are green' is not used in both cases to make the same statement. So, we have that the statement that Pia makes in case 1 is not the same as the statement that she makes in case 2. Finally, if we assume that the statements that Pia makes in both cases are the contents of basic illocutionary acts, we have grounds for rejecting (OV3). For we have that Pia performed locutionary acts with the same contents and basic illocutionary acts with different contents and, moreover, that the difference in illocutionary content was not due to the operation of explicit discretionary indexicals. And since *n*-tuples of cases of this sort can be constructed for most, if not all, substantive expressions, there are grounds for generalizing Travis's conclusion: most, if not all, substantive expressions function in a similar way to discretionary indexicals.

Travis's argument depends upon three main assumptions. The first assumption is that the variation in truth-conditions exhibited across cases 1 and 2 affects basic illocutionary acts performed in those cases. For if the variance affected only derivative illocutionary acts, it would be consistent with maintaining (OV3). The second assumption is that the variation is not due to ambiguity. For if 'The leaves are green' was used with relevantly different meanings across the two cases, the variation in truth-conditions might be traced to a difference in locutionary act content. The third assumption is that the variation is not due to the operation of non-discretionary indexicality. For if it were due to such indexicality, then the variation in truth-conditions might again be due to variation in locutionary act content. Travis's second and third assumptions have been subjected to interesting challenges in

recent years. However, no clear case has yet been presented in favor of the view that the variation in truth-conditions that Travis highlights can be accounted for by a combination of non-discretionary indexicality and ambiguity. (For approaches that appeal to indexicals, see Rothschild and Segal, 2009; Stanley, 2000; 2002; 2005; Stanley and Szabó, 2000; Szabó, 2001. For an account that appeals in addition to ambiguity, see Kennedy and McNally, 2010. For discussion see Clapp, 2012; Collins, 2007. The main weakness exhibited by extant proposals is that no attempt has been made to provide evidence for a plausible account of a function from meaning-specified features of circumstances of speech to truth-conditional contents. Thus, such accounts seem, at best, either to mitigate discretionary variation without eradicating it, or to resolve into versions of Travis's position. Versions of that complaint are developed in Clapp, 2012, and Rothschild and Segal, 2009.)

7 Basic and Derivative Illocutionary Acts

As we saw in discussing Grice's distinction between basic and derivative illocutionary acts, theorists have been willing to allow that competent speakers can be insensitive to the distinction between what speakers state and the contents of derivative illocutionary acts that speakers thereby perform. If defensible, such an allowance would make space for the following response to Travis's argument. Although there is variation across cases of the sort that Travis emphasizes, that variation affects only the contents of derivative illocutionary acts. In so far as we are inclined to judge that there is variation in the contents of what speakers state in the cases that Travis presents, that is a mistake fostered by our insensitivity to the distinction between what speakers state and the derivative illocutionary acts that they perform on the basis of so stating.

The central difficulty with this position arises because illocutionary acts of stating embody intentionally undertaken commitments. Let's suppose that the locutionary act performed by use of 'The leaves are green' determines the content of a basic illocutionary act. That act is therefore performed in both case 1 and case 2. Since the content of that act determines truth-conditions, it will represent a harmless simplification to suppose that those truth-conditions are such as to make the illocutionary act false in both cases. To a first approximation, the illocutionary act has a content that would be true if and only if the leaves were naturally green. Thus, let's suppose that in case 2 Pia uses 'The leaves are green' in order to perform a basic illocutionary act with that content. As Travis maintains, and as Pia could easily be brought to accept, she thereby states a falsehood. However, contrary to Travis's description, Pia performs the same basic illocutionary act in case 1, thereby committing herself to something false in that case too, her protestations to the contrary notwithstanding. According to the position currently being considered, although Pia commits to a falsehood in case 1, she thereby also performs a derivative illocutionary act with a true content and thereby commits to something true. Furthermore, Pia's failure to recognize, or to accept, that she commits to a falsehood in case 1 is to be explained by her insensitivity to the distinction between basic and derivative illocutionary acts. That is, it is explained by her failure to recognize that in addition to committing herself to a truth by performance of the derivative illocutionary act, she committed herself to falsehood by performing the basic illocutionary act. The difficulty, then, is that it is hard to accept that in case 1 Pia openly and intentionally commits herself to a falsehood, even though that is something that she failed to recognize and would even be prepared to deny. That consequence is hard to accept

because it conflicts with the natural presumption that agents know the intentions with which they act. Furthermore, not only would Pia fail to recognize that she had openly and intentionally committed herself to a falsehood in case 1, but her audience would also fail to recognize it. And that consequence is in tension with the requirement that Pia should act with the reasonable expectation that her illocutionary intentions will be recognizable. (See, e.g., Bach, 1994; 2001; Soames, 2005.)

It's important to emphasize that the claim that Pia does not perform the same basic illocutionary act in cases 1 and 2, and so does not make the same statement, is compatible with allowing that she performs other types of act in both cases. As we saw, Travis allows that Pia performs the same locutionary act in the two cases. Thus, on a broadly locutionary understanding of what speakers say, as opposed to the illocutionary understanding that we've characterized in terms of what speakers state, Travis can allow that Pia says the same thing in both cases. (See, e.g., Bach, 2001; Travis explicitly allows that the same thing might be said in pairs of cases like those involving Pia in his 2008, p. 156.) All that Travis is committed to denying, as a consequence of his denial of (OV5), is that what speakers say – on the operative locutionary understanding of what they say – determines truth or satisfaction conditions. For that reason, arguments designed to show that Pia says the same thing in cases 1 and 2 are impotent unless supplemented with reason to think that what she says in both cases determines a single set of truth-conditions. (Compare Cappelen and Lepore, 2005; Cappelen and Hawthorne, 2009.)

In summary, then, the defender of the orthodox view has two options. First, they might try to show that Pia performs the same basic illocutionary act in cases 1 and 2. That would be a way of seeking to defend (OV3) and (OV5). In doing so, they would need to provide evidence not only that Pia says the same thing in the two cases, but that she makes the same statement, and thereby takes on the same commitments. They would thereby incur the burden of explaining Pia's insensitivity to the commitments that she thereby takes on. Second, they might try to argue that there are locutionary acts that Pia performs in both cases and that those acts have contents that determine truth-conditions. That would be a way of conceding (OV3) while seeking to defend (OV5). Since such acts are not illocutionary acts, and so are not determined by Pia's reflexive intentions, it is liable to be easier to explain why we are insensitive to their occurrence. However, for the same reason, it will be harder to defend the claim that such acts have contents that determine truth-conditions, since it will no longer be possible to use the connection between illocutionary acts and truth-conditions (as per (OV4)) in order to do so.

8 Conclusion

We began with the idea that semantics concerns the stable meanings of words and expressions while pragmatics concerns language use, or things done with words. We saw that that rough distinction is associated with other concerns, including a concern to understand the features of language and its use that are responsible for what speakers state, and for the determination of truth-conditions. According to the orthodox view, the initial distinction between stable meanings and use is connected with what is stated and with truth-conditions. For according to the orthodox view, word meanings combine with circumstances to determine the contents of locutionary acts, and locutionary acts combine with illocutionary intentions with respect to explicit discretionary indexicals in order to determine the contents of basic

illocutionary acts, including acts of stating. And illocutionary acts, including acts of stating, have contents that determine truth-conditions. Thus, there is a more or less direct connection between meanings, the things that speakers state, and truth-conditions.

We saw that the orthodox view comes under pressure from reflection on certain forms of variation in the illocutionary acts that speakers perform. According to the opposing view, personified here by Travis, the connection between meaning and basic illocutionary act contents – in particular, the things speakers state – is less direct, and is mediated by some of the same sorts of factors that the orthodox view exploits in order to connect basic and derived illocutionary acts. We considered, and provided some grounds for rejecting, a defense of orthodoxy that sought to treat the variations that Travis highlights as occurring only with respect to derivative illocutionary acts. However, deciding the outcome of the dispute over the standing of the orthodox view will require further work. In particular, it will require further work on the nature of illocutionary acts, the nature of illocutionary intentions, and the extent to which speakers and their audiences can be expected to be cognizant of the illocutionary acts that speakers perform.

Pragmatics

CHARLES TRAVIS

Here are two non-equivalent characterizations of pragmatics. Pragmatics (first version) concerns the linguistic phenomena left untreated by phonology, syntax, and semantics. Pragmatics (second version) is the study of properties of words which depend on their having been spoken, or reacted to, in a certain way, or in certain conditions, or in the way, or conditions, they were (Kalish, 1967).

Here are two equally non-equivalent characterizations of semantics. Semantics (first version) is, by definition, concerned with certain relations between words and the world, and centrally with those on which the truth or falsity of words depends: thus David Lewis's slogan, "Semantics with no treatment of truth conditions is not semantics" (Lewis, 1972, p. 169). Semantics (second version) is defined by this idea: "A theory of meaning for a language should be able to tell us the meanings of the words and sentences which comprise that language" (Platts, 1980, p. 2). So what a semantic theory of English, say, must do is, for each English expression, provide a specification of what it means. Semantics in general would be an account of the nature of such particular theories, or of their subject-matter.

Combine these different ideas, and you get a substantial thesis: such things as English sentences *have* statable conditions for truth, and meanings can be given in or by stating these. That *might* be wrong. Perhaps, as J. L. Austin suggested, questions of truth arise at a different level entirely from that of expressions of a language. Perhaps conditions for truth depend, pervasively, on the circumstances in which, or the way in which, words were produced. If so, then on the second version of pragmatics and the first version of semantics, semantic questions are pragmatic ones; whereas semantics (second version), however it is to be done, would have little or nothing to do with truth-conditions. Call this the pragmatic view.

This chapter argues that the pragmatic view is the right one; that it is intrinsically part of what expressions of (say) English mean that any English (or whatever) sentence may, on one speaking of it or another, have any of indefinitely many different truth-conditions, and that any English (or whatever) expression may, meaning what it does, make any of many

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

different contributions to truth-conditions of wholes in which it figures as a part. I will first set out the reasons for thinking so, then discuss a few of the most significant consequences.

The issue also emerges in asking what words are for. On one view, bracketing ambiguity, indexicals, and demonstratives (see Chapter 38, THE SEMANTICS OF PRAGMATICS AND INDEXICALS), for each declarative English sentence there is a thought which is the one it expresses; its role in English is to express that one. On the pragmatic view this is just what is not so. Independent of ambiguity, indexicality, and so on, what meaning does is to make a sentence a means for expressing *thoughts* – not some *one* thought, but any of myriad different ones. Meaning does that in making a sentence a particular description of how things are, so a means for describing things as that way. Any description admits of many different applications. The same description, applied differently, yields different thoughts. A right application, where there is one, is fixed by circumstances of producing the description, not just by the description itself. If a sentence may thus equally well express any of many thoughts, conditions for the truth of one of these cannot be conditions for the truth of the *sentence*.

1 Semantic Properties

There are properties words have, and would have, no matter how we understood them. Being spoken loudly or at 3 p.m. are two. Then there are properties words have, or would have, on one understanding of them, but would lack on another – properties words have, if at all, only in virtue of their being rightly understood in the way they are. I want to consider two classes of such properties.

The first sort of property is one of relating in a given way to truth (or falsity). Properties of being true (false) if, given, of, or only if, thus and so, or thus, or the way things are, are all within this class. (They are all properties words might have on one understanding, and lack on another.) For future convenience, I exclude being true or false *simpliciter* from this class, though I include being true (false) given the way things are. I call these properties *truth-involving*, and any set of them a *truth-condition*.

The second sort are properties identified without mention of truth, and on which truth-involving properties depend. Such properties include such things as describing X as Y, calling X Y, saying X to be Y, and speaking of X. The words 'is red,' for example, speak of being red and, on a speaking, may have called something red. These properties identify *what* words say. I will call them *content-fixing,* and any set of them a *content*.

One might wonder whether content-fixing properties are not really truth-involving ones in disguise – whether, for example, to call something red is not just to say (of it) what is true of such-and-such things, and true of a thing under such-and-such conditions. In what follows, we will find out whether that is so.

The properties indicated so far might reasonably be called semantic, not worrying overly for the moment about boundaries between syntax and semantics. I will call them that, and any set of them a *semantics*. The latitude allowed here means that not every semantics in the present sense is one words might have. Some semantic properties may exclude others. Calling something a fish, for example, may exclude, *tout court*, saying what is true of my piano. Call a semantics some words might have *coherent*, keeping in mind that a semantics might thus be coherent on some occasions for speaking, while not on others.

We can raise questions about a semantics, or sort of semantics, without saying which items might have it – whether, for example, English sentences or something else might do so. One thing we may ask of a given semantics is whether it *requires* any further semantics – whether there is a semantics which any words with it must have. Or we may ask whether it is supplementable in a variety of – perhaps mutually exclusive – ways; whether words with it may, for all that, have any of various further semantics.

It is interesting to ask, in particular, whether the semantics an English sentence has in meaning what it does is compatible with any of many supplementations, specifically with any of a variety of truth-conditions. To answer that we need not first say what semantics meaning does confer. We need only find a number of speakings of the sentence on each of which it had whatever semantics its meaning does confer; on each of which, as much as any of the others, those words *did* mean what they do mean. In specific cases we may convince ourselves of that much without knowing just *which* properties meaning confers.

2 The Pragmatic View

Is what a sentence means compatible with semantic variety – specifically variety in truth-conditions – across its speakings? Consider this sentence:

(1) The leaves are green.

The words 'are green,' meaning what they do, are means for calling things green. Similarly, meaning what they do, 'The leaves,' when spoken as in (1), purport to speak of some leaves. What its (present) tense means makes (1), on a speaking, purport (roughly) to speak of things at the time of that speaking. Consider speakings of (1) in which the words did all this, and in all other respects (if any) meant what they *mean*. Does that much semantics require them to have just *one* full semantics on all such speakings? Or is that much compatible with semantic variety, and, specifically, with those words having, on different speakings, any of many truth-conditions?

A story. Pia's Japanese maple is full of russet leaves. Believing that green is the color of leaves, she paints them. Returning, she reports, 'That's better. The leaves are green now.' She speaks truth. A botanist friend then phones, seeking green leaves for a study of green-leaf chemistry. 'The leaves (on my tree) are green,' Pia says. 'You can have those.' But now Pia speaks falsehood.

If the story is right, then there are two distinguishable things to be said in speaking (1) with the stipulated semantics. One is true; one false; so each would be true under different conditions. That semantics is, then, compatible with semantic variety, and with variety in truth-involving properties. So what the words of (1) mean is compatible with various distinct conditions for its truth.

But is the story right? There are just two grounds for rejecting it. First, one might reject its data by claiming that both speakings of (1), above, share a truth-value, require the same for truth, and are true of the same. Second, one might accept the phenomena as presented, but claim that they *are* accounted for by what (1) means – either by some ambiguity in (1), or by some particular way in which what (1) means makes what it says depend systematically on the circumstances of its speaking.

Consider the first option. Either the stipulated semantics makes (1) true of painted leaves, or it makes (1) false of them, *punkt*. If one of these disjuncts is right, appearances to

the contrary may be explained in any of a variety of ways. The first task, though, is to choose. Which disjunct is right? One must choose in a principled way. What the words mean must make one or the other disjunct plainly, or at least demonstrably, true.

What we know about what words mean will not solve this problem of choice. Nothing we know about what '(is) green' means speaks to this question: If an object is painted green, should its color count as what it would be without the paint, or rather as what it has been colored by painting it? Nor is it plausible that some further development in natural science might resolve this issue. So, it seems, the first option must be rejected. Nor, as we shall see, are colors an unfair example. There are similar problems for any simple predicate, ones left unsolved by what the words in question mean.

We must, then, begin on the second option. Its simplest version is that (1) is ambiguous, or that the words 'are green' are: in one of their senses, they are true of leaves painted green, in another, false of leaves merely painted green. Does 'is green' have such senses in English? I do not think so. But there is a more important question. Suppose it does. Would that yield a different answer to our question about semantic variation?

It would change the answer if the only occasion for saying both true and false things of given leaves in speaking (1) were in case they were painted. But there are indefinitely many more occasions for saying either of two distinct things than that provides for. Suppose the leaves were not painted (or were painted red), but had a fluorescent green mould growing on them. Or suppose they are painted, but in pointillist style: from a decent distance they look green, but up close they look mottled. Is that a way of painting leaves green? It might sometimes, but only sometimes, so count. So there would be two distinct things to be said in the presumed 'paint counts' sense of 'is green.' And so on.

The above need not be the *only* ambiguity in the English 'is green.' But if words are ambiguous in English, there must be a way of saying just what these ambiguities are; so a fact as to how many ways ambiguous they are. The pair of speakings we considered differed in that each invoked a different understanding of what it would be for leaves to be green. There is no reason to think that there is any limit to possible understandings of *that*, each of which might be invoked by some words which spoke on that topic. There is not only an understanding on which painting might make it so, but also one on which painting might make it, so as long as this is not in too loose a pointillist style, or too shiny. And so on, *ad infinitum*. If 'green' has, say, 13 senses, there are, for each of them, various possible (and invokable) understandings of what it would be for leaves to be green in *that* sense. If so, then ambiguity is not a way of avoiding the present conclusion.

It is sometimes said: there is no *uniform* standard for things being green; it is one thing for an apple to be green, another for a tomato to be green, and so on. That idea, though, gets nowhere with the present problem. Throughout, the question has been what it is true to say of *leaves*.

Finally, it might be said that the phenomena show 'green' to be a vague term. Perhaps it is in some sense, though we have so far seen no more reason to say so than there is to say the same of any term. But it is hard to see how vagueness is to the point. In one sense, perhaps, words are vague if there is not enough in a correct understanding of them for deciding whether, given the way the things they speak of are, they ought to count as true or false. The *English* sentence (1) is certainly in that condition. But one *speaking* of it may clearly state what is true, while another clearly states what is false. That can only be so if the semantics of (1) on some speakings of it is substantially richer than that fixed for it by the meanings of its constituents, and richer in different ways for different such

speakings. So what (1) says on a speaking, of given leaves, and so on, is not determined merely by what it, or its parts, mean.

I take the English sentence (1) to illustrate, in the respects noted, what is generally so of a language's sentences – indeed, to illustrate how a sentence of a language *must* function. I have no space for more examples; nor for a satisfying account of why that should be.[1] The reader might anyway test the claim with some further examples of his or her own.

3 Domestications

The above, if correct, answers the initial question: what a sentence means, or what its parts do, is compatible with semantic variety; with variety in what such words say or said, and with variety in their truth-involving properties. One might think that compatible with the traditional view, in which semantics is both the study of what words mean and, centrally, of the conditions for their truth; that all said so far is consistent with the meanings of words determining the conditions for their truth; and even that the general point has long been recognized. One might still think, in other words, that the point may be domesticated within a framework in which what words mean still fixes, in an important sense, what they say wherever spoken. I will discuss two plans for such domestication.

The first plan turns on the idea of ellipsis: some words are to be understood as short for others. A particular 'He'll come,' for example, may be rightly construed as a shortened 'He'll come to the party.' Assuming ellipsis were pervasive, how might it help? If (1) may be used to say any of many things, it must, on different speakings, be elliptical for different things: on each it says what that for which it is then elliptical would say. For this explanation to domesticate the phenomena, the things for which (1) is elliptical must not themselves exhibit semantic variation of the sort that (1) did. For example, if a given instance of (1) is elliptical for 'The leaves are green beneath the paint,' there must not be more than one thing to be said in *those* words. If the phenomena are as I suggest, this assumption is wrong. I leave this suggestion at that.

The second suggestion revolves around this idea: what words mean *does* determine what they say.[2] But it does not do so *simpliciter*. Rather, it does so as a function of some set of factors, or parameters, in speakings of the words. The parameters allow for different things to be said in different such speakings. Such was always in the plan for linking sentences with truth-conditions.

The plan is illustrated by Frege's treatment of the present tense. Frege notes that a speaking of (1) in July might be true, while one in October was false.[3] He observes, correctly, that different things would have been said in each such speaking. One thing this shows is that the tensed verb refers to a specific time or interval, and different ones on different speakings; the words say the leaves to be green at that time.

Frege thought that more was shown. First, that for the present tense the time referred to is always the time of speaking. Second, that where present-tense words are spoken, there is a factor – the time they were spoken – and a function, fixed by what they mean, from values of it to the time they spoke of; in fact, the identity function. So third, that what (1) means determines a function from variables in its speakings to thoughts expressed on those speakings.

Frege's view might be generalized. What *some* words say, or contribute to what is said in using them, varies across speakings of them. Where this is so, the meaning of the words

does two things. First, it determines on just what facts about a speaking the semantic contribution of the words so spoken depends. Second, it determines just how their semantics on a speaking depends on these facts. Specifically, it determines a specifiable function from values of those factors to the semantics the words would have, if spoken where those values obtain.

The above is a hypothesis. *If* it is true, then while the words (1) may say different things on different speakings, what those words mean determines how they so vary. It determines that the words say thus and so where such-and-such factors take on such-and-such values, for any values those factors may take on (where the thus and so said is what would be true under such-and-such conditions). If that is so, it is reasonable to say that what words mean determines what they say, and when they, or that, would be true. It does so by determining effectively how other facts about their speaking matter to such questions.

But is the hypothesis true? First note that semantics is not history. Sentence (1) will have been spoken only a finite number of times before the heat death of the universe. Suppose that each such time something in particular was said. Then, of course, there is a function from parameters of *those* occasions to what was said in (1) on them. There are many such functions, from many such parameters. That is not semantics. What we wanted to know was: if you spoke (1) on such-and-such occasion (as may or may not actually be done), what *would* you say? The question was whether what (1) means provides an answer to that. The historical remark about actual occasions does nothing towards showing that it does.

The point was that the words 'is green,' while speaking of being green, may make any of many semantic contributions to wholes of which they are a part, different contributions yielding different results as to what would count as things being as they are said to be. Are there parameters in speakings of those words which determine just which semantic contribution they would make when? Is there a function such that for each assignment of values to those parameters, there is one particular contribution the words *would* inevitably make, spoken where those values hold? I will not demonstrate here that there are no such things. But there need not be: perhaps for any set of parameters, further possible factors would yield more than one distinguishable thing to be said for fixed values of those.

There are several respects in which the present phenomena are *unlike* central cases where the parameter approach seems promising. One difference is this. In central cases, such as 'I' and 'now,' pointing to given parameters seems to be a part of the terms' meaning what they do. It is part of the meaning of 'I,' and its use in English, that it is a device for a speaker to speak of himself. That suggests speakers as a relevant parameter. If there is no unique semantic contribution, 'I' makes for a fixed value of that parameter, the meaning of 'I' fixes no function from *that* to contributions made in speaking it. By contrast, it is not part of what 'green' means, so far as we can tell, that speakings of it speak of, or refer to, such-and-such parameters. If its contribution, on a speaking, to what is said is a function of some parameters – say, implausibly,[4] the speaker's intentions – saying so is not part of saying what 'green' means. The parameter approach does not *automatically* suggest itself here as it did with 'I.'

This difference between 'I' and 'green' shows up when it comes to saying what was said. Consider a speaking of the words 'I am in Paris.' Ignore any possibilities for various contributions by 'in Paris,' or by the present tense at a time. Then, knowing nothing more about the speaking, we know that, in it, it was said *that* the speaker, whoever s/he may be, was, at the time of speaking, whenever that was, in Paris. However in the dark we may be on those points, we *do* thus specify which fact (or non-fact) was stated. Not so for speakings of (1).

Suppose that Pia spoke those words, and that *we* say of that, 'Pia said that the leaves she spoke of were, at the time of speaking, green.' We will not have said *what* Pia stated unless *our* 'green' made some definite contribution to what *we* said about Pia. But, as we have seen, 'green' may make any of many contributions of the needed sort. If it made one such in *our* words and a different one in Pia's then what we said about her is *false*. We may, for example, have said her to say what would be false of green-painted leaves, while what she said would be true of that. The information contained in the meanings of the words she used is thus not enough for specifying, however uninformatively, *which* fact (or non-fact) she stated.

In speaking (1) literally, one does what then counts as calling leaves green. That may be one thing that sometimes counts as 'saying that the relevant leaves were green.' But *such* a use of 'say that,' if there is one, does not purport to specify which fact (or non-fact) was stated. It says nothing that allows us to associate what was said with a truth-condition for it. So it does not point to a function, fixed by meaning, from speakings to thoughts expressed in them.

A second contrast between present phenomena and such things as 'I' and 'now,' traditionally conceived, is suggested by this remark of Frege's:

> the content of a sentence often goes beyond the thought expressed by it. But the opposite often happens too; the mere wording, which can be made permanent by writing or the gramophone, does not suffice for the expression of the thought.… If a time indication is conveyed by the present tense, one must know when the sentence was uttered in order to grasp the thought correctly. Therefore the time of utterance is part of the expression of the thought.… The case is the same with words like 'here' and 'there.' In all such cases the mere wording, as it can be preserved in writing, is not the complete expression of the thought; the knowledge of certain conditions accompanying the utterance, which are used as means of expressing the thought, is needed for us to grasp the thought correctly. Pointing the finger, hand gestures, glances may belong here too. (Frege, 1977, pp. 10–11)

We begin with the idea that sentences are related to thoughts in this way: for each sentence there is a thought which is the thought it expresses.[5] With indexicality, we lose that idea. There is no particular thought which is the one the sentence 'I am here' expresses. Perhaps, though, we may regain that idea if we permit ourselves to generalize the ordinary notion of a sentence. Ordinarily, we think of a sentence as a string of words. Suppose, though, we drop that idea. Let us call something a symbol if it has two features. First, it is individuated by purely non-semantic features, as a word might be individuated by its shape.[6] Second, it has semantic properties, where we will take that to be so if it makes a definite, specifiable semantic contribution to the whole, or wholes, of which it is a part. We might regard a (generalized) sentence as a structured set of symbols in this sense. So, if Frege is right about its semantic contribution, a time of utterance may be a symbol, and hence a constituent of a sentence in this sense. An utterance 'The leaves are green' in July would then count as a different sentence from an utterance, 'The leaves are green' in October – an odd, but coherent, way to speak.

If the only deviations from the rule that, for each sentence, there is the thought it expresses are represented by the sort of case Frege has in mind, then we may now regain the initial idea in this form: for each *generalized* sentence, there is a thought which is the thought it expresses. But the phenomena exhibited by (1) cannot be domesticated in this way. There is no identifiable feature of a speaking of (1) which counts as a symbol in the present sense, and whose semantic contribution to the speaking is identifiable with precisely

the set of truth-involving properties (1) would have so spoken. If the phenomena (1) exhibits are pervasive, then even a generalized sentence, no matter what extra symbols it contained, might be used to say any of many things.

Wittgenstein held that any symbol is open to different interpretations; and that under different circumstances, different identifications of its content would be correct. That is the moral of his discussion of rules and what they instruct (Wittgenstein, 1953, §§84–87). His arguments apply as well to generalized symbols as to others. If he is right, then the demonstration omitted here, that the parameter approach *cannot* work, is anyway to be found.

4 Implicature

> Suppose that I were the doctor and a patient came to me, showed me his hand and said: 'This thing that looks like a hand isn't just a superb imitation – it really is a hand' and went on to talk about his injury – should I really take this as a piece of information, even though a superfluous one? (Wittgenstein, 1969, §461)

> I am sitting with a philosopher in the garden; he says again and again, 'I know that that's a tree,' pointing to a tree that is near us. Someone else arrives and hears this, and I tell him: 'This fellow isn't insane. We are only doing philosophy.' (Wittgenstein, 1969, §467)

Wittgenstein cites some bizarre things to say. We do not say such things, barring very special occasion to do so. But what does that mean? Suppose one says them anyway. Despite the oddity, might one have spoken truth?

The philosopher does acrobatics recklessly close to the tree. 'That's a tree over there,' someone warns. 'I know that's a tree,' he replies testily. 'Well, then, shouldn't you be more careful?' Here the philosopher speaks truth. So, one might reason, he *does* know these things. But one cannot cease to know things, or so it seems, *just* by moving from one conversation to another. So however bizarre saying so may be in other cases, for all that, he speaks truth there too. So one might reason.

But this is a bad argument. For it *may* be that words like 'I know I'm wearing shoes' vary their semantics from speaking to speaking. If some speakings of them speak truth, that does not mean that all will. We cannot generally reason: Pia spoke truth when she called the leaves green; so if I call them green, I will speak truth too. That was the moral of §2. The point would be, not that the philosopher ceases to know something by changing conversations, but rather, that on one occasion he counts as knowing such-and-such, on another not.

There is, though, a form of account on which many bizarre things we 'would not say,' would, for all that, be true. The idea is due to H. P. Grice. The starting point is the observation that saying is only one of numerous ways for words, or speakers of them, to represent things as so. There is also implying, suggesting, insinuating, presupposing, and so on. *That* insight did not originate with Grice. Grice, though, concerned himself with a particular class of such representations, which he called implicatures, using the verb 'implicate' for the sort of representing in question. Implicatures come in two sorts: conventional and conversational. Conventional implicatures are features of the meanings of the terms involved. They are illustrated by 'Pia dissuaded Tod from leaving,' and 'Sam struggled to reach the lectern.' The first represents Tod as at least having thought of leaving; the second represents Sam as facing some obstacle to reaching the lectern. But the first does not *say* that Tod had thought of leaving, nor the second that there was an obstacle. That does not yet mean that,

for example, the second might be *true* were there no obstacle. It leaves it obscure what could make it so. But it may facilitate arguing the point. In any event, just as to use 'It's green' to mean what it does *is* to call something green, so to use 'struggle' to mean what it does, in a case like the above, is to suggest or imply that there is an obstacle. Grice suggests that it is difficult to produce words with a conventional implicature without implicating that. Such implicatures are not, or hardly, what Grice calls 'cancellable.' That he takes to be a main identifying feature of them.

Some implicatures, Grice notes, arise only on certain speakings of words, so *are* cancellable. These Grice calls conversational implicatures, and he explains them thus (though in much greater detail than given here). In normal conversation, we represent ourselves as observing certain maxims, and may be supposed to do so. Grice calls these *conversational maxims*. Examples are: be cooperative, be brief, be informative, and be relevant. Sometimes a speaker *seems* to violate some of these maxims. But it may be that he would not have if such-and-such, and it may be unreasonable to take the speaker to be violating them. We may then reason thus. The speaker said that P (in saying 'W'). Saying P (or saying it in 'W') would violate the maxims unless Q. The speaker was not violating the maxims. So (according to him) Q.

A speaker may intend for us to avail ourselves of some inference of this sort, to a given conclusion that (according to him) Q. It may be part of the proper understanding of his words that he so intends. In that case, the speaker has, or his words have, conversationally implicated that Q. For example, Pia may say, 'Jones submitted a sequence of English sentences, divided into paragraphs, and titled "What is truth?"' If this is merely a way of saying that Jones submitted an essay, then it violates the maxim of brevity. Pia would not do *that*. So, by the suggested sort of inference, we may conclude that there is, according to Pia, something which distinguishes Jones's work from a proper essay – perhaps its incoherence. It may have been given to be understood that we were so to reason. In that case, the conclusion was conversationally implicated.

The notion of conversational implicature points to a particular sort of understanding some words, on some speakings, may bear. Nothing in the pragmatic view suggests that there should not be such understandings. Note, though, that, as Grice insists, for Q to be conversationally implicated in words 'W,' Q must follow from what 'W' said, or the fact that 'W' said it, or both. So we might ask what Grice thinks words say. He is quite clear about that:

> In the sense in which I am using the word *say*, I intend what someone has said to be closely related to the conventional meaning of the words (the sentence) he has uttered. Suppose someone to have uttered the sentence *He is in the grip of a vice*.… One would know that he had said, about some particular male person or animal x, that at the time of the utterance … either (1) x was unable to rid himself of a certain kind of bad character trait or (2) some part of x's person was caught in a certain kind of tool or instrument … But for a full identification of what the speaker had said, one would need to know (a) the identity of x, (b) the time of utterance, and (c) the meaning on the particular occasion of utterance, of the phrase *in the grip of a vice* [a decision between (1) and (2)]. (Grice, 1989, p. 25)

This is just the rejected conception of saying. On it, for example, bracketing lexico-syntactic ambiguity, we can always form a guaranteed-true report, in indirect speech, of what was said in any arbitrary speaking of given words: if the words were 'The leaves are green,' then that the relevant leaves were, at the relevant time, green. To think that is to miss the possibility

of occasion-sensitivity in the content of 'green.' So Grice's conception of saying cannot be assumed in any argument directed against an instance of the pragmatic view.

Grice aimed to resuscitate views fallen into disrepute, largely through what were, in effect, early applications of the pragmatic view. For example, the idea of conversational implicature was first developed specifically in aid of reviving some notion of a sense datum. With that in mind, let us return to the bizarre remarks with which this section began. Consider 'I know that that's a tree.' It would usually be bizarre to say that, for example, where the tree was in plain view and no doubt of any kind had arisen as to whether it was a tree. Grice invites us to entertain the possibility that the reason we would not say such a thing in such circumstances is that if we did, we would conversationally implicate something not so. He means that idea to encourage us to ask whether what would be said if one did so speak is anyway something true, or rather something false; and to expect one choice or the other to be *correct*.

In using 'know' bizarrely we *may* conversationally implicate something (though there is a problem if conversationally implicating that Q absolutely requires saying that P). But the pragmatic view offers another explanation of why, in some situations, we would not say 'I know that…' Suppose that 'know' may make any of many distinct semantic contributions to wholes of which it is a part, and varies its contribution from one speaking to another. Then, describing someone as he is at a time, we would, on some occasions, say something true in saying him to know that X is a tree, and, on other occasions, say something false in saying *that*. For there are various things to be said in so describing him. In that case, circumstances of a speaking of 'N knows …' may confer on it a supplement to the content provided by the meanings of the terms alone. For some such supplements, the result will be stating truth; for others it will be stating falsehood. But *some* circumstances may fail to confer a supplement of either of these sorts. Words produced in such circumstances would have a content still supplementable in either way. But a content still so supplementable can require neither truth nor falsity. Speak, in those circumstances of N knowing that it's a tree, and one will fail both at saying what is true and at saying what is false. Nothing either so or not-so will have been said to be so. Recognizing that, where it is so, may make one refrain from so speaking. In that case, the idea, encouraged by Grice, that if we said it anyway we would at least say something true or else something false, is simply a mistake. In that case, conversational implicature could not be a consequence of the fact of having said *that* such and such. There is no such fact.

That the content of words is consistently supplementable in more than one way is not in itself a block to those words stating truth. It is so only where different such supplements, or different ones within some range of reasonable ones, yield different results as to truth – where, that is, the content to be supplemented is compatible both with truth and with falsity. So it just *might* be that if you say irrelevantly, pointing at your brogues, 'Those things are shoes,' there is no compelling reason to deny that you have spoken truth (though the situation changes if you are wearing four-eyelet low moccasin boots, or even just moccasins). That is typically not how it is for philosophically sensitive terms like 'know.' That is one lesson the long history of skepticism teaches us. (If there must be an *occasion-insensitive* answer, just when *does* someone count as knowing there is a tree before him?)

This last point shows the problem in applying the notion of implicature where it is meant to carry philosophic baggage, notably where it is meant as a way of dismissing claims about what 'we would not say' as philosophically irrelevant. Where those claims point to occasion-sensitivity they are philosophically highly relevant. It is all very well to insist, for example,

that either Sam does or doesn't now know that he is wearing shoes, full stop; and that if you said, bizarrely, 'Sam knows he is,' you would either state truth or state falsity. Sooner or later, though, one must choose. Which is it? If, applying the pragmatic view, we carefully assemble a perspicuous view of the *different* things we at least take ourselves to say to be so, on different occasions for speaking of Sam, in saying him to know precisely that, then *either* there is a principled way of choosing between them (or choosing a further candidate) by appealing to what is recognizably so about what 'know' means, *or* they show that no one answer to the question is the right one occasion-independently. Prospects for the first alternative are dim.

5 Metaphysics

The English 'is green' speaks of a certain way for things to be: green. One might say that it speaks of a certain property: (being) green. If we do say that, we must also say this about that property: what sometimes counts as a thing's having it sometimes does not, so that there are, or may be, things which, on some occasions for judging, count as having the property, and on others do not. If for a property to have an extension (at a time) is for there to be a definite set of things (at that time) which are just those things (then) with that property, then this property does not have an extension, even at a time. Better put, it makes no sense to speak of 'its extension.'

Is all this just vagaries of the English 'is green'? Two related questions arise. First, might there be predicates which did not vary their contributions to what was said with them in the way that 'is green' does? If we said such a predicate to speak of a property, that property *would* have an extension, at least at a time. Such a predicate could not vary its contributions to wholes so that, in ascribing that property to an object (at a time) it would be possible to speak truth and also possible to speak falsehood. So there would be no call for saying of anything that it sometimes counted, and sometimes didn't, as having (at a given time) that property. Second, can we preserve the idea that (genuine) properties have extensions by supposing that predicates like 'is green' simply refer to different properties on different occasions (and that it is by their thus varying their referent that they make different contributions to different wholes)?

Why might one want properties to have extensions? First, one might think that we can gain this for properties by definition – by 'property' we just mean what has an extension – and that extensions are convenient means for counting properties (as one or two). Second, one might take such a view of properties as mere sane realism. We cannot change, say, the way a cow is by thinking about it. As a rule, the cow stays just as it is no matter how we think of it. And we may read, or misread, that sane thought thus: those ways for things to be which are, or count as, ways the cow is count as ways the cow is no matter how we think about the cow, or them. So for any genuine way for things to be, either the cow is that way (at a time), or it is not, *punkt*. The same goes for any other object. In which case, genuine ways for things to be have extensions (at times). But whatever there is in favor of this line of thought, I suggest that both our questions merit negative answers.

I begin with the first. I will state the main point, though there is here no space for detailed argument. Once we fix what 'is green' speaks of – green – we then note that there are different possible understandings of what it would be for an object (or some objects) to be *that* way (green). These are possible understandings in that they represent what one *might*

regard as a thing's being green. So, for each, some item may be said, in calling it green, to be green on *that* understanding of its being so. And for each, that may be the *right* understanding (on some occasion) of what being green would come to. 'Is green' provides a particular description for things, expresses a certain concept. What is said in using it depends not only on what that description is, but on how that description, or that concept, is, or would be, applied in fitting it to particular circumstances of its use.

Suppose, now, that we identify an understanding of being green – say, the understanding on which an item was said to be green in some particular speaking of 'is green.' We now introduce a predicate – say, 'is green*' – which, by stipulation, is to mean *is green on that understanding of being green*. This predicate speaks, as it were, of a finer-grained property than 'is green' (as such) does. May *this* predicate make different contributions to what is said in wholes of which it is part? It may if there are different possible understandings of what it would be to be green on that understanding; two different things to be said as to whether such-and-such *is* being green on that understanding of what it would be to be so. As far as we can tell, this always will be so. We understand, for example, that paint is to count as changing color, and not as hiding it. We now encounter a rather poor paint job: you *could* say that it covered the original color, but you could view the original color as still showing through enough that the object had not yet been made the color of the paint, even on the indicated understanding of its being that color. An understanding of being green, in so far as we can identify one, seems unable to foreclose in principle on the possibility of differing but, apart from particular surroundings, equally sane and sensible views of what *that* understanding entails.

A predicate about which the pragmatic view was wrong would be one which did not admit of different possible understandings of what it would be for some item to fit the description which that predicate provides (or for the description to fit some item). The right understanding of it would foresee every eventuality in or to which the description might be applied. There is reason to think that no such predicate is available to human beings, at least given the way we in fact cognitively conduct our affairs. Again, what is said in applying a given description depends on *how* it is applied, and how, in given circumstances, it ought to be.

Now for the second question. First, if the first point is correct, then no understanding *we* could have of being green, so none that might attach to a particular use of 'is green,' would be one on which 'is green' spoke of a property, if a property must have an extension. To paraphrase Wittgenstein, we refine our concepts, or understandings, for particular purposes – so that *in fact*, in the situations we face or expect, unclarity as to what to do or say does not arise. In doing that we neither reach, nor aim at, that absolute clarity on which we would speak of what had definite extensions. Where 'is green' has made different contributions to different wholes, we may identify different things for it to have spoken of each time – being green on this understanding, and being green on that one. So we may see the predicate as varying its reference across speakings of it. But we must not mistake these different things for properties with extensions. Second, if we cannot have a predicate for which the pragmatic view does not hold, then, equally, we have no means for specifying properties to which extensions may sensibly be ascribed. In any event, the phenomenon we have to deal with is not merely that predicates vary their contributions to wholes, but also that, whatever a predicate may be said to speak of – being such-and-such – what would sometimes count as an item's being *that* other times would not.

6 Perspective

Given words may have any of many semantics, compatibly with what they mean. Words in fact vary their semantics from one speaking of them to another. In that case, their semantics on a given speaking cannot be fixed simply by what they mean. The circumstances of that speaking, the way it was done, must contribute substantially to that fixing. As pointed out earlier, this does not mean that there is a function from certain parameters of speakings to semantics, taking as value for each argument the semantics words would have where those values held. It thus also does not mean that there might be a precise theory, generating, for each semantics words might have, necessary and sufficient conditions for their having that. Still, we may describe how circumstances do their work.

Here is one thought. The words 'is green' are a means which English provides for calling things green (describing them as green, etc.). If, in speaking English, you want to call an item green, those words will do. Speak them literally, seriously, and so forth, and you will then count as having done just that. The truth of what you say in calling an item green should turn precisely on whether the way that item is then counts as its being green. These two remarks jointly identify which truth-involving properties any such words must have: they are true of, and only of, those ways for things to be which counted, at their speaking, as the item they spoke of being green. Similarly for other English predicates.

Where you called an item green, the truth of your remark turns on whether it *then* counted as being green. On different occasions, different ways for an item to be would count as its being green. That variation means that, on different occasions, calling an item green will confer different truth-involving properties on your words. Consider two occasions which differ in this respect. On each, words which call an item green will have some set of truth-involving properties, which is, therefore, a possible set of such properties for words with that content to have. Each such set of truth-involving properties, and the property of calling that item green, cohere on at least some occasions for so describing things. But those truth-involving properties *cannot* be those of words with that content produced on the other. That would not correspond to what, on the other, counts as something's being green. So each of the above semantics, available as it is on some occasions, is unavailable on others. I can sometimes speak truth in calling painted leaves green; but I cannot do so in circumstances where their being so painted does not count as their being green.

Let us pursue this thought. Consider:

(2) Today is a sunny day.

Spoken on day D, (2) would, typically, speak of day D. It would also identify the day it speaks of in a particular way: it speaks of that day as the day of its speaking, and represents it as identified by that fact. Since some speaking of (2) has both the semantic properties just mentioned, the two jointly form a semantics which is at least sometimes coherent. Let D* be the day after D. Words produced on D* could not have the semantics just mentioned. They could not speak of D and say it to be sunny while, on their proper understanding, identifying the day they speak of as the day of their speaking. On day D, we may express, or think, a thought with both those features. On other days (in normal circumstances) we cannot. Let us say that words with a semantics which is only sometimes available, in the above sense, express a perspectival thought, and have a perspectival content.

Now the point of the discussion of 'is green' may be put this way. Perspectival thought is the normal and pervasive case. On one occasion, we call an item green (at a time), and thereby produce words with such-and-such truth-involving properties. On another occasion, we may, if we like, say the same item to be green (at that same time). But our doing that may require that our words have quite different truth-involving properties. Those of our first remark may not correspond to what would count, on the occasion of this further speaking, as that item's being green. If that is right, it is fair to suppose that perspectival thoughts are the typical sort of thoughts we think. One might say: we relate cognitively to the world in essentially perspectival ways.

Now consider two minor puzzles. First, I have said there is something true, and also something false, to be said of given leaves, and their condition at a given time, in saying them to be green. How can this be? Consider the true thing to be said. What could make it true, other than the fact that the leaves are green? But, if that is a fact, how could one speak falsehood in saying no more nor less than that about them? Second, if there *are* those two things to be said, then *say* them, or rather, state the true one and deny the false one. To do so, you would have to call the leaves green, and then deny that they are that, as in 'The leaves are green, and the leaves are not green.' But that is a contradiction, so cannot be true. So what the pragmatic view requires that it be true to say is something it could not be true to say. So the view is wrong.

The first puzzle's rhetorical question has a non-rhetorical answer. What could make given words 'The leaves are green' true, other than the presumed 'fact that the leaves are green,' is the fact that the leaves *counted* as green on the occasion of that speaking. Since what sometimes counts as green may sometimes not, there may still be something to make other words 'The leaves are green' false, namely, that on the occasion of *their* speaking, those leaves (at that time) did not count as green.

As for the second puzzle, we are challenged to say something literally unsayable – *not*: sayable-but-false, but rather not sayable at all. We ought to decline the challenge. On some occasion, words which call given leaves (at a time) green may (thereby) have truth-involving properties in virtue of which they are true. On some other occasion, words which deny those same leaves to be green may similarly be true. But given the way (described above) in which occasions work to forge a link between content-fixing properties and truth-involving ones, there is no occasion on which both these feats could be accomplished at once; so none on which 'The leaves are green and the leaves are not green' could have the semantics which a conjunction of those two truths would have to have. If the occasion is one on which the way those leaves are counts as their being green, then no words could have the semantics of the true denial; and *mutatis mutandis* if on the occasion the way the leaves are does not count as their being green. Each of the thoughts provided for above is a *perspectival* thought; and, in virtue of its perspectival character, unavailable to be expressed at all on any occasion on which the other is expressible.[7] The nature of semantic variation thus allows us to decline the challenge.

These are banal examples. In philosophy, neglect of perspectival thought often leads to more excitement. A philosopher may sense, for example, that our concepts apply as they do against a background of our natural reactions; if we naturally viewed things *quite* differently, we might apply the concepts we now have so as to speak truth in saying what it would not now be true to say. Asked to express some such truths, the philosopher is reduced to nonsense. Naturally enough. He was describing other perspectives. Some things said truly from them are not so much as expressible at all from his own.

7 Thoughts

Frege writes,

> Without offering this as a definition, I mean by 'a thought' something for which the question of truth can arise at all. (Frege, 1977, p. 4)

Thoughts, for Frege, are not words. For him words are true only in a derivative sense: just in case they express a thought which is. For words are always open to, and in need of, interpretation. They are true, if at all, only on a given understanding of them (even if it is their proper understanding). Words 'Mary had a little lamb' may be a remark on husbandry, or one on gastronomy and, perhaps, true if understood the first way, false if understood in the second. Truth and falsity seem to correspond to understandings words may have, rather than to the words themselves (which Frege conceives as a quite different matter). It is the understandings, as opposed to the words, which settle questions of truth and falsity. So, on his view, it is for understandings, and not for words, that questions of truth and falsity arise. Words, apart from an understanding, could not be true or false at all.

If words admit of interpretations, then conceivably they may bear different understandings on different occasions for understanding them. Such shifts in interpretation could bring with them shifts in truth-value. So if words were the primary objects for which questions of truth arose, it would be conceivable, for any sort of semantic object, that one and the same item should count as true on one occasion for assessing it, false on another.

Thoughts, for which questions of truth are, strictly speaking, to arise, are meant to be free in principle of both of the above features. They are to be absolutely immune to interpretation; and they are to be true or false absolutely, independent of the ways, if any, in which they enter into our thinking. On Frege's view, only such semantic objects could be material for logic.

We may extend the notion of semantic property so that thoughts have a semantics too. The semantic features of a thought will be just those features by which one thought may be distinguished from another. Among these will be such things as being about eating ovine, and such things as being true if Mary ate a bit of ovine, hence, on the above plan, both truth-involving and content-fixing properties. Its truth-involving properties are meant to be just those its content requires. Moreover, it is meant to have all this semantics intrinsically: any thought, no matter how encountered, is that thought iff it has that semantics. This means that the content of a thought – unlike the content of words – must determine its truth-involving properties *inexorably* (to coin a term): there are no two sets of truth-involving properties such that an item with that content might have the one but not the other, and also vice versa; there is *one* set of truth-involving properties which is *the* set any item with that content *must* have. For if not, then a thought's having that content might, on some occasions, make it count as having one set of truth-involving properties, and on others make it count as having another, counter to the tenet that every thought has its truth-involving properties intrinsically.

Why must thoughts have inexorable content? Suppose C is a non-inexorable content. Then there might be an item with C and truth-involving properties T, and an item with C and distinct truth-involving properties T*. But truth-involving properties are meant to be those which content requires. So these must be two items differing in further content-fixing features. This means that an item with C is, so far, open to interpretation: it might, for all

that, bear any of several distinct understandings. That is to say: it might, for all that, be, or (if words) express, or represent, any of several distinct thoughts. So C is not the (whole) content of a thought.

Thoughts are identified precisely by their semantics, whereas words are identified by shape, syntax, or spelling, or by the event of their production. The identity of words leaves their content open. So the content of given words must depend on further factors: on the character of their surroundings. This leaves it open that their surroundings might, on some occasions of considering them, count as conferring one semantics on the words, while on other such occasions those surroundings might count as conferring another. In that way, the semantics of words – how they are rightly understood – may be an occasion-sensitive affair. By contrast, the semantics of a given thought is meant to depend on *nothing*. So there are no such possibilities for variation across occasions in the semantics a given thought *counts* as having.

Thoughts, as thus conceived, are not open to interpretation. They are what Wittgenstein called 'shadows': semantic items interpolated between words and the states of affairs that make words true or false, and somehow more closely tied to those states of affairs than mere words could be. About shadows, Wittgenstein said:

> Even if there were such a shadow it would not bring us any nearer the fact, since it would be susceptible of different interpretations just as the expression is.[8]

How could this be true of thoughts? Could thoughts admit of interpretation? If so, how?

There are too many strands in our inherited notion of a thought to unravel them here. But here is a sketch of a framework for relevant issues. To begin, one *might* think to buy the semantic absoluteness of a thought – its immunity to interpretation – by stipulation. Wherever I would say something to be so in saying 'S,' and it is determinate what, I may, it seems, refer to a thought in saying 'the thought that S.' I may also say, correctly, it seems: 'The thought that S is true iff S.' In saying that, I ascribe a set of truth-involving properties to the thought I refer to; in fact, whatever such properties my words 'S' then had. For I say the thought to be true exactly where what is so according to my words 'S' is so. So, it seems, we might stipulate that the thought I thus refer to is precisely the one with those truth-involving properties.

This is not quite enough. A thought cannot *just* have truth-involving properties. It must have a content. What content should that be? Here we come up against another strand in the conception of a thought. A thought is meant to be something that can be expressed in various words, or speakings, on various occasions. If you now express a thought, I can later express that very thought virtually whenever I like. On any plausible version of that view, words W and W* may express the same thought while differing in content. Frege gives this example:

> If someone wants to say today what he expressed yesterday using the word 'today,' he will replace this word with 'yesterday.' Although the thought is the same, its verbal expression must be different in order that the change of sense which would otherwise be effected by the differing times of utterance may be cancelled out. (Frege, 1977, p. 10)

The word 'today' brings with it a different contribution to content than the word 'yesterday.' Frege's two sentences are not alike in content-fixing properties. Yet, for good reason, Frege

takes it that the one sentence, produced under certain circumstances, would express the same thought as the other sentence produced under certain others. If so, then the content-fixing properties of that thought are liable to vary across occasions.

The question is: just *how* may content vary while words express the same thought? One idea would be that W and W* express the same thought only if they apply the same concepts to the same objects. But this will not do. It does not even allow for Frege's example. It collapses completely if we return to the notion of perspective. On some occasions, in calling given leaves green one would state truth; on others, in calling those leaves green one would state falsehood (and not because the leaves changed). Apply a given concept to the leaves in different surroundings and you will produce words with very different truth-involving properties. The semantics of some such words, produced in given surroundings, is unavailable in other surroundings for any words. Words with the *content* of those words, in the other surroundings, may have truth-involving properties so different that, at least for some purposes, we cannot take them to have expressed the same thought. The false remark about the leaves, for example, was not the same thought as the true remark. So if, in the changed surroundings, one wants to express the same thought again, one must *not* speak of the same concepts and objects. What it would take to express the same thought again is nothing more nor less than an adequate paraphrase. If the original words were 'The leaves are green,' then, depending on surroundings, an adequate paraphrase might be 'The leaves are painted green.'

There is no space here for an account of what makes paraphrases adequate. But here are two remarks. First, adequate paraphrases may need to share crucial or relevant truth-involving properties; but they are unlikely to share *all* truth-involving properties. In remote enough circumstances, leaves may be green in the sense in which they were said to be in a given 'The leaves are green,' but not painted green (perhaps dyed); though, for current purposes, 'The leaves are painted green' was an adequate paraphrase. Second, suppose on an occasion I express a thought in saying 'The leaves are green.' Then whether, on another occasion, words W are an adequate paraphrase of what I said may well depend on the occasion for the paraphrase, and perhaps, too, on the occasion for considering that occasion.

Thoughts viewed from this position lose their claims to have some *one* semantics intrinsically, and to be immune to interpretation. If, with perspective in mind, we ask what would count as producing some given thought again, and if we consider all the occasions for posing that question, we see how *that* thought may count on some occasions as having semantics which it would not count as having on others. For it may on some occasions admit of paraphrases it does not admit of on others. Nor need it ever have an inexorable content. To see how thoughts admit of interpretation, one need only know how to look for occasions for interpreting them.

8 Concluding Remarks

There is much left to discuss, but no space left to discuss it. It is thus time to commend the subject to the reader. The pragmatic view gives a substantially different form to virtually every philosophic problem, not just in philosophy of language, but wherever puzzles arise. The new form may make some of these problems more tractable. For a start we will need new conceptions of logical form, and of such related notions as intensionality. These may yield new things to say on such questions as whether 'if–then' is transitive. We may then

take a fresh look at what we say of people in ascribing propositional attitudes to them, and at understanding itself. Such a look, I predict, would make philosophy of psychology take a fresh course. It is also worth a look, from the pragmatic view, at problems of knowledge, of explanation, of freedom and responsibility, and so on. Some of this work is begun. There is much left to explore.

Notes

1 For some more discussion see my (1989, especially ch. 1).
2 Throughout I leave lexico-syntactic ambiguity aside.
3 I modify Frege's example slightly. His discussion is in Frege (1977, p. 27).
4 See my (1991) for further discussion.
5 Once again, ignore lexico-syntactic ambiguity.
6 Strictly speaking, this is false of words (consider, e.g., homonyms). But ignore that for now.
7 More precisely, any occasion on which a thought with the semantics of the first is expressible is *ipso facto* one on which a thought with the semantics of the second is not. I do not mean to prejudge questions of thought-identity.
8 Reported by Moore (1954/1993).

Postscript

CHARLES TRAVIS

In Retrospect

Eighteen years ago I set out, above, a view on the relation of language to what is said in using it. I still think the view right. What *has* changed in the interim is the case I would make for it. Eighteen years ago this case consisted, in essence, in presenting the view and then disarming various anticipated objections to it. In the interim my ambitions have grown. Having stated the view, I would now aim to identify features of thought and its expression which would dictate occasion-sensitivity, both of words and of what they speak of. Not whether occasion-sensitivity is coherent, or *possible*, but rather why our form of thought requires it.

There are several lines one might pursue in making such a case. In present confines I merely outline one. It starts from an idea about what words are for. It continues with another about how deeply thought is world-involving. To arrive at the first we can start from Frege's idea of a *thought* (*Gedanke*). In a thought things are represented as some way there is for them to be. The thought itself may be said so to represent things. The thought is an abstraction from historical instances of representing (something) as (something): instances of thought-expression. It does not represent in the same aspect of the verb as that in which *we* represent in saying things. It is more an aspect in which for the *thought* to represent as it does is for that to be how *one* would represent in its expression. The thought abstracts from activities, or stances, in order to serve a particular purpose. Thoughts are to be that which laws of logic govern. Logic (for Frege) answers the question how one must think to reach the goal truth – but only in so far as the answer to that question is given by what being true is as such (1897, p. 139). The laws of truth unfold the concept *being true* (1918, p. 59). A thought identifies a particular way for *how* things are represented being to make truth depend on *what* is so represented. Thus (e.g.) a thought cannot be an object of sensory awareness, nor have any identifying feature which is (cf. Frege, 1918, p. 61). How

representing looks or sounds has nothing to do with when the way things are thus represented as being is a way things are. There is no such thing as two thoughts – a true and a false one, say – distinguished from each other in that one is written in Gothic script, the other not.

Such already tells us something Frege often stressed: a thought is quite un-language-like. For example, it is absolutely insusceptible to the kind of structure – syntactic – by which a *sentence* of some language is identified as the one it is. A thought and a sentence cannot share a structure. First, a sentence is assigned a structure in its generation by the syntax of its language. To be that sentence is to be *so* structured, full stop. Whereas for thoughts, following Frege, the whole thought comes first. It is, of course, decomposable into elements. But then in many different ways, and – unlike a sentence – into any of many diverse sets of elements. No one decomposition, as Frege tells us, can claim objective priority. (*Vide* Frege 1882, p. 118; 1892, pp. 199–200; 1919, p. 273.) Second, a thought is structured (or structurable) in terms of relations defined in terms of being true, whereas a sentence is structured in terms of relations defined in terms of being a sentence in its language. A structure of a thought on a decomposition is not a syntactic structure. (*Vide*, e.g., Frege 1897, p. 154.)

A thought, as noted, is invisible. Why should a sentence need to have a visible, or audible, form? Here is a clue. Pigs, or sheep, have a particular visible form, here a look. There is that distinctive porcine look; similarly that ovine look. A pig is (often) thus recognizable by sight. You can tell a pig by its porcine look. Perhaps, in some similar way, a sentence's look – that 'Pigs fly' look, so to speak, helps to make something recognizable. What? A sentence is not just all looks. It is (as a rule) also meaningful. What it means, or speaks of, matters in a specific identifiable way to what would be said in speaking it (as meaning what it does). So if you have recognized a sentence, in some production of it, by its looks and you know what it means (I here bracket ambiguity), and if that production was, recognizably, in an act of saying something, you have thus taken a significant step towards recognizing what was thereby said.

Saying something is a particular case of representing-as. It is (an act of) *authored* representing. It is an act *one* might be aware of. For things, in it, to be represented as a certain way is for such to be recognizable to *one*. A sentence is well designed to help in such an enterprise. Its perceivable form makes it identifiably instanced, occurring, independent of how, if at all, things are thus represented as being. In meaning what it does, it makes a specific contribution to identifying how things were said to be (or at least spoken of as being) in so employing it. Allorepresenting would not be impossible without this. But, arguably, without it we could hardly achieve the complexity and subtlety of the representing-as we in fact produce.

That language has the task of achieving recognizability, and that each meaningful expression of a language serves this in its own proprietary way, are not anywhere in serious dispute. The core idea I defended 18 years ago is what I would now put thus: serving the end of recognizability is the *sole* aim which linguistic meaning is tasked with serving; for an expression to mean what it does just is for it to contribute as it does to making the authored representing-as done in it recognizable as representing as it does. A language is *not* charged with itself containing truths and falsehoods – sentences which, just in meaning what they do, say what is either true or false (of things as they are) – nor, equally, with containing truths or falsehoods *of* n-tuples of given sorts – e.g., triples of an object, time, and place. I call this view the 'authoring tools view,' ATV for short.

Frege distinguished matters of being true from those of holding true – more generally, the psychological (in some broad sense) from the logical (again, in some broad sense). Following Frege we might distinguish between matters of holding forth as true – part of the psychological in this sense – and matters of being true. The business of linguistic meaning, the idea is, is matters of the first sort, not the second. Thus the contrast between sentences and thoughts, and the sort of structuring to which each is susceptible. The next step along this line of thought is to show that the means by which words achieve the recognition that they do (where to be taken as used as meaning what they do) are such as always to make room for occasion-sensitivity: the recognition a predicate would thus achieve of how a thing (or n-tuple) was said to be in using it to speak of what it does is always liable to vary from one such use to another. (For further discussion see my forthcoming a and b.)

The sentence 'Champagne bubbles' may be said, correctly, to represent champagne as bubbly. Is this not representing truly or falsely according as champagne is bubbly or not? But think of the aspect of the verb 'represent' here. Someone is asked whether champagne bubbles. He replies: "Well anyway the sentence 'Champagne bubbles' so represents it." But the sentence "Champagne does not bubble" represents it as not such. The one is no more reliable than the other. Neither lends any support to either view. Neither itself represents either truly or falsely. Similarly for 'say' and 'speak of.' To say a sentence to speak of thus and so is (roughly) to say: you would speak of that in using it on an occasion. Such does not require there to be just one way one could say things to be in speaking of them as *that*.

A sensory form would block a thought from filling its role in the phenomenon of being true. Equally, expressing as such truth or falsehood would block a sentence from filling its role in achieving recognition for holding forth as true. How to see this? One might first take a leaf from David Kaplan (*vide* Kaplan, 1989), then one from Hilary Putnam (*vide* Putnam, 1975a and 1975b). Kaplan agrees that for words to mean what they do is for them to contribute as they do to achieving recognition of the representing authored in their use. For a sentence to mean what it does is thus, for him, for it to have a 'character.' He departs from the present view in supposing its character to determine what would be said in it on any use (at least of some relevant n-tuple). On the present view, what is said, or even what is predicated, is *always* the upshot of *substantial* cooperation between meaning and circumstance. Still, he provides grist for our present mill.

A centerpiece in Kaplan's application of his distinction concerns the expression of singular thoughts – thoughts of some given object that *it* is thus and so. His aim is to defend a thesis about them: that for a given object and way for it to be, there is just *one* thought of that object that it is that way. Be *that* as it may. Anyway, singular thoughts *can* be expressed in using definite descriptions – a *prima facie* problem for his thesis. Kaplan uses character to disarm this; thereby a more general form of objection. At the reception, Alf spots Sid across the room at the buffet. Seeing what Sid (appears to be) doing, Alf remarks to his companions, 'That man who just fed the last slice of *foie gras* to his pet marmoset paints barns.' Alf thus expresses a thought, of Sid, that he paints barns. The description by which, in part, he succeeds in this identifies a person, Sid, in speaking of various ways for a thing to be: being the last slice of *foie gras*, being a pet marmoset, being one who just fed the former to the latter, being a man. It does not follow from this, Kaplan stresses, that the thought expressed does its representing in identifying anything by its being any of those ways for a thing to be. The description makes the thought expressed identifiable as the one then expressed. But it need contribute nothing to this beyond making some object (here Sid) identifiable as the one that thought is about. Which point is underlined by the fact that that object, Sid,

need not *be* as described in that description. Perhaps it is not the last slice. Perhaps it is not a marmoset but a rhesus. Perhaps the slice was not fed to it, but deftly pocketed in Sid's handkerchief pocket. And so on. What is needed for the description to achieve the recognition it is aimed at is no more than (roughly) this: that there should be an object who the speaker would then be (to be) understood to be supposing to be as thus described.

Two things need noting here. The first is the role of supposition (or close kin) in effecting the recognizability to be effected. The words Alf spoke do not speak of anyone in English. As thus spoken they purport to do so. The one this is (if any) is to be that one, if any, of whom, in the circumstances, the speaker would be to be understood to be supposing to be the one that description fit. The second is the conflict here between the demands of achieving recognition and those on contributing to a definite question of truth – to some determinate way for truth to turn on how things are. It would not have been much of a contribution to recognizability had Alf simply said, 'That object,' nor even (in a room replete with men) 'That man.' A richer understanding is called for as to *what* object. Thus the description, exploiting a particular striking bit of history which the object named *appeared* to have. The way a thing is thus described as being *is* an element in making recognizable what thought was thus expressed. By contrast, once a *thought* has been decomposed into an element which makes truth turn on how *Sid* is, and one which makes it turn on which objects paint barns, it is then otiose to seek further elements which make truth turn on further factors. We have already identified a way for truth outright to turn on how things are. Whatever other elements the thought had, they could not contribute to that. Which means, given what a thought is, that they could not be its elements. The means language provides for achieving recognition are thus the *wrong* means for constituting thoughts.

The next step is to generalize the role of supposition in achieving recognition so as to include using a *predicate* of a language to achieve recognition of what the thought expressed *predicates* of some object(s). What is the role of 'paints barns,' for example, in achieving recognition of how Alf, in those words, represented Sid as being? Here we need a leaf from Hilary Putnam's book. For many years now Putnam has shown us that the only ways we have of standing towards a way for things to be – of making it such-and-such that we were thinking, or speaking, of in thinking or speaking of things being thus and so – are intrinsically such that what it *is* we in fact thus speak of is liable to be something which is *not* what we had assumed, or even stipulated, it would be. We speak of, say, being the shortest path from one point to another. What we thus speak of is susceptible to proving something we *had* thought a shortest path could not be. Putnam shows that those thoughts available to us to think are deeply world-involving. Of course there would have been no thoughts about champagne had there been no champagne to think about. But moreover, if there is such a thing as being champagne, then what it would *be* for something to count as being that way – what would count as such – also depends on the course the world in fact has taken.

So the rule is: where we *do* speak of some way for things to be, the way we thus speak of is that way for things to be of which what would have been to be supposed, in our circumstances, as to what way this is would then have been to be supposed. If being gold would have been taken to be being a metal which was heavy yellow and malleable, then what that would have been to be supposed of is being a *metal* which, in pure state, is not yellow. Putnam's principal application of this idea was always to issues as to what words, for example, 'is yellow,' speak of as such; to what way for things to be being yellow is full stop. The aim is to generalize 'Kaplan's point' to predicates by generalizing Putnam's point to *acts* of using words to represent.

At yet another reception, Alf said to his companions, 'Sid paints barns.' He thus used 'paints barns' as meaning what it does. He thereby spoke of (someone as) painting barns – in the 'depict' rather than the 'cover' sense of 'paint.' What way for things to be would he then be speaking of? But I have already given this answer: being a barn painter. What remains to say? Many questions might remain as to which way for a thing to be being a barn painter is. Is it, for example, a way someone might be if only a weekend painter, or if he only paints converted barns (chic retreats)? Or ruined barns? Or only the stalls? Notably, is it a way such that Sid's being as he is would be a case of someone being it? Putnam's point now generalizes. The way one would then speak of in speaking of someone as a barn painter is that way of which what was to be understood to be supposed as to what way Sid was thus speaking of *was* then to be supposed correctly. Now the main point. What one would be understood to be supposing on one occasion as to what he was speaking of in speaking of being a barn painter need not be what one would be understood thus to be supposing on another. Correlatively, that of which he *did* thus speak is liable to differ from one such occasion to another.

Two morals. First, what one speaks of in *then* speaking of being a barn painter is what one would then be understood thus to speak of: that which one would then be speaking of in speaking of what being a barn painter was then to be understood to be. One thus speaks of being a barn painter as this is to be understood on the occasion. Which leaves room for how one thereby says someone to be to vary from occasion to occasion for so speaking. Second, the route from what was then to be understood as to what was thus being spoken of to what *was* thus being spoken of – and thus (via this route) from linguistic meaning to what *was* thus spoken of – is indirect enough for the service of the end of recognition to conflict with the service of that of being true. Which mandates ATV.

Such is a sketch. No room here for proof. It sketches one reason why ATV, with it occasion-sensitivity, *needs* to be the way our thought is structured. I will mention *one* other line. It focuses on a special case of representing-as: representing to be. In authoring such representing one assumes responsibility. If Alf's claim about Sid (a barn-inspired abstractionist) leads Pia to misestimate Sid entirely, she may or may not have right to blame Alf, depending on what it is Alf said in calling Sid a barn painter. For what *is* Alf to be held responsible? What responsibilities would he reasonably incur in and by *that specific act*? Well, how might that act reasonably be supposed to be contributing to pursuit, on Pia's part, of the thing for her to do? Such are questions whose answers would quite plausibly vary from act to act of calling someone a barn painter, according to the occasion there then was for doing so. Which would again yield occasion-sensitivity. But such is an idea, not even yet a sketch.

On the Linguistic Status of Context Sensitivity

JOHN COLLINS

1 Introduction

The place of context in an overall account of the semantic properties of natural language has been a dominant theme in the philosophy of language over the past 30 years. Indeed, on one way of talking, the topic is coeval with the general study of pragmatics in the various branches of linguistics. Thus it is that philosophy of language and linguistics are increasingly hard to tell apart. My aim in the present chapter is not to survey the field, nor to justify the general concern with context, although I shall indulge in a bit of both; rather, I hope to arrive at some tentative conclusions about the likely *linguistic* status of context-sensitive semantic properties.

There is a broad consensus among theorists from diverse fields and traditions that the contexts in which tokens of linguistic types are uttered systematically contribute to how the tokens are understood in ways speaker/hearers presuppose. That is, it is part of linguistic competence to exploit stable features of the occasion of linguistic acts to communicate successfully. The question I shall address is whether such competence is encoded as invariant 'open' features or variables of syntactic and semantic items or phrases. For example, the place a speaker is situated in when she makes an utterance often bears upon what the speaker says; for that relation to be linguistically encoded is for the linguistic material that delivers such a location-sensitive content to contain an item that ranges over potential locations as an aspect of its standing meaning. To give the conclusion now, I shall answer in the negative, which is just to say that the role of context in contributing to the literal meaning of utterances (*what is said*) is, in general, not itself licensed by lexical or syntactic mechanisms or items, but is, rather, due to extra-linguistic effects, on the assumption that there is no language-specific mechanism of pragmatic interpretation, but only an interpretation that goes by way of general cognition, or at least extra-linguistic cognition. Call such a view *linguistic pragmatism* (Chomsky, 1977; 2000; Lahav, 1989; Recanati, 2004; 2010; Pietroski, 2003; 2005; Travis, 2008; Neale, 2005). My notion of 'a linguistic license' is equivalent to

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

Recanati's notion of a 'bottom-up' determination of what is said by way of a fixed interpretation of the linguistic material, which stands in contrast to 'top-down' processes, which go by way of extra-linguistic processes. Thus, pragmatism is the claim that what is said is not bottom-up determined by the language alone, but is a function of both stable linguistic properties (bottom-up) and general, extra-linguistic means of interpretation (top-down).

I do not pretend that I can establish such a broad thesis here, and I shall not dwell on the various ways of spelling out the thesis and the myriad challenges to any such version of the thesis one may entertain. Instead, I shall argue that pragmatism is fully aligned with a standard approach to syntax, and should be the default view of the notion of a linguistic 'context,' *viz*., context is not a well-behaved linguistic notion, but rather a potentially open-ended way of marking the role extra-linguistic factors can play in fixing what is said on an occasion of the use of a linguistic type. In effect, the role of context in determining what is said is a feature of top-down processes. I shall focus on apparent covert context sensitivity in weather predicates as they occur in reports such as *It's raining*.

2 Terms of Debate

2.1 Meaning, Truth-Conditions, What Is Said*, and so on*

Let *meaning* designate whatever semantic properties a linguistic expression (word, phrase, sentence) invariantly possesses in the sense that such properties make a constant contribution to the understanding a competent user of the expression exploits. *Pro tem*, let meaning in this sense be potentially a very thin notion, perhaps no fatter than a set of syntactic constraints on interpretation. A syntactic constraint is a property of sentence that can be specified formally, without reference to general conceptuality, but which allows and disallows certain interpretations. Many examples will follow.[1] The crucial point is that *meaning* is a purely linguistic notion, a property of the language itself that is not determined by context of use or what a speaker intends to communicate; indeed, we might say that meaning is what speakers' intentions cannot trump, but default track. This is why meaning is invariant.

I take utterances, not sentence-types, to have truth-conditions. An argument for this claim is required, for it can seem that *if* meaning is invariant truth-conditional contribution, then that a sentence-type has a meaning suffices for it to have truth-conditions. So-called *minimalists* claim just that: sentence-type meaning suffices for invariant truth-conditions, regardless of whether such a content is apt to be communicated by a token of the type (Borg, 2004; Cappelen and Lepore, 2005). Whatever the truth of this claim, the inference advertised is invalid, that is, minimalism does not get to be true merely by a deft arrangement of distinctions. The contribution a constituent item of a sentence makes to the sentence's truth-conditions may fail to be determinate. In this scenario, linguistic meaning will underdetermine truth-conditions. This claim, that admits great variation, is typically dubbed *contextualism* or pragmatism (I prefer the latter label as already noted) on the understanding that the extra-linguistic ingredient that, along with linguistic meaning, fixes the truth-conditions for an utterance is some relevant selection of contextual factors to which speaker-hearers are sensitive (person, time, addressee, etc.). I shall argue in the following that a fairly radical version of pragmatism is correct, and can be upheld on strictly linguistic grounds. For the moment, I am merely flagging the position as one that is consistent with the existence of literal linguistic meaning *and* truth-conditional content, the position just does not identify the two.

Content (or truth-conditions) is often expressed in terms of *what is said* by an utterance, which stands in contrast with what is communicated, which might involve all kinds of implicature, irony, and other figural effects. *What is said* is what a speaker can intend another linguistically competent hearer to understand without any information other than the shared situation and a shared language. Of course, it doesn't follow that, on any given occasion, communication will be successful, or is even a notion that admits precision where natural language is concerned. Still, it is a truism that knowing the meaning of a sentence *s* (being linguistically competent with respect to *s*) allows one to say *p* with *s* such that one can expect any suitably placed person to understand that one said *p*. This is the notion of what is said, and can be recognized as a crucial aspect of language independent of the epistemology and metaphysics of communication and linguistic publicity.[2]

So, here is a rough picture of the relevant semantic distinctions. Utterances have truth-conditions, which amount to what the speaker *says* on the occasion of utterance. There is a purely linguistic contribution (meaning) to these truth-conditions, which, as things stand, constrains what is said to some degree in the sense of allowing and disallowing literal construals of the linguistic material without fixing any definite construal. I shall hereafter explore a particular route to settling on what the degree of constraint is by way of appeal to syntactic structure. First, let us fix on what is and can be meant by *context*.

2.2 Context

There are (at least) four respects in which the notion of context might be employed in regard to an utterance. First, there is the perfectly general way in which more or less anything may be related to some particular circumstances. I take such a notion of context to be of no peculiar linguistic interest. Context here merely serves to present the utterance in a certain setting without its content being affected, either as a whole or in regard to specific lexical items or constituent phrases. Of course, a specification of a context will trigger various presuppositions and implicatures, but these may be triggered anyway by mutual knowledge without any linguistic aid. This language-independent aspect of context in the most general sense stands in distinction to the following three notions of context.

A second notion of context is familiar from work in formal semantics going back to Montague's (1974) seminal writings and advanced most fully by Kaplan (1989). A context here is essentially a formal abstraction, which we can represent as an *n*-tuple of items drawn from the 'world' such that each item serves as a value for a constituent of the utterance or affects the overall content of the utterance (when suitably regimented). Thus, traditionally, speaker, addressee, time, place, *et al*. find their way into the context and serve as values for (*inter alia*) pronominal items and various functional morphemes (such as tense). A great deal has been written about this idea of a context; my concern, though, is not to renounce or finesse the notion, but largely to take the idea for granted, or at least what I take to be the fundamental insight underlying the idea. If we assume that one way of specifying the content of an utterance is to provide its truth-conditions, then such truth-conditions cannot be specified solely from the knowledge of the meaning of the linguistic type. Much if not everything we say with our utterances is variable in depending on factors that potentially shift from one tokening to another of the linguistic types (tense, personal pronouns, etc.). The present idea of a context, therefore, is simply a way of generalizing over such variability. In this light, a context is simply a component of the truth-conditions of utterances. So understood, it really doesn't matter if we theorize a

context as a set-theoretical object (an *n*-tuple) or let the information be specified as the antecedent of a conditional, with its consequent being the truth-conditional specification of the contextually specified linguistic type. That difference is one of internal machinery in the semantic theory, not a difference in the phenomena. Both approaches have the burden of saying just what information or values enter into the context. The fundamental insight, therefore, is that utterance content is variable over contextual factors in a systematic way under a linguistic license in the sense that values of linguistic items must be in the context, if the utterance is to have truth-conditions.

The items that go into a context in the above sense are those that obtain on the occasion of utterance. There are other variable extra-linguistic factors, though, that bear on truth-conditions but do not obtain on the occasion of utterance. This is a third sense of *context* that pertains to how utterances are assessed or evaluated. For example, a future tense utterance (*Bill will die before he is 80*) will be made true or false by future events, not those that presently obtain; thus, the truth-conditions of such utterances cannot be fully specified in terms of the here-and-now context of utterance alone, but must also include elements of the type that can feature in a context, but have relevant tokens that do not obtain on the occasion of the utterance (e.g., a future time that fixes the truth of a future tense utterance is distinct from the time of utterance).

Appeal to this third notion of context often goes under the label of *relativism* and there is much dispute about whether the context sensitivity of various classes of expression is due to the (here-and-now) context of an utterance or that to which its truth-value assessment is relative. This chapter will not dwell on the standing of so-called relativism either in its own right or as contrasted with some species of 'contextualism' or 'pragmatism.'[3] My only concern is for the potential linguistic licence of the contextual valuation of linguistic material, regardless of whether the relevant contextual factors pertain to the here-and-now or not. I shall, though, turn to one relativist rejoinder to pragmatism in §6.

A fourth sense of *context* is more resistant to a precise specification as it pertains not to specific features of a shared situation or a recognizable point of assessment (a judge or an experiencer), but to a shared understanding of how a word or phrase might be intended. *Polysemy* is an oft-used term for the phenomenon I have in mind, but I here do not intend to prejudge the standing of the effect in terms of its scope and possible constraints. It seems, at any rate, that every predicate save for those with a stipulated meaning is subject to a wide variety of interpretations any of which might be literally meant if the occasion is obliging. Take, for instance, Travis's (2008) much-discussed example of *The leaves are green*. As a photographer, one might be interested in leaves that merely look green, including painted ones (Antonioni had a field in a south London park painted green for *Blow-Up*), but not as a botanist. The point here is not that *green* and other color predicates are lexically ambiguous – they appear not to be – but that, in general, things *count as* satisfying a predicate or not on the basis of shifting understandings of what would count as the thing being so and so on a particular occasion. It is moot whether the variety is open-ended and, if not, what the constraints are on what can count as what.

As advertised, I shall conclude that the fourth sense of context is the one generally appropriate for the determination of what is said. I shall not argue for this directly, though, but only via consideration of the problems that beset the thought that context is a linguistically encoded feature up to the fixation of what is literally said with an utterance.

2.3 Syntax and Context-Sensitive Truth-Conditions

Let us assume that context in at least one of the latter three senses adumbrated above enters into the determination of truth-conditions, and so is a phenomenon an adequate semantic theory for natural language must apparently accommodate; that is, to know a language is to know how to exploit context to say this or that, or, if you prefer, to know that context is exploitable in such and such ways in order to say this or that. My focus will be on the putative syntactic accommodation of contextual factors. To finish off my outline of the terms of the debate, therefore, I shall say something very general about syntax and its relation to truth-conditions.

Naïvely, one might start with the idea that the possessor of truth-conditions is a sentence-type individuated by surface syntax. It is common ground, however, that this will not do for a range of familiar reasons, including what I shall call *overtly context-sensitive expressions*, such as personal pronouns, temporal and spatial adverbials, demonstratives, and so on, which were the chief concern of Montague (1974) and Kaplan (1989). The problem is that what a personal pronoun such as *he* contributes to the truth-conditions of its host sentence will be determined by who the speaker has in mind to refer to by *he*, which will not be invariant over uses of the type. Thus:

(1) 'He is tall' is true iff he is tall

does not record the truth-conditions of the quoted sentence, for it has no determinate truth-conditions in the absence of an identification of who *he* refers to, which the right-hand side of the equivalence does not do. Otherwise put, the form of (1) does not in general fix the theorist's *he*, as it were, as being co-referential with the quoted *he*. There are ways of remedying the problem, as we shall see, but however it is achieved, some departure from the naïve approach is entailed. Let us go the whole hog, then, and say that truth-conditions are a property in the first instance of a *logical form*, leaving it open for which constructions, potentially every one, a valuation of items of the form by context is required for the form to possess truth-conditions, that is, logical form alone may or may not fix truth-conditions by itself.

> *Logical form*: The logical form corresponding to a sentence/utterance is a structure that disambiguates a surface form and licenses determinate values and composition principles for the constituents of the structure such that they make an invariant contribution to the truth-conditions of sentences/utterances of the form.

Traditionally, some such notion of logical form has been borrowed from various systems of formal logic and applied to natural language without real interrogation of how logical form relates to surface form or natural language more generally; that is, logical form is the theorist's language in which the phenomena of meaning as found in the language are described or explained. There is a more constrained conception, however, where 'logical form,' or 'LF,' refers to a level of syntactic structure that realizes the relevant properties of the logical structure under conditions that pertain to natural language syntax generally (May, 1977; 1985; Chomsky, 1977; 1981; Higginbotham, 1985).[4] It is this latter notion I shall have in mind hereafter. Although many of the issues to be broached will not turn on the difference between the traditional notion and the one that prevails in syntactic theory, the distinction is crucial in the following sense. If there is an independent notion of syntax that

enters into fixing possible truth-conditional contributions of linguistic items, then if a notion of logical form cannot be identified with a syntactic level in this sense, then an interface issue arises of how the theorist's logical form is tracking the syntactic properties. Put epistemologically, the best, or at least a very good, justification for a theoretical claim of logical form is precisely that it is evidenced in the syntax. Excuse the abstraction; concrete examples will follow.

Our concern, then, is just this: What is the general relation between logical form structure and context-sensitive truth-conditions? Answering this will give us a fundamental take on context sensitivity as a semantic property of natural language. The short form now is that context sensitivity is not a syntactically coded effect, but lies outside of language proper based upon speaker intention.

3 Overt Context Sensitivity

Let us assume that expressions of a language divide between those that take different values relative to certain contextual parameters and those that take constant values. The sharpness of such a distinction is moot, but there appear to be paradigm cases of each class, such as personal pronouns and spatio-temporal adverbials (*here*, *tomorrow*) on the context-sensitive side and quantifier expressions (*every*, *some*, etc.) and other functional morphemes (tense, *-ing*, etc.) on the other side. Proper names are a controversial case, but let's assume that they are context-insensitive. An adequate semantic theory would feature primitive clauses of some form or other whose content is simply that the value of the name is some object (leaving to one side ontological scruples about what an object is). For example:

(2) a **v**(Bob, *Bob*)
b $[[\text{Bob}]] = \lambda x[x = \text{Bob}]$

It is a common approach to treat pronouns of various stripes as if they were names, save relative to a context. So, whereas *Bob* picks out Bob come what may, a pronoun such as *he* also picks out some definite object, but only relative to a given occasion of its use. The idea is intuitive enough and does reflect features common between names and pronouns, such as rigidity and neutrality over background information. There also appears to be a straightforward way of implementing the idea. In essence, the proposal is that a context-sensitive item is akin to a free variable syntactically encoded via an index and assigned a value relative to an assignment, not as a constant function. Something along such lines is the current orthodoxy in the semantics literature (cf., Montague, 1974; Kaplan, 1989; Fiengo and May, 1994; Larson and Segal, 1995; Heim and Kratzer, 1998; Büring, 2005). Let me first flesh out the view, focusing on a proposal by Larson and Segal (1995), then I shall turn to its problems as a semantic proposal about a fixed linguistic mechanism licensed by logical form.

Following standard post-Tarski (1936/1983) approaches for the semantics of formal languages, variables are taken to be numeral indexes (or to have such indexes – the difference doesn't matter) such that a variable takes as value whatever object is in the ordinal position that is the same as the numeral index of a sequence of objects. So, a variable takes a value relative to sequences of objects drawn from the domain, where variables are distinguished by their indexes, but all remain equally general because, for every sequence position, every object occurs in that position in at least one sequence. The principle works much the same with assignment functions

that dispense with sequences, that is, both methods deliver the same truth-conditions. There is an obvious problem, however, with treating pronouns as free variables. Free variables have a universal or indefinite semantic significance in the sense that, for every object *o*, there is a sequence σ that has *o* in its *i*th position, for all positions *i* (*mutatis mutandis* for assignment functions). A pronoun, however, is not so general: on a given occasion of use, it picks out a definite object. The problem might be put as follows: a variable does not by itself differentiate between objects that might serve to satisfy the host expression – the variable is effectively syncategorematically interpreted in union with its host predicate. Larson and Segal (1995), in response to a problem of this kind, propose that the speaker of an indexical, such as a pronoun, selects a sequence that contains the relevant objects in the relevant positions, but this is a metaphor in the sense that the speaker does not select a sequence, but merely the relevant objects. The same problem arises for assignment functions. Larson and Segal appeal to sequences, I take it, because they capture the generality of indexicals at the type level; the problem is then how to resolve that generality at the token level, a problem that *cannot* arise for variables as satisfied by sequences. Going over to assignment functions does not help. In effect, the model would be one of ambiguity resolution, where the indexical is ambiguous between assignment functions; what the speaker's intention provides is a resolution to the ambiguity in terms of a selection of a unique assignment function from potentially infinitely many options. The problem now, of course, is that a type indexical is precisely not ambiguous as a linguistic item; it is, rather, simply indefinite, which is precisely what sequences capture. The thought that a speaker sheds, as it were, infinitely many assignments in order to select just one assignment faces much the same problem as the sequence approach, for it remains unclear why any options whatsoever are entertained save for the immediate option of the referent being fixed by the speaker's intention. What this misses is the generality of the indexical, but that is missed by selecting a unique assignment too. The generality and definiteness of an indexical can't be squared by treating the indexical as if it were a variable, for a variable is never definite.[5]

There is another aspect to the problem of treating pronouns as variables. We assumed that pronouns come with indexes. Starting with Chomsky (1965), the use of indexes in syntactic theory became the norm, and they certainly are a useful way of encoding deictic and bound readings of pronouns; that is, an index unmatched with another index is read as getting a value from the context (deictic) and an index that is matched with a higher index has a value that covaries with the higher index (bound).[6] Thus:

(3)a Every philosopher loves himself/herself
b Every philosopher thinks he/she is a genius

(3a) is unambiguous with the single Quinese paraphrase:

(4) Every philosopher *x* is such that *x* loves *x*

(3b) is ambiguous between a bound and free construal of the pronoun:

(5)a Every philosopher *x* is such that *x* thinks *x* is a genius
b Every philosopher *x* is such that *x* thinks *y* is a genius

The value of the pronoun on the free construal is contextually determined on the occasion of a tokening of (3b), Kant or Plato, say. The difference may be codified via indexes:

(6)a $[\text{Every philosopher}]_i$ thinks he_i is a genius
b $[\text{Every philosopher}]_i$ thinks he_j is a genius

Here is not the place to venture into the complex field of binding, but it is well to rebut one potential line of reasoning. The dilemma posed for the standard approach of identifying indexical expressions with free variables is that it is the speaker's intention to refer to *x* that fixes *x* as a definite value of a pronoun, which is not a feature that is encoded semantically or syntactically. To be sure, one can stipulate a relation of the kind Larson and Segal propose, but it merely recapitulates the extra-linguistic intention rather than grounds or constrains it. One might think, however, that since pronouns and other complex phrases syntactically feature indexes, then the job of a theory is just to provide values for the indexes in the relevant manner. In other words, the free or bound status of variables *is* encoded in syntax via indexes, so the identification of pronominal context sensitivity with free variability is not sunk, even if the semantic valuation does proceed by way of speakers' intentions. The problem with this thought is the assumption that indexes are kosher syntactic features in the relevant sense.

On the face of it, indexes are the *theorist's way* of marking joint or disjoint construal rather than an independent feature that constrains or fixes what construals are possible. If it were otherwise, then an assignment of indexes to the relevant expressions within a structure would be independent of any intention of joint or disjoint construal. In that circumstance, however, there is no way of fixing one index to be the same as or distinct from another index within a structure just by the properties of the individual indexed items or the structure as a whole, *where* there is an option for joint or disjoint construal. Where there is no such optionality, then indexes are redundant anyway, assuming that some such interdiction is determined by independent structural conditions. Thus, indexes can mark optional construals, but not independently fix one option over another.

The ultimate truth of binding, as it were, is a matter beyond my present scope. The current conclusion is merely that the facts of context sensitivity do not simply fall into line with a naïve theory of indexation that treats pronouns just like free variables. What a speaker intends to refer to is ground level for a *general* account of what pronouns contribute to what is said by an utterance. A theory of meaning in the narrow sense of a theory that specifies what language alone contributes appears to do no more than delimit options of reference and fix necessary construals, all of which appears not to rely upon a system of indexation.

4 Covert Context Sensitivity

Context sensitivity is not restricted to the construal of overt linguistic material. It also appears that the construal of tokens of many constructions depends upon contextual factors that are not explicitly encoded in linguistic material; that is, *if* pronouns are explicit variables, then there appear to be implicit or covert variables as well. *Pro tem*, we may specify the idea in perfectly general terms without appeal to any particular theoretical assumptions. Let us borrow some terminology from Perry (1986), but employ it for our own ends:

> *(UC) Unarticulated constituents*: The stable propositions expressed by sentence tokens (relative to context) of particular types include constituents that are not values of any overt linguistic material occurring in the token.

UC leaves open the provenance of the relevant constituents, whether, that is, they are values of *covert* syntactic variables, semantic effects of lexical meaning, or features of pragmatic

enrichment. UC is useful simply for picking out a range of otherwise diverse phenomena. So, consider weather reports, such as *It's raining*. Tokens of the type appear to express propositions that feature locations in the sense that the truth-values of the tokens depend on how things are at some particular location, that is, some other locations are excluded as truth-conditionally irrelevant. Also consider so-called *predicates of personal taste*, such as *Liquorice is tasty*. Tokens of the type express propositions that concern a particular person's taste, that is, the truth-value of the token turns on how some person judges liquorice as opposed to how liquorice is anyway. Many other examples could be offered, but these cases serve to exhibit some general features that will be my concern.

First, I shall offer some general grounds for why the bare phenomena UC directs us towards should not lead us to populate syntax with covert items that may thus be valued by the unarticulated constituents of the propositions expressed. I shall then consider weather reports in particular as a case that supports this general claim. To finish, I shall briefly consider a relativist rejoinder to the considerations offered.

4.1 The Syntax of Covert Items

A central feature of generative syntactic theory is that it posits covert items and relations in its analyses of linguistic material. According to the approach, how a sentence appears in terms of its phonology/morphology is a set of properties of a more complex structure organized by general principles it is the task of the theory to specify. On the face of it, UC seems to be a prediction of the generative approach, for on the assumption that syntax places structural constraints on what a sentence may mean, then such constraints need not be overtly encoded. Thus, if weather reports are constrained to be locative, and no locative phrase need explicitly occur in a weather predicate for it to occur in a grammatical sentence, then it might well be part of the covert syntax of the general clause type to feature an item that is locatively construed (*mutatis mutandis* for other cases). Even though such reasoning is fine as far it goes, real caution is required if one is minded to generalize the reasoning to every case going, as Stanley (2000) explicitly commends. There are two basic desiderata that need to be satisfied, what I shall call *syntactic license* and *semantic constraint*.

> (SS) A would-be syntactic item must be licensed in the sense that it invariantly affects the grammatical and interpretive status (if distinct) of the structure as a consequence of a general principle.
>
> (SC) A semantic construal of a structure counts as evidence for the structure having a syntactic feature F only if the construal is necessary.

In simple terms, SS enshrines the thought that syntax is not a receptacle for whatever semantic features are deemed stable; a syntactic item must bear upon the *syntactic* status of the host structure. Methodologically, of course, SS operates only in light of some syntactic assumptions, which may always be questioned, but the basic idea is uncontroversial, for if the presence of a covert item did not affect the status of the structure, there would be no syntactic basis for the item at all. Put differently, SS demands a syntactic rationale that might be distinct from any semantic rationale. For example, it is standard to treat infinitival clauses as occurring with a covert subject PRO, which may be bound or 'controlled' by a higher phrase, if embedded, or otherwise be 'arbitrary.' Thus:

(7)a Mary$_i$ tried [PRO$_i$ to leave]
b Mary asked Sam$_i$ [PRO$_i$ to leave]
c PRO to smoke is foolish

Assume a principle that states that a full verbal projection features all of the verb's arguments, even if some or all of them end up occurring overtly outside of the projection. The positing of PRO is one way of satisfying such a principle that has its role to play in explaining a host of phenomena. There is, though, an apparent independent semantic rationale for positing PRO, *viz*., the infinitival has an understood subject. For example, with *Mary tried to leave*, we cannot understand there being no agent of leaving, as if someone's leaving is not even in the offing – that is gibberish. So much, though, does not explain the properties of PRO. One might think, for example, that PRO is like a variable, occurring bound in (7a–b) and free in (7c); such would satisfy the semantic rationale and align PRO with overt pronouns. As it is, though, arbitrary PRO does not occur bound, even when embedded:

(8) Mary asked Sam whether [PRO to smoke is foolish]

(8) does not express Mary's asking whether Sam's smoking would be foolish. The status and interpretation of PRO remain controversial; the current point is simply that positing PRO has a syntactic rationale independent of its construal, and that properties of its construal appear to be peculiar in the sense of not being aligned with overt phenomena.

SC offers a related constraint: even if one is solely considering semantic evidence, the relevant readings must be necessary ones, for the syntax itself is invariant by assumption. For example, (7a) has the single reading under which Mary is doing the leaving, as opposed to an arbitrary other person. Such evidence tells us that the subject position of the infinitival cannot be occupied by something akin to a free variable. As another example, consider familiar adjunct ambiguity:

(9) Mary saw the elephant from Africa

The adjunct prepositional phrase *from Africa* may modify the DP *the elephant* (the elephant is African as opposed to Indian) or the VP *saw the elephant* (Mary may have seen the elephant – African or Indian – across the Israel–Egypt border). The adjunct *cannot* be read as modifying the subject *Mary*. Such a restriction on possible readings tells us that the adjunct is merged in the verbal domain and so cannot selectively modify the subject that occurs outside of the domain (at the 'surface').[7]

There are, to be sure, trickier cases. Consider optional binding phenomena discussed above, such as:

(10) Bill thought he was a genius

(10) is two-ways ambiguous as (9) is. The ambiguity alone does not tell us if the two readings are syntactically encoded, let alone how they are. Remember: SC only says that semantic phenomena count as evidence for syntactic structure, if the phenomena mark a necessity; it does not say that all readings must be syntactically accommodated. So, the ambiguity of (10) might be syntactically unresolved, or be so resolved in ways that do not treat the pronoun as a free variable.

Let us now apply the morals adumbrated to the case of weather reports. Many different phenomena are germane, even with so thin a diet; I shall focus on the most salient data.

4.2 It's Raining *Again*

On the 'standard view,' as Recanati (2010) calls it, the problem of weather reports is how to explain their obligatory definite locative construal; that is, why, for example, *It's raining* is construed as being about a definite location, as opposed to somewhere or other (indefinite) or no particular place at all (*punkt*). The answer provided by the standard view is that the relevant lexical entries contain a locative argument position, a covert variable on some readings, which is valued for locations. So, for example:

(11) $\lambda l \lambda e[\text{rain}(e, l)]$

This would-be lexical entry for *rain* tells us that *rain* picks out an event occurring at a location. Notwithstanding real disagreement over detail, at least Perry (1986), Stanley (2000), Taylor (2001), Corazza (2007), and Neale (2007) agree that weather reports are construed as definite locatives as a matter of lexical understanding, or fixed truth-conditions, not pure pragmatics. In some sense, therefore, they are all committed to (11) as the right lexical entry.[8] In fact, though, no one serious could possibly think (11) records the relevant property of the lexical entry of *rain*, for *rain* is obviously usable outside of weather reporting, where no location at all, definite or indefinite, is relevant. Still, the thought is that a locative argument is saturated in weather reports as a matter of the fixed logical form of the construction rather than pragmatic enrichment (an argument or position is said to be saturated if its value is required for the interpretation of the host predicate). So, ignoring tense, the logical form of *It's raining* is:

(12) $(\exists e)[\text{raining}(e) \wedge \text{Location}(e, l)]$

The kind of analysis exemplified in (12) has at least two things going for it. First, like an overt pronoun, we can take the locative to be contextually valued, which would explain its putative obligatory definiteness: if the argument is contextually valued, then it must be valued as a definite location. Second, again like an overt pronoun, the locative argument can apparently be bound. Consider:

(13) Wherever I go, it rains

This appears to have the obligatory reading

(14) Every location l is such that, if I go to l, it rains in l

Against the standard view, Recanati claims that the lexical entry for *rain* lacks any argument position other than an event position invariant over all predicates:

(15) $\lambda e[\text{rain}(e)]$

A relevant weather report, therefore, might consist simply of the existential binding of the event variable (ignoring tense):

(16) (∃*e*)[raining(*e*)]

The immediate problem with this proposal is that it fails to capture the apparently obligatory definite construal of weather reports. When one utters *It's raining*, one surely doesn't *say* that there is a raining event taking place (somewhere or other). One cannot help, it would seem, but to speak of one's present location; or at any rate, a location otherwise contextually salient, such as the location of one's addressee. For precisely this reason, as explained above, the 'standard view' represents the lexical entries of meteorological predicates as containing a locative variable. Recanati offers a complex response to this challenge, but here I shall only be concerned with his claim that scenarios are readily imaginable where weather reports have indefinite and even *punkt* construals, just as (15) predicts.

Recall that, according to the 'standard view,' meteorological predicates have a locative argument position that must be filled, if an utterance hosting the predicate is to be semantically acceptable. Such a condition would explain the definite construal of weather reports being apparently mandatory. The view, though, appears to make a strong prediction: *punkt* construals of weather reports are unavailable; and while indefinite construals might be available, they would have to involve a quantification into the locative position. Recanati (2002; 2004; 2010) offers the following kind of scenario as a counter-example to this prediction:

The Weatherman Scenario
The Earth has suffered a massive ecological catastrophe, the chief consequence of which is that rain no longer falls. The remnants of humanity have decamped to an underground bunker. Fortunately, before the survivors were forced from the surface, they placed sensors all over the planet in order to detect the hoped-for future rainfall. The detection mechanism, though, is not that sophisticated; the console in the bunker's monitoring room, manned by the weatherman, lights up just if rain falls on any of the sensors, but it doesn't immediately record which sensor is so affected. To figure out the identity of the relevant sensor requires lots of laborious calculation. One propitious morning, the light on the console begins to flash. The weatherman excitedly cries to his colleagues, 'It's raining!'

The intended intuition elicited here is that the content of the weatherman's utterance is *punkt*, for neither he nor his audience know of the location of the rain; for sure, they know that it is raining *somewhere* or other, but this reveals some knowledge about the nature of rain, not what is saturated in the linguistic content. The weatherman, we may say, has evidence of rainfall, but is not yet making a claim about its location. Thus, the logical form of the weatherman's report would appear to correspond to (16), which lacks the putative obligatory locative argument position.

It is important to note that the weatherman scenario is *not* intended as an argument for the possibility of it's raining at no place at all, as if there could be locationless rain, as it were. If it is raining, then it must, indeed, be raining somewhere, whether or not one knows where. The point of the scenario, at least in my hands, and Recanati's (2010, pp. 88–90) too, I take it, is to show that there are *punkt* readings of weather reports that appear to require no variable binding. Thus, in the absence of a good reason to think that some kind of covert quantification is in play, the scenario militates for (16) being the appropriate logical form. The fact that the weatherman would acknowledge that it must be raining *somewhere* does

not, in this light, belie (15) as a depiction of the lexical content of *rain*. It is the weatherman's wider knowledge about rain that licenses the inference to its raining somewhere, not an aspect of the lexical content. His understanding of the metaphysics of rain – that it is locational – overrides the mere semantic content that there is a raining event as determined by the fixed semantic properties of the linguistic type. That it is raining iff it is raining somewhere does not entail that *It's raining* features a locative argument as an aspect of its syntax or semantic content. There is much else to say here, but it is best delivered by way of the consideration of an objection.

As presented so far, Recanati's weatherman reasoning suffers from a decisive objection. The weatherman scenario is perfectly coherent, but the weatherman's weather report is not genuinely indefinite, let alone *punkt*. To be *really* indefinite, the truth-conditions of the utterance must be sensitive to every location: if it is raining *anywhere*, then the utterance is true. If some set of locations is constitutively excluded as being potentially determinate of the truth-value of the utterance, then the complement of the set of such locations will constitutively include all and only the truth-determining locations. So, in a broader sense, the utterance will not be indefinite, still less *punkt*, but definite relative to the relevant complement set of locations. In concrete terms, the weatherman's utterance is definite as regards locations on Earth, for neither the weatherman nor his audience would take the weather on another planet to be truth-conditionally relevant. The weatherman's utterance is definite after all, albeit in a broader sense than we might at first imagine. Such considerations suffice, I think, to confound the weatherman scenario's import as presented, but they invite a recasting of the scenario.

One can recast the scenario in two different ways that undermine the objection just raised. First off, consider a scenario just like the original weatherman one, except that the weatherman is entirely clueless about where he is. As far as he knows, he could be on Earth, Mars, or in a spaceship moving at near light speed; just so, he hasn't a clue where his sensors are scattered. In this scenario, the weatherman may still legitimately cry, 'It's raining,' when his console flashes, but there is just no definite location, no matter how expansive, that may serve as the location that satisfies the weatherman's report; at any rate, the weatherman certainly cannot exclude any location as truth-conditionally irrelevant for his utterance, for he doesn't know his own location or the location of the sensors in order to exclude any other location. This 'ignorance' scenario, I think, clearly shows that weather reports do not need to be construed definitely.

Second, consider an 'intergalactic scenario,' just like the first weatherman scenario save that the sensors are dispersed throughout the universe, not just on the surface of the Earth. If the objection to the initial weatherman scenario is merely that the weather report is definite after all, because the Earth constitutes the definite value of the weather report on the grounds that non-terrestrial locations are excluded as truth-conditionally irrelevant, then the intergalactic scenario would appear to spike the complaint, for no locations are excluded as truth-conditionally irrelevant. Arguments can be had here. Extrapolating from remarks by Neale (2007, p. 370, n. 77), Perry (2007, p. 545), and Korta and Perry (2011, pp. 112–113), one may suggest, for instance, that the entire universe remains a location, so the intergalactic scenario still doesn't provide a case where the weather report is construed as lacking a locative argument position.[9] The force of this objection is questionable.

The intergalactic scenario satisfies the just demand that a non-definite construal shouldn't exclude any space–time point as being truth-conditionally irrelevant. The riposte now is, in effect, that every location together amounts to a location. This is not a silly

thought, but nor is it obviously true. Consider two cases. One may imagine a physicist saying, 'It is cold here,' intending to speak about the temperature of the universe. Of course, we also have the age-old philosophical query, 'Why are we here?' One would miss the import of the philosophical query by responding with, 'What, you mean as opposed to there?' The query is not intended to be about some location as opposed to another, but all locations as such. Similarly, the physicist is not refuted by one's appealing to the core of the Sun, for he has in mind not this or that location, but all locations taken as a sum. Even granting, though, that the whole of space–time may constitute a location, the point of the initial complaint is answered: the weather report is non-definite to the degree to which no location is excluded as not being *here*. It would cease to be non-definite were we to imagine some location outside of the universe whose climate was irrelevant to the truth of the weather report. Fine. Now we just change the scenario again to include the multiverse, if you will – and so on and on. In short, establishing a genuinely non-definite reading of a weather report does not involve severing the very idea of a location from the interpretation of meteorological predicates; it suffices that no location is excluded by the reading.

The question remains, though, whether either the 'ignorance' or the 'intergalactic' scenario admits *punkt* construals of weather reports. One line of reasoning for a negative answer is that in both cases we can render the weathermen's respective utterances as *It's raining somewhere*, which apparently amounts to an existential quantification into the locative position of the predicate; indeed, the original weatherman scenario may be so rendered too. So, whereas in the above scenarios the weathermen do not know where it is raining and so do not make claims about that definite location, they still may be understood as making a claim about some or other location, namely the one where it is raining. A defender of the 'standard view' may now claim that the locative position in the meteorological predicates can come in two forms: either contextually valued, as in the quotidian cases, or implicitly existentially bound, as in the *outré* cases just discussed. So, the logical form of the non-definite cases just discussed is rather indefinite, with a bound locative position, instead of being genuinely *punkt*, with no locative position at all.

Independently of further considerations, I readily concede that there is no knock-down argument against this reasoning in favor of the monadic account of *rain* offered by Recanati. That said, the argument suggested bolsters the 'standard view' more than it defeats the monadic view, for the argument as presented simply assumes that the fact that raining must take place at some location is built into the semantics or lexical entry for *rain*. The existence of such a constitutive relation, though, is precisely what is at issue. The opponent of the 'standard view' is not *obliged* to produce a *punkt* scenario, but only to cast doubt on whether readings of weather reports are best explained in terms of saturation of locative positions. Indeed, given the metaphysical connection between rain and its location, the opponent might well happily acknowledge that no scenario could possibly force a clearly *punkt* construal, but by itself that does not show anything about the status of the would-be locative argument position. What is required for progress here is a syntactic or lexical account of the putative locative position. That is, if it could be shown that *rain* carries a locative argument as part of its lexical content, then that would show that the locative metaphysical character of rain is linguistically encoded as opposed to being an aspect of our general metaphysical understanding of raining events that always overrides a *punkt* semantic construal, which is all the linguistic properties fix.

It is also worth noting that the utterances of neither of the weathermen may be properly construed as *It's raining where the signal came from*. The respective weathermen believe that or have evidence for it, but do not *say* that. What they say would be true, and be taken to be

so, if the signal was a false alarm, but, serendipitously, it was in fact raining elsewhere. Remember, the weathermen have no way of knowing just where the signal is coming from; they merely have evidence that it is raining.

4.3 Quantifying In

The second strand to the 'standard view' is that meteorological predicates *must* contain a locative position because we can quantify into it. If there were no such position, then the quantifications would be, contrary to fact, illicit. The relevant data are exemplified in (17) (here, (13) is repeated as (17a)):

(17)a Wherever I go, it rains
b Every location *l* is such that, if I go to *l*, it rains at *l*

The exhibited reading of (17a) is enabled by an implicit position licensed by *rain* being bound by the prefixed apparent quantifier phrase, or so claims the 'standard view.' That is to say, *It rains* contains a locative variable in non-quantificational constructions; hence it is that it can be bound in (17a). If this is so, then we supposedly have a criterion for the presence of a variable item, *viz.*, a bound reading is available. I have depicted the bound reading in (17b) as if the variable associated with *rain* is *simple*. This need not be the case, of course. Instead, following Stanley (2000), one might think of the variable *l* as a stand-in for a complex – $f(x)$ – that is contextually valued in a twofold way.[10] The variable x may be bound or valued contextually, in the present case as a location (an element of the context), and the function f is valued (in context) as a function from the location value of x to the locations where it rains (*mutatis mutandis* for the variable complex putatively associated with DPs). So, $rains_{f(x)}$ takes as its value the set of locations where it rains.

Before assessing the argument offered, it is well to note that the principal cases to be discussed, exemplified by (17a), appear to involve adjunct free relatives (e.g., *wherever I go*), whose syntactic status is the subject of much dispute. We can argue about whether the free relative as it occurs in (17a) binds some kind of argument position, but such a proposal is not underwritten by standard movement conditions, such as quantifier raising (QR) or the like, that are typically taken to be diagnostic of quantification in syntax. This is obvious enough, for the movement is perfectly overt (the relative clause is moved from a position modifying *rain*) and no 'surface'-level properties appear affected by the free relative being fronted or not, that is, it makes no difference to the interpretation whether the relative clause appears at the front of the sentence or as appended to *rains*. In effect, therefore, the syntactic issue is whether the free relative satisfies the selection requirements of the matrix verb *rains*, which if so would provide evidence for a locative argument position, that is, the relative clause would not be an adjunct. That, however, is precisely the issue in dispute, and we have seen no evidence to think that the locative construal of *rain* is a matter of its syntactic projection; that one can append a locative relative clause tells us nothing, since the clause itself may be an adjunct, as it appears to be. It is still open, of course, for one to think that, when fronted, the phrase does bind a lower variable position, and that this is a syntactic affair, but I know of no reason to postulate such an apparently *ad hoc* syntax.

(17) does appear to pattern *rain* with other relational items (nouns, adjectives, and verbs), which lends weight to the thought that *rain* itself expresses a locative meaning however syntactically realized. Consider the following cases:

(18)a For most Arabs, America is the enemy [of the Arabs]
b Everyone prefers a local [to them] bar
c Whenever the copy-editor made a mistake, the proofreader would notice [the mistake]

Questions arise here concerning implicit arguments and their potential syntactic projection, whether in nominal, verbal, or adjectival domains. Note, however, that the bare idea of an implicit argument does not involve its syntactic projection.[11] It is clear, though, and here Stanley is right, that we normally use DPs to quantify over less of the domain than the lexical N covers, that is, the domain is restricted. A natural way of codifying this phenomenon is to think of a DP as being associated with a variable that is contextually valued in a way that restricts the lexical domain. So, when one says *Every boy is in the park* in some context *C*, one means and is taken to mean that every boy, in the relevant sense, such as every boy on the school trip you have organized, is in the park. Talking in this way, however, leaves the status of the variable involvement open in the way acknowledged by Partee (1989), that is, whether the variable is a semantic, pragmatic, or syntactic representation. Stanley (2000, 2007), Stanley and Szabó (2000), Martí (2006), and Schaffer (2011), however, contend that quantificational dependence readings can be evidential of the presence of a syntactic free variable; in particular, the claim that general domain restriction on quantificational DPs is realized by a valued covert free variable is supported by the existence of readings where the putative variable is bound.

I shall here consider an argument against this kind of binding consideration due to Recanati (2004), who doesn't so much reject the consideration outright as doubt that it is as compelling as its proponents imagine. I agree. Recanati suggests that the principle in operation here overgenerates, that is, were a quantificational reading reason enough to posit a covert variable, we should find ourselves positing covert variables where there aren't any. In other words, Stanley's (2000) claim that where we have semantic binding, we have syntactic binding, is far too strong a condition, for it obliges us to posit syntactically realized variables for any verb one cares to mention, any verb that can enter into the kind of context exemplified in (17). There are other fundamental problems, too, but space is limited (see Collins, 2007; Neale, 2007; Elbourne, 2008; Pupa and Troseth, 2011). Still, the overgeneration worry is worth discussion, for it has, to my mind, been rejected for inadequate reasons.

So, consider (19):

(19) Whenever Bill cooks mushrooms, Sam eats

Assume we naturally understand this sentence to mean that Sam eats mushrooms on all those occasions when Bill cooks mushrooms. It would now appear, though, that we have to posit a variable as the object of *intransitive eat* in order for it to be bound – an unwelcome result. The problem is that if we are using the quantificational test to determine whether or not a predicate projects a variable, then we appear to be obliged to posit variables where there is no contextual relativity.

Martí (2006), endorsed by Stanley (2007, pp. 226, 244), rejects Recanati's reasoning on the basis that (19) is not essentially quantificational. Consider the following discourse:

(20)A: Whenever Bill cooks mushrooms, Sam eats
B: #No he doesn't; curiously, he eats something else

The supposed intuition marked in (20) is that B's response is anomalous. In distinction, the corresponding discourse about rain is OK:

(21) A: Whenever Bill lights a cigarette, it rains
B: No it doesn't; curiously, it rains somewhere else

If, the reasoning goes, (19) is a case of quantification into the putative object position of *eat*, (20) should be fine, for A's utterance would, indeed, be false, as B reports, should Sam eat something other than mushrooms. That B's response is (supposedly) anomalous signals that the second clause of B's statement does not refute what A said, which shows that the complement of *eat* in A's utterance is not dependent on the content of the fronted adverbial. In (21), there is no corresponding problem, which is meant to indicate that A's utterance in (21), but not in (20), is genuinely quantificational.

I find this argument unconvincing, to say nothing of the fact that were the difference to obtain, it would remain unexplained, since the syntax of the free relatives would remain invariant, presumably, between the two kinds of case.[12] Recanati's point, or at least the point I wish to make, is not that (19) *must* take a bound reading, only that it may do so. Such a possibility suffices to support the overgeneration criticism, for the claim Recanati is challenging is that bound readings mandate as a matter of saturation a variable position into which a prefixed phrase may quantify. A single case is enough to refute the generalization. That general point aside, B's response in (20) is not necessarily deviant. The response, 'No he doesn't,' is elliptical for 'No he doesn't eat' or 'No he doesn't eat mushrooms,' where these completions correspond to what B may intend by his response. On the first construal, B's response is incoherent, for B is simply contradicting herself, saying that A both eats and doesn't eat. On the second construal, B's response is perfectly fine, but is only enabled if *eat* in A's utterance is construed transitively with its object supplied by the prefixed phrase. The situation is the same for (21). The phrase, 'No it doesn't,' is elliptical for either 'No it doesn't rain' or 'No it doesn't rain wherever Bill lights a cigarette.' Again, on the first construal, B's response is incoherent without further ado, for B is being self-contradictory. On the second construal, the response is fine. The cases are therefore symmetrical; the potential for asymmetry arises from differential construal of the ellipsis. Of course, Martí and Stanley assume that the ellipses are filled in differently in the two cases, which generates the differences suggested, but there is no argument for this that I can discern, for both ellipses admit the two fillings I have suggested.[13] Moreover, symmetry is exactly what we would predict on the basis of taking both kinds of construction to feature adjunct free relatives, as they appear to do, which can be the subject of ellipsis or not along with the verb they modify (in distinction to arguments proper, which must be elided). The remaining question is which filling of the ellipsis is favored, if any, and why, but if what I have said so far is correct, then the answers to such questions will not be determined by syntax, which leaves the options open.[14]

All of these considerations concerning weather predicates have been animated by SS and SC constraints: in effect, unless independent syntactic evidence can be found or the relevant readings are necessary (non-optional), a syntactic explanation of the readings available is precluded. No particular theoretical framework need be deployed to arrive at this conclusion.

5 Whither Context?

If all of the above is on the right lines, how should the notion of *context* be understood? The default view, rather than a nihilistic resignation to linguistic chaos, should be that context, as a determining factor in *what is said*, is not a linguistically kosher notion. It pertains to our general ability to attribute content, which is under linguistic constraints, but essentially undetermined by them. Such a view is argued for on its own terms in different ways by linguistic pragmatists of various stripes. One might be tempted by *relativism* of the kind advertised in §2. Tokens of a sentence-type such as *Liquorice is tasty* appear to be true or false relative to an experiencer or a judge. The linguistic type itself, however, is perfectly well formed without an item referring to such an agent, that is, a speaker needn't append *for me*, say, in order to say that liquorice is tasty for them. According to the relativist, for the relevant class of constructions, truth-values can only be assigned relative to the provision of an 'index' or 'circumstance' that is, itself, not a factor of the content of the sentence-type, but includes 'items' to which truth-value is sensitive, such as an experiencer/judge. In its negative aspect, therefore, relativism is akin to the brand of pragmatism I espouse: *what is said* as a truth-evaluable content is not linguistically licensed. Relativism as a positive doctrine, though, would domesticate context, at least in many of its aspects, in a way that is implausible, at least on linguistic grounds.

Correctly, the relativist rejects the putative linguistic license for the indexation of truth-values to (*inter alia*) experiencers or judgers, that is, the narrow linguistic content need not feature variables ranging over relevant agents. It remains unclear to me, though, what the doctrine amounts to, if understood as a thesis about language. It might be, as Lewis (1980) suggested, that the 'shifty' items of the index should correspond to potential linguistic operators. In the spirit of Lewis, if not to the letter of his proposal, Predelli (2005) and MacFarlane (2009) have generalized the basic idea of a 'shifty' index. Assume that there is a *counts as*-operator, much as there are modal (e.g., *possibly*), temporal (e.g., *yesterday*), and precision (e.g., *roughly*/*strictly speaking*) operators. The would-be operator basically resolves how a predication is to be construed relative to the categorization the speaker intends. For example, *x* can *count as* a red pen in one sense but not in another depending on the circumstance. Truth-value of a sentence in context is assigned relative to the value a coordinate of the index takes under the scope of the operator. There is, however, no general covert *counts as*-operator, or at least not one outside of the intentions of a speaker. So, I do not see relativism as an independent position, *if* construed as a general claim concerning the determination of *what is said*. Relativism amounts to another way of spelling out the pragmatist thought that *what is said* is not licensed by linguistic material alone, but by the intentions of the speaker under linguistic constraints.

A related worry pertains to the covertness of the would-be *counts as*-operator, which I take to be necessary, if relativism is to be rolled out for linguistic phenomena generally. It is clear when modal, temporal, and other adverbial operators apply, at least it is clear how we are to construe the relevant word; this is because they are overt, or have overt markers, such as, perhaps, conditional clauses. In these cases, the 'shifty' aspect is directly licensed by the linguistic material. When the putative operator is covert, the construal of the overt material depends upon a myriad of factors concerning the particular speaker and the topic of the claim. On most occasions, I am simply at a loss with moral and aesthetic claims, say, whether the speaker means to be a relativist or not, precisely because the difference is not linguistically marked. In my experience, it really all depends how seriously the person is interested in

the subject at hand. Even with *tasty* and *fun*, it is not obvious whether speakers are making claims about themselves, in a sense, or properties to which others should be sensitive, too. This is *not* a linguistic matter. If we are to imagine a *counts as*-operator as a free-floating device that applies or not depending on the peculiar concerns or intentions of a speaker directed towards some particular subject-matter, then the putative operator is just a notion that labels the phenomena. I should say that I do not mean to doubt that one can build a relativist semantic theory, or that one may construe the *counts as* notion as a meta-theoretical device that fixes a valuation for a non-relativist semantic theory. My concern is simply that such efforts amount to a theorization about *what is said* that renders it as not wholly determined by the linguistic material alone, which amounts to a form of pragmatism.

6 Concluding Remarks

The interface between syntax, semantics, and pragmatics is such an intriguing area because while we know, or think we know, how the broad distinctions should be mapped onto the actual linguistic phenomena, each case, when looked at in detail, offers a great complexity, which should give us pause over the confidence with which we wield the broad distinctions. My intention in the foregoing has been to settle on what I think is the most stable point of the triad, *viz*., syntax, and see context sensitivity is licensed. From that perspective, albeit in the narrow way pursued here, the conclusion seems to be that context sensitivity is not a feature that syntax encodes; rather, syntax simply fails to fix a proposition, leaving the determination of what is said, especially as that notion is sensitive to prevailing factors of the circumstance of utterance, to extra-linguistic factors to determine. This amounts to a version of pragmatism, which follows, not from a direct consideration of the variety of what can be said with a single linguistic type, context willing, but from a modest view of what language alone properly provides to the fixing of content.[15]

Notes

1 As a taster, just consider the open-endedness in the nominal domain of how to interpret genitives and compound nominals. The syntax will determine that *Mary's car*, say, picks out a car that is somehow related to Mary; the determiner phrase (DP) cannot be read as picking out Mary in relation to a car (the Mary who is next to a certain car, say).

2 The notion of *what is said* due to Grice (1989, p. 87) obeys a syntactic constraint, i.e., what is said is expressed by 'the elements of [the sentence], their order, and their syntactic character.' On this view, *what is said* is a thin notion that tracks syntactic-lexical properties. I use the term more ecumenically: *what is said* amounts to the literal truth-evaluable content of an utterance, which, relative to the sentence-type employed by a speaker, may or may not respect Grice's constraint from occasion to occasion. That is to say, Grice's constraint might not issue in a content *p* that is sayable (cp. Bach, 1994). My arguments do not turn on the subtle matter of distinguishing *what is said* from various related notions. It is a term of art to be defined as is useful.

3 See, for example, Richard (2008) and MacFarlane (2014), among many others, for elaboration and defense of relativist positions.

4 The principle initial motivation for a syntactic level of LF was the explanation of scope taking as a semantic property via movement or displacement of the quantifier DP as an instance of a general syntactic rule that admits the movement of any item (under certain conditions). The correctness of this claim and associated hypotheses is irrelevant to our present concerns; it suffices for present

purposes if we minimally assume an independent syntax that constrains possible truth-conditional interpretation.

5 The argument here is set out more fully in Collins (2014).

6 Here I elide great complexity about the significance of the relations in which indexed items must stand if they are to have certain interpretations, but not others.

7 The condition here is not trivial. Consider so-called *depictives*:

(i)a The doctor examined the patient naked
b The policeman arrested the robber drunk

The cases are ambiguous between who is naked/drunk, which appears to contradict the claim in the text concerning adjuncts insofar as the low adjective in these cases can modify the subject. Note, though, that it is the VP being modified. For example, (ia) does not have a reading whereby a doctor, who is naked, examined a patient at some previous time, where both were fully clothed, that is, the doctor, if naked, must have been naked while examining the patient.

8 Perry (1986; 2007, p. 548) is neutral about how the locative position of *rain* is realized, as are Cappelen and Hawthorne (2007) and Hawthorne and Manley (2012, pp. 117–122). Taylor (2001) thinks the position is lexically encoded, but syntactically inert. Korta and Perry (2011, p. 110) endorse Taylor's view, but consider such lexicalization as 'a social phenomenon' contingent on the peculiarities of given speakers rather than a shared lexical competence. Neale commends Taylor's view on a more cognitive construal, without quite endorsing it. Stanley (2000 and 2007) thinks the locative position is marked by a variable in a projected syntactic position (Corazza, 2007, holds a variant of this view), although he remains neutral on precisely how the position is realized syntactically (cf. Stanley, 2007, pp. 248–249). See Collins (2007) for discussion. If one objects to talk of 'standard views,' then it will not affect my arguments if 'Perry *et al.*' substitutes for the offending phrase.

9 Korta and Perry (2011) and Perry (2007) raise the issue not in response to Recanati's weatherman scenario, but Cappelen and Lepore's (2005 and 2007) 'minimalism,' according to which unarticulated constituents are a 'myth.' So, minimalism has it that *It's raining* always expresses some minimal proposition, which is apparently true just if there is rain anywhere at all, even on Venus, say. To accept the intended import of the intergalactic weatherman scenario, however, is not to endorse minimal propositions. All I intend the scenario to show is that location is not saturational because it is optional. It doesn't follow that every grammatical sentence is apt to express a (minimal) proposition, or any proposition at all. Still, the minimalist and the pragmatist are free to exploit the same scenarios for different ends.

10 Stanley is not committed to his putative variables occupying argument positions within the syntactic projection; instead, he appears to think of them as a species of adjunct or even as 'relative clauses' (some kind of free relative, presumably) (Stanley, 2007, pp. 248–249). This makes his position similar to that of Martí (2006) insofar as the variables will be syntactically optional (for discussion, see Collins, 2007). The precise syntactic position of the putative variable will not affect the following arguments.

11 The syntactic status of implicit arguments remains controversial (see Landau, 2013, for recent survey and discussion). What is clear, at any rate, is that implicit arguments in the nominal domain (arguments of so-called relational nouns) appear to be strictly optional, and so not syntactically projected (cf. Adger, 2013).

12 Bourmayan and Recanati (2013) offer related but independent considerations. Although I am sympathetic to their position, our views diverge on details. Bourmayan and Recanati take the basic lexically encoded meaning of intransitive *eat* to be akin to *eat something*, with the object position existentially quantified over. This is problematic, however, given the thematic constraints on complement deletion, which appear to demand a richer construal than *something* for the deletion case. Moreover, by way of situation variables, they take the unbound reading to be 'literal,' and to 'extend' the situation specified in the free relative, with the bound reading being

produced by 'pragmatic modulation' (Bourmayan and Recanati, 2013, p. 134). I share the intuition of the relative availability of the readings, but am happy to think that neither reading is 'basic.' It is plausible that the free adjunct free relative *whenever φ* has a fixed concessive reading, which leaves open whether the construal is bound or not.

13 Of course, the default syntactic position here should be that, in both cases, the ellipsis is filled by copying the bare predicate (*eat* or *rain*), but that, again, would make the cases symmetrical. So, whatever is explaining the asymmetry appears not to be a straightforward syntactic condition on ellipsis.

14 It is plausible, as a matter of pragmatics, that since *eat* does take an object, if it is used intransitively, it is construed indefinitely, which supports the favoring of an intransitive construal of the ellipsis, whereas since *rain* takes no object, the construal of the location is more open to interpretation. None of this, of course, militates against Recanati's overgeneration complaint.

Stanley (2007, pp. 226–227) offers other examples in support of Martí's 'test,' but they are treatable in a similar fashion, I think. A further consideration is offered by Cappelen and Hawthorne (2007), who correctly point out that Martí's discourse test patterns *dance* and other verbs with *rain*: A: Everywhere Jane went, she danced. B: No she didn't, she only danced in a few places. So, on the assumption that *dance* isn't inherently locative, the binding argument overgenerates, treating *rain* and *dance* as both possessing a bindable covert locative variable. If *dance* is *supposed* to pattern with *eat*, then B's response should be anomalous, as if it were contradictory. My take on this case, as with the others, is that the elliptical clause of B's response is ambiguous.

15 My greatest debt is to François Recanati, for the inspiration of his work and many conversations about the issues addressed above, especially during my stay in Paris as a visiting EHESS professor in 2013. I also thank Adam Sennett, Dan Zeman, Emma Borg, Anouch Bourmayan, Kent Bach, Michael Glanzberg, Paul Pietroski, Bob Hale, and especially Alex Miller, for suggestions about both content and style, from which the chapter has benefited greatly.

A Guide to Naturalizing Semantics

BARRY LOEWER

Semantic predicates – *is true, refers, is about, has the truth-conditional content that p* – are applicable both to natural-language expressions and to mental states. For example, both the sentence "The cat is crying" and the belief that the cat is crying are about the cat and possess the truth-conditional content that the cat is crying. It is widely thought that the semantic properties of natural-language expressions are derived from the semantic properties of mental states.[1] According to one version of this view, the sentence "The cat is crying" obtains its truth-conditions from conventions governing its use, especially its being used to express the thought that the cat is crying. These conventions are themselves explained in terms of the beliefs, intentions, and so forth of English speakers.[2] In the following I will assume that some such view is correct and concentrate on the semantic properties of mental states.[3]

In virtue of what do mental states possess *their* semantic properties? What makes it the case that a particular mental state is about the cat and has the truth-conditions that the cat is crying? The answer cannot be the same as for natural-language expressions, since the conventions that ground the latter's semantic properties are explained in terms of the semantic properties of mental states. If there is an answer, that is, if semantic properties are real and are not fundamental, then it must be that they are instantiated in virtue of the instantiation of certain non-semantic properties. Recently a number of philosophers, whom I will call "Semantic Naturalizers," have attempted to answer this question in a way that they take to be compatible with *Naturalism*. Naturalism's central contention is that everything there is, every individual, property, law, causal relation, and so on, is ontologically dependent on natural individuals, properties, and so forth. It is not easy or straightforward to spell out the notion of ontological dependence; but for the purposes of this discussion I will understand it as including the claim that for each instantiation of property M there are instantiations of natural properties and relations, P, P*, …, that together with natural laws and causal relations among the P instantiations *metaphysically* entail M's instantiation. This characterization is intended to capture the idea that M is instantiated *in virtue of* the

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

P instantiations. Or, to put it metaphorically, Naturalism is the thesis that for God to create our world He needed only to have created the naturalistic entities and laws. Everything else follows from these.[4]

Naturalists are seldom explicit concerning exactly which properties are the natural ones. Their working account is that the natural properties are those expressed by predicates appropriately definable in terms of predicates that occur in true theories of the natural sciences.[5] Most contemporary naturalists think that all natural-science properties are identical to, or are exemplified in virtue of the exemplification of, fundamental physical properties. These are the properties that occur in laws of fundamental physics. This version of naturalism is physicalism; all God needed to do to create our world was to create the physical properties and laws and set the physical initial conditions. Whether or not they accept physicalism, Semantic Naturalizers assume that certain modal notions, specifically law, causation, and probability, are naturalistically respectable. Whether these notions can be grounded in contemporary physics (or physics and the other natural sciences), or even whether they may presuppose semantic concepts, is not without controversy. Of course, if these notions presuppose semantic notions then they cannot form the basis for a physicalistic or naturalistic reduction of semantics. At best one would have a metaphysical reduction of semantics.[6] Since this issue is seldom addressed by Semantic Naturalizers, and discussing it would involve us in controversial issues in metaphysics, I will, for the most part, ignore it in the following.

Semantic Naturalism is a *metaphysical* doctrine about the status of semantic properties.[7] Semantic Naturalizers also endorse an *epistemic* thesis that I will call "perspicuous semantic naturalism." It is the view that, at least in some cases, the metaphysical connections between naturalistic and semantic properties are sufficiently systematic and transparent to allow us to see that certain naturalistic conditions are sufficient for certain semantic properties. If Semantic Naturalizers were to find naturalistic conditions that are metaphysically sufficient for semantic properties, and know that they have found such conditions, they would show how semantic naturalism can be true and thus place the semantic within the natural order. This guide reviews recent naturalization proposals and the prospects of the naturalization project.

Although Naturalism in something like the above sense is widely endorsed in contemporary philosophy, there is also an active tradition that is inhospitable to semantic naturalism. Adherents to this tradition think that semantic and natural properties are so radically different from each other as to preclude the former from holding in virtue of the latter. Two lines of thought have been especially influential in this regard. One is that semantic properties are essentially normative. A putative example is that it is constitutive of the concept *cat* that it ought to be applied only to cats. Further, it is claimed, such essential normativity cannot be accounted for in purely naturalistic terms.[8] The second line of thought is that the principles that govern the attribution of semantic predicates lead to the indeterminacy of the semantic attributions even given all possible relevant evidence. For example, given all of a person's verbal dispositions (the supposed totality of relevant evidence), principles of attribution license alternative assignments of truth-conditions and references to that person's sentences and terms. It is a verificationist step, but perhaps one that is not inappropriate in this case, to the conclusion that there is no fact of the matter (within the range of indeterminacy) concerning reference and truth-conditions.[9]

There is not a philosophical consensus concerning how far, if any distance at all, these considerations go in undermining semantic naturalism. However, any adequate account of semantic properties will need to account both for the normativity that content properties

possess and for the determinacy of reference and truth-conditions. We will see these issues coming up in various ways in our survey of naturalistic theories.

But first we should note the consequences if semantic naturalism is false. Those who believe that it is false respond in two ways. One is to claim that there are no semantic properties (or that they are never instantiated). This view, Semantic Eliminativism (Churchland, 1981), thus preserves naturalism at the expense of semantics. The other response is to claim that there are semantic properties but they are metaphysically independent of natural properties. This view, Semantic Dualism (Davidson, 1980, especially pp. 207–224 and 245–260; McDowell, 1994), thus preserves semantics at the expense of naturalism. Neither option is very pretty. Eliminativism strikes some philosophers as self-refuting (Boghossian, 1990) and others (Fodor, 1987) merely as obviously false in light of the success of folk-psychological and cognitive-science explanations that employ semantic concepts.[10] Semantic Dualism seems incompatible with semantic properties playing a genuine causal role in producing behavior. If, as is widely believed, the natural sciences are causally complete, then there seems to be no room for causation (of physical effects) in virtue of properties metaphysically independent of natural properties (Papineau, 1993; Loewer, 1995). So the situation seems to be that while there are reasons to worry that semantic naturalism might be false, there are also reasons to doubt the alternatives. The semantic naturalist will resolve this paradox if he can produce a naturalization of semantic properties. That would be enough to quell doubts concerning semantic naturalism, since we would then know that the gap between the semantic and the natural can be bridged.

The mental states that have been the focus of naturalization proposals are the propositional attitudes: desire, belief, and perception (perceptual belief) (see Chapter 14, PROPOSITIONAL ATTITUDES). There are two parts to naturalizing a particular kind of propositional attitude. First is the specifying of natural facts in virtue of which it is an attitude of that particular type, such as a belief or a desire. Second is the specifying of the natural facts in virtue of which it has its semantic properties, such as its particular truth-conditional content. With regard to the first part, the view held by most semantic naturalizers is that the property of being a particular kind of attitude, such as being a belief, is a *functional* property (Fodor, 1987). Functional properties are higher-level properties instantiated by an individual x in virtue of x (or x's parts) and other entities instantiating lower-level properties that are lawfully or causally related to each other in certain specified ways.

Most semantic naturalizers also think that the property of being a belief (or other propositional attitude) involves an internal mental representation, and that this representation bears the state's semantic properties.[11] On this view, for example, the belief that the cat is crying involves a relation to an internal representation that has the truth-conditional content that the cat is crying. Some semantic naturalizers further propose that mental representations are elements in a *language* of thought, "Mentalese."[12] On this view, complex mental representations are composed of names, predicates, logical particles, and so on, arranged in syntactic structures. Naturalizing the semantics of Mentalese consists in specifying the natural facts in virtue of which simple Mentalese expressions possess their semantic properties, and then showing how the semantic properties of complex expressions are determined by their structure and the semantic properties of their constituents (Field, 1972 and 1978). While not every Semantic Naturalizer buys the language of thought hypothesis, it will often be convenient to presuppose it in what follows.

There are two conceptions of semantic content that have figured in recent discussions of naturalizing content, called "broad content" and "narrow content." "Broad content" refers to

the usual truth-conditional content of intentional mental states. Hilary Putnam (1975) posed thought experiments that have been taken to show that the usual truth-conditional content of certain thoughts fails to supervene on the thinker's intrinsic physical properties. Putnam imagined two people, Oscar and twin-Oscar, who are identical with respect to their intrinsic neurophysiological properties, but who differ in the following ways. Oscar lives on Earth and speaks English. Twin-Oscar lives on a twin-Earth and speaks twin-English. The primary difference between Earth and twin-Earth is that on the latter planet the liquid that fills the oceans, that quenches thirst, and so on is not H_2O but XYZ, a chemical compound indistinguishable from H_2O without chemical analysis. Putnam claims that Oscar's and twin-Oscar's utterances of "water is …" and the thoughts that each expresses with the sentence differ in their truth-conditions. Oscar's thought is true iff H_2O is … and twin-Oscar's thought is true iff XYZ is …. If this is correct, then intentional properties, at least in some cases, do not supervene on intrinsic neurophysiological properties or any properties that supervene on them (such as computational or syntactic properties). This view, *semantic externalism*, is now widely held for thoughts that involve natural-kind concepts like *water*.

"Narrow content" is a term introduced to designate content properties that do supervene on intrinsic neurophysiological properties (Fodor, 1981 and 1987). While Oscar and twin-Oscar's thoughts differ in broad content, they agree in narrow content. Some philosophers (Fodor, 1987) have argued that only narrow-content properties are implicated in intentional causation, and for this reason are required by an intentional science; but there is little agreement concerning exactly how to characterize it, or even whether there are such properties (Stalnaker, 1991). In any case, most of the naturalization proposals concern broad properties, specifically reference and truth-conditional content, so that will be our focus here.

What naturalistic facts are plausible candidates to serve as metaphysically sufficient for the semantic properties of mental representations? Putnam's twin-Earth thought experiments and Kripke's well-known theory of proper names (Kripke, 1972) both suggest that causal relations are involved in determining the references of predicates and names (see Chapter 35, REFERENCE AND NECESSITY, §4). Their considerations seem to carry over to mental representations corresponding to predicates and names. It is plausible that Oscar's mental representation "water" refers to H_2O partly in virtue of the fact that H_2O has caused or is apt to cause Oscar to think water thoughts. And it is also plausible that part of the account of what makes a person's mental representation "Aristotle" refer to Aristotle is that it possesses a causal history that originates with a baptism of Aristotle. Neither Putnam nor Kripke are sympathetic to the naturalization project, but their work is often taken as the starting point for naturalistic proposals. Causation and kindred notions like law, counterfactuals, and probability seem to be the "right stuff," if there is right stuff, out of which to try to build naturalistic accounts of intentionality.[13]

The Crude Causal Theory

I will begin our survey of specific naturalization proposals with the crude causal theory (CCT) for the reference of Mentalese predicates f. No one has ever held the CCT, but it will be useful to describe it and note its most obvious defects, since these are the problems that more sophisticated accounts are designed to solve.

(CCT) It is metaphysically necessary that (if tokens of f are caused by and only by instances of the property F then f refers to F).

The obvious problem with the CCT is that it doesn't allow for the possibility of tokening f or a sentence containing f that is not caused by F. This is called "the problem of error," since if f occurs as part of the perceptual belief that x is an f, then since f is caused by F it follows that the belief is true. But of course, a perceptual belief, such as the belief that x is a cat, may be caused by a small dog, not by a cat. The problem of error is a special case of the disjunction problem. The CCT implies that, whether or not f is a component of a belief, the disjunction of all the causes of f's tokens are the reference of f; so if f is caused by cats, small dogs, utterances of "cat," and so on, then CCT says that f refers to the property of being a cat or a small dog or an utterance of "cat," and so on. Clearly many of the causes of f need not be included within what it refers to. A naturalist successor to the CCT will need to find some way of naturalistically distinguishing the reference constituting causes from the others.

A second problem is that semantic relations are apparently more fine-grained than causal relations. This is the "fine-grainedness problem": f may refer to F and not G even though F and G are metaphysically or nomologically co-instantiated. For example, the properties of being triangular and of being trilateral are apparently distinct, but necessarily co-instantiated. Triangular things cause tokens of f just in case trilateral things do, but a predicate can refer to one property but not the other. Quine (1960) pointed out a pervasive type of property co-instantiation. When and only when the property of being a rabbit is instantiated, so is the property of being an undetached rabbit part. When one of these properties is causally linked to f, so is the other. This makes it quite difficult to see how a causal theory can account for the difference between thinking that 'there goes a rabbit' and thinking 'there goes an undetached rabbit part.'

Dretske's Information-Theoretic Account

Fred Dretske (1981) proposed a close relative of the CCT that identifies the truth-conditions of a belief state with part of the information that the state carries under certain circumstances. The notion of information can be defined this way: state type T carries information of type p iff there is a nomological or counterfactual regularity (perhaps a *ceteris paribus* law) to the effect that if a T occurs p obtains.[14] So, for example, the height of mercury in a thermometer carries information about the ambient temperature. Dretske's idea is to construct the content of beliefs out of the information that they carry under certain circumstances. An initial and crude formulation of the theory is:

(DRET) It is metaphysically necessary that (if B carries the information that p then B has the truth-condition that p).[15]

Versions of both the fine-grainedness and the error problem cause trouble for DRET. If B carries the information p and p implies q then it also carries the information that q. But, of course, one can believe that p without believing that q, even though p implies q. Dretske responds to this problem by identifying the content of a belief with the *maximal* information that it carries under certain circumstances. This is a little progress, but it leaves untouched the problem that if p and q are nomologically or metaphysically co-occurring then any state that carries information that p carries the information that q. So according to

DRET, no belief can have the exact content that there is a rabbit, since any state that carries the information that there is a rabbit also carries the information that there is an undetached rabbit part. Notice that it is of no avail to protest that a given believer might not even have the concept *undetached*, since that doesn't affect the fact that his belief state still carries the information that there is an undetached rabbit part. Dretske's attempts to handle this problem are not successful.[16]

The error problem arises for DRET in this way. According to DRET, the belief that p always carries the information that p, which means that whenever the belief is tokened it is true. Dretske's proposal for solving the error problem is to identify a subclass of the actual tokenings of B as the bearers of the information that constitutes B's truth-conditions. Tokens of B outside of this class have the same truth-conditional content as those within the class, although they may not carry the same information. This permits (but doesn't obligate) the latter tokens to be false. Dretske's initial specification of the class of tokens of the belief state that fix its truth-conditional content is the class of tokens that occur and are reinforced during what he calls "the learning period." His idea is that during this period a type of mental state becomes a reliable indicator of p, and so comes to have the content that p. So Dretske's official account is

(DRET*) It is metaphysically necessary that (if the maximal information carried by B during the learning period is p then any instance of B has the truth-condition p).

DRET* allows for errors, but its naturalistic credentials are questionable. The trouble is that *learning* seems to be a semantic notion. Dretske may think that it is possible to characterize the learning period non-semantically, but he can't just take this for granted. In any case, even if the learning period could be characterized naturalistically, the account is implausible, at least for some beliefs. There are some beliefs that are learned in circumstances in which the information they carry is not the belief's content. For example, when a child learns to token a belief with a content about tigers by seeing pictures of tigers, her belief states carry information about pictures, although their content is about tigers. Dretske's account will end up assigning the wrong truth-conditional contents to these beliefs.[17]

Optimal Conditions Accounts

A different way of specifying a belief's content is in terms of the information it would carry under epistemically optimal conditions (Stampe, 1977; Stalnaker, 1984; Fodor, 1990a; 1990b). The core idea of this approach is that there is a class of beliefs for which there are conditions – the epistemically optimal conditions – under which a person has the belief just in case it is true.

(OPT) It is metaphysically necessary that (if B is a belief of kind K then there are epistemically optimal conditions C_B such that B's truth-condition is p if, were C_B the case, then B would nomologically covary with p).

So, for example, if for subject A there is a belief state B, that under optimal conditions covaries with the presence of a red ball located in front of her, then B's content is that there is a red ball in front of A. In this case appropriate optimal conditions are that A's eyes are open, she is attending to what she sees, the lighting is good, and so on.

OPT allows for errors, since tokens of B that don't occur in epistemically optimal conditions need not be true. It also seems to supply truth-conditions with normative force, at least if epistemic optimality is a normative notion. But, like Dretske's theory, its specification of the meaning constituting conditions is not naturalistic. "Epistemically optimal" is clearly an intentional predicate. It is not at all clear that epistemically optimal conditions can be specified without reference to semantic notions. Different conditions are "optimal" for different beliefs. For example, epistemically optimal conditions for the perceptual belief that there is a red ball in the room include good lighting; but optimal conditions for the belief that there is a firefly in the room are that the lights are off. This example makes it obvious that the optimal conditions for acquiring true beliefs depend on the belief's content. Of course the naturalizer cannot appeal to the content of a belief in characterizing optimal conditions.

Not only are epistemically optimal conditions for a belief sensitive to the belief's content, but for most beliefs, if they possess optimal conditions at all, these conditions involve other beliefs. Whether or not a person's belief state reliably covaries with a state of affairs depends on what other beliefs that person has. For example, a person who fails to believe that fossils are derived from once-living organisms, or who believes that the Earth is 6,000 years old, will not reliably form beliefs about the age of a fossil. If there are optimal conditions for forming beliefs concerning the age of fossils, those conditions will involve having certain beliefs and not having certain other beliefs. To assume that optimal conditions can be characterized naturalistically looks as though it begs the naturalization problem rather than solving it.[18]

Teleological Theories

Teleological theories propose to explain the truth-conditional content of mental states, especially certain desires and beliefs, in terms of their biological functions. A crude teleological theory (CTT) for belief is:

(CTT) It is metaphysically necessary that (if O is an organism and B is one of its belief states and it is B's biological function to carry the information that p then B has the truth-conditions that p).[19]

The concept of a biological function is defined in terms of natural selection (Wright, 1973; Neander, 1991) along the following lines: it is the function of biological system S in members of species s to F iff S was selected by natural selection because it Fs.[20] S was selected by natural selection because it Fs just in case S would not have been present (to the extent it is) among members of s had it not increased fitness (that is, the capacity to produce progeny) in the ancestors of members of s.[21] So CTT says that if B was selected because it carried the information that p, then B has the truth-condition that p.

CTT is naturalistic and allows for error. In fact, it is compatible with almost all tokens of B being false, since all that is required is that B was selected because it carried the information that constitutes its content; and that could be so even if most past and no present tokens of B are true. It also seems to supply truth-conditional content with normativity. Just as a heart ought to pump blood, B ought to be tokened only if it carries the information that p. There are, however, a number of problems with CTT. One is that it directly applies only to beliefs composed out of innate concepts, since only beliefs involving innate concepts could possess a biological function. Perhaps the notion of biological function can be extended

beyond features selected by natural selection; but that remains to be seen. A second, and more worrying problem, is that it either fails to assign determinate contents or assigns contents that are much too thick-grained to be the truth-conditions of beliefs. This problem has been discussed mostly with respect to the belief, or proto-belief, of animals, especially a frog's (the hope being that extension to a human's will come when the bugs are worked out).

Suppose that B is an internal state of a frog that is responsive to stimuli and that controls the frog's snapping behavior. Tokens of the state B in the frog's ancestors generally carried a great deal of information including: that flies are present, that small moving black things are present, that food is present, and so on. Furthermore, since these various conditions were reliably co-instantiated in the environment in which the frog evolved, they are all equally good candidates to be the information that it is the function of B to carry. So CTT implies either that B's content is indeterminate among components of the package or that its content is the whole package of information.

It is not clear whether this is an objection to teleological accounts, since it is not clear what beliefs or desires, if any, frogs have. But it is an objection if teleological accounts are incapable of delivering more fine-grained contents than the one they apparently attribute to the frog. More elaborate theories of content that promise to solve this problem are due to Millikan (1984; 1986; 1989) and Papineau (1993). Both accounts, especially Millikan's, are rather elaborate. Here I will just briefly sketch Papineau's approach.

(PAPB) If D is a desire and B a belief and p is the (minimal?) state of affairs whose obtaining guarantees that actions based on B and D satisfy D then B has the truth-condition p.

If we suppose that the frog desires to catch a fly, and that this desire together with B lead to his snapping, then B's truth-conditional content is the minimal state of affairs that will guarantee that snapping will result in catching a fly. In this case it is a belief with something like the content *if I snap then I will catch a fly*. Of course, PAPB is not naturalistic, since it appeals to the concept of satisfying a desire and that is a semantic concept. Papineau attempts to remedy this by providing a naturalistic account of the contents of desires.

(PAPD) If q is the minimal state of affairs such that it is the biological function of D to operate in concert with beliefs to bring about q then D is the desire that q.

Papineau's idea is that if the desire of type D was selected because it contributed by acting in concert with beliefs to bringing about q, then q is D's content. Let's suppose that the content of A's desire D is that she eats an apple. On a particular occasion, D (together with beliefs) may cause the moving of A's hand, A's eating an apple, A's eating a fruit, and A's being nourished. Papineau suggests that the moving of the hand (to grasp the apple) isn't among D's functions, since there are occasions when D was selected (A's ancestors who possessed D had increased fitness, or D was reinforced in A) even though D didn't cause their hands to move. On the other hand, Papineau supposes that whenever D was selected A ate an apple, ate a fruit, was nourished, and so on. He suggests that the most specific of these features of the behavior which led to D's being selected is D's content; that is, eating an apple.

There are a number of worries that one might have concerning Papineau's account. One is that it applies, at best, only to certain beliefs and desires. PAPB provides contents only to means–ends beliefs (although Papineau suggests how the account can be extended to other beliefs). Many desires could not have been selected for by natural selection, since they are

desires that possess impossible satisfaction conditions, or desires for situations that have never obtained, or have obtained too recently to be selected. It is hard to see how the desire to not have any children (or the desire that no one has any children) could have been selected for on the basis of bringing about its content. Perhaps these objections are not all that damaging if PAPD is intended just as a sufficient condition that applies to a certain class of desires. But then we will need a naturalistic specification of that class of desires. More damaging to PAPD is that possessing the function of bringing about x is not a sufficient condition for D's being the desire to bring about x. Suppose that D is the desire to eat an apple. It is compatible with this that there have been occasions when D led not to apple-eating but to pear-eating (some ancestors of A mistook pears for apples). It is plausible that eating pears (pears being as nutritious as apples) led to increased fitness, in which case D's function is to cause (together with beliefs) eating apples or pears. PAPD yields the result, contrary to our assumption, that D is the desire to eat apples or pears. There seems to be no reason why a desire could not have as its function causing, together with beliefs, some situation that differs from its content. If PAPD is incorrect then PAPB, even if it is correct, is no longer adequate as a naturalization of belief.

It is plausible that the human cognitive system contains subsystems that have the functions of producing states that bring about certain effects, and producing other states that carry certain information (and work in concert with the first kind of state to produce effects). But there is no reason to suppose that these states are individuated exactly in the same way that beliefs and desires are. Truth-conditional content seems much more determinate and fine-grained than anything that teleology is capable of delivering. This is made obvious by considering that there cannot be any selectional advantage for creatures whose beliefs are about rabbits over those whose beliefs are about undetached rabbit parts; yet our contents are so fine-grained as to distinguish these belief states.

Fodor's Asymmetric Dependence Theory

Fodor (1990b) proposed a variant of the causal (or informational) account that is intended to be a naturalization of the reference of a simple Mentalese predicate. It appeals to the idea that the meaning-constituting causes are those which, in a sense to be soon explained, are resilient. It will simplify exposition of his theory to define two technical notions. The law $Q \rightarrow C$ (Qs cause Cs) *asymmetrically depends* on the law $P \rightarrow C$ just in case if Ps didn't cause Cs then Qs would not cause Cs but if Qs didn't cause Cs then Ps would still cause Cs. *C locks onto P* just in case (1) it is a law that Ps cause Cs, (2) there are Qs (= Ps) that cause Cs, and (3) for any $Q \neq P$, if Qs cause Cs then Qs causing Cs asymmetrically depends on Ps causing Cs.[22] If C locks onto P then $P \rightarrow C$ is resilient in that it survives the breaking of $Q \rightarrow C$ for Qs other than P. Fodor's proposal, then, is:

(ADT) It is metaphysically necessary that (if C locks onto P then C refers to P).

Suppose that it is a law that cows cause "Cow"s (or rather the word's Mentalese counterpart), that other things also cause "Cow"s, and that such causal relations asymmetrically depend on the 'cow → "Cow"' law. Then, according to ADT, "Cow" refers to cow. ADT handles the error and disjunction problems this way. Horses on a dark night can cause "Cow"s even though the horses on dark nights are not among the reference-constituting causes of "Cow"; that is, the law that horses on a dark night → "Cow"s depends on the law

that cows → "Cow"s. If a horse caused "Cow" is a constituent of the belief "There is a cow," then the belief is false. Of course, this account of error is correct only if ADT is correct. If ADT is not correct then it may count some erroneous beliefs as true, or some true beliefs as erroneous.

Along with the theory, Fodor provides some commentary that helps to understand it. One point is that the law connecting a property to a predicate that refers to it is a *ceteris paribus* law. That is, it holds only as long as certain unspecified conditions obtain. Presumably this means that only under certain kinds of circumstances do cows actually cause A's mental representation "Cow." Presumably these conditions are that cows are perceptually salient to A, A's perceptual system is in good working order, and so on. A second point involves the dependence relation between causal laws. Sometimes Fodor says that it is a basic relation among laws that cannot be explained in other terms. But sometimes he explains it in terms of counterfactuals; Q → C depends on P → C just in case if P → C had not obtained then neither would Q → C have obtained. Fodor insists that the counterfactual be understood *synchronically*, not *diachronically*. If A learned to recognize cows on the basis of pictures of cows, then it may be that cow → "Cow" depends diachronically on cow-picture → "Cow." That is, it is true that if there hadn't been a causal connection between pictures of cows and A's "Cow"s, there wouldn't be a connection between cows and A's "Cow"s. But Fodor thinks that synchronic dependence goes in the opposite direction. Once A has acquired "Cow" then cow → "Cow" is more resilient than cow-picture → "Cow." A third point is that the account of reference is *atomic*. By this is meant that it is metaphysically possible for A's Mentalese predicate C to lock onto P, even if C bears no inferential or causal relations to any of A's other symbols, or even if A's Mentalese vocabulary contains only the predicate C. Fodor welcomes this surprising feature of his account, since he thinks that there are reasons to hold that inferential or causal relations among thoughts are not constitutive of the thought's semantic properties (Fodor and Lepore, 1992).

There are two questions that need answers to evaluate Fodor's theory. First, is it genuinely naturalistic? And, second, is C locking onto P really a sufficient condition for C's referring to P? Answering these questions is made difficult by the fact that the central notions in Fodor's account – *ceteris paribus* laws and asymmetric dependence between laws – are technical notions that are not clearly defined.

There are two places to worry whether ADT is genuinely naturalistic. First, supposing that it is a law that P → C then it is reasonable to believe that its *ceteris paribus* conditions include having and not having certain other intentional states. We noticed a similar point in our discussion of optimal-conditions theories. Does this make P → C non-naturalistic? Not necessarily. If the fact that P → C is a law is naturalistically reducible, then it too is a naturalistic fact. But do we have any reason other than the belief that semantic naturalism is true to think that P → C is naturalistically reducible?

Second, and more worrying, is whether the dependency relations that Fodor requires are naturalistic. These dependency relations are not themselves the subject of any natural science; so Fodor cannot claim, as the teleosemanticist does, that he is explaining a semantic notion in terms of a scientifically respectable notion, that is, a biological function. Further, it is not obvious that the synchronic counterfactuals that Fodor appeals to when explaining asymmetric dependence have truth-conditions that can be specified non-intentionally. Why is Fodor so certain that the counterfactual (synchronically construed) *if cow → "Cow" were broken then cow-picture → "Cow" would also be broken* is true? Perhaps if the first law were to fail "Cow" would change its reference to cow-picture and so the second law would

still obtain. If so, then while "Cow" refers to 'cow,' ADT would say that it refers to 'cow-picture.'[23] Fodor cannot respond by saying that in understanding asymmetric dependence the counterfactual should be understood as holding the actual reference of "Cow" fixed, since that would be introducing a semantic concept into the explanation of asymmetric dependence. I do not think that these points show that ADT is not naturalistic; but they do show that the burden is on Fodor to argue for the naturalistic credentials of the dependency relation. Fodor sometimes seems tempted to just take the dependency relation to be metaphysically primitive and declare that it is part of the natural order (Fodor, 1991). One could see some irony in calling on such elaborate metaphysical notions to defend scientific naturalism.

Is the fact that C locks onto P sufficient for C to refer to P? It is difficult to answer this question without having a clear characterization of asymmetric dependence. The intrepid philosopher who thinks that she has devised a counter-example to ADT runs the risk of being told by its inventor that she has gotten the dependency relations wrong. There are a number of such putative counter-examples in the literature (Baker, 1991; Boghossian, 1991; Adams and Aizawa, 1994; Gates, 1996) and answers to the counter-examples by Fodor (1991; 1994).[24] Instead of going into the details of these objections I will sketch two general worries about the account.

We attribute propositional attitudes to one another on the basis of folk-psychological generalizations and general information about what people tend to believe, desire, and so forth under certain circumstances. So, for example, if A is a normal human being looking at a cow 100 feet away, then we expect A to believe that there is a cow in front of her. If, in fact, there is not a cow but a cleverly made cardboard cow-façade, then we expect A to at first believe that there is a cow, but that when she moves closer to the cardboard cow and examines it she will cease to believe that there is a cow. Our ability to attribute beliefs, desires, and so on to each other depends, at least in part, on generalizations like these. When testing a theory of intentionality we appeal to such generalizations. We ask whether it is possible for the putative naturalistic sufficient condition for A's believing that p to be satisfied while our folk-psychological generalizations give the result that A doesn't believe that p. The problem I see with ADT is not that there are clear cases in which C locks onto P, but C fails to refer to P; it is rather that, as far as I can see, ADT doesn't engage folk psychology. For all we know, an assignment of beliefs to A employing ADT and an assignment employing the usual folk-psychological principles may diverge radically. I am not arguing that they must or do diverge, but that Fodor has provided no reason to think they don't. The worry isn't an idle one, since it is not at all clear what asymmetric dependence has to do with our folk-psychological principles of belief-attribution. If ADT is to carry conviction we need some account of why it is that the contents it assigns will match those assigned by folk psychology.[25]

The second problem is the familiar one of the inscrutability of reference that seems to bedevil all naturalistic theories. If cow → "Cow"s is a law, then so is undetached-cow-part → "Cow" (and laws involving various other properties metaphysically co-instantiated with cow: Quine, 1960). Neither one of these putative laws asymmetrically depends on the other since they hold in exactly the same possible worlds. So it looks like if a predicate locks onto any property it either locks onto all those properties that are metaphysically co-instantiated, or onto the disjunction of all these properties (Gates, 1996).

One response to the problem is to declare that properties like undetached-cow-part, temporal state of a cow, and so on are not eligible to enter into laws and causal relations. Without a naturalistic justification of this claim the response is another instance of borrowing from

metaphysics to buy naturalism. Fodor, to his credit, has not taken this route, but has suggested an addition to ADT to cope with the problem (Fodor, 1994). He argues that the inferential relations among sentences containing the predicate "Cow" will differ (for a thinker whose Mentalese contains the truth-functional connectives) depending on whether "Cow" refers to cow or to undetached cow part. By adding further conditions on the inferential relations borne by sentences to each other, he proposes to specify sufficient conditions for "Cow" to refer to cow (and no other property). The account is too complex to deal with in detail here. I will just say that, at best, Fodor's proposal excludes some properties from being the references of "Cow," but fails to single out cow as the unique reference.

Causal-Role Semantics

Causal-role (aka "conceptual role" and "inferential role") semantics (CRS) is another approach to naturalizing semantics that deserves mention, albeit only a brief one here. The mention is brief because although causal-role semantics has been in the air for some time (Sellars, 1974; Harman, 1982; Field, 1978; Loar, 1981; Block, 1986) no one has actually proposed a CRS that is naturalistic and assigns specific truth-conditions to mental states or representations. The basic idea of CRS is that the semantic properties of a mental representation are partially constituted by certain causal or inferential relations between that and other mental representations. If only causal relations among mental representations are taken into account, then at best CRS is an account of narrow content. To turn it into an account of broad content, causal relations between mental representations and external items need to be added.

CRS should be distinguished from theories of interpretation like Davidson's (1984) that also ground truth-conditions in causal relations among mental representations (or natural-language representations) and external events. Davidson's theory of radical interpretation places constraints on the contents of a person's propositional attitudes. The most important one is that a correct theory of interpretation should assign mostly true beliefs. But the account is not a naturalization, since the semantic concept *truth* is used in formulating the constraint. (On Davidson's theory, see further Chapter 13, RADICAL INTERPRETATION.)

The immediate difficulty with CRS is that most of the actual causal roles of a Mentalese sentence do not seem necessary for it to possess its truth-conditions. For example, a person's Mentalese sentences "There is a cat" and "There is an animal" might have their usual truth-conditions even though the person has no disposition to infer the latter from the former. Given externalism, CRS cannot adequately specify sufficient conditions for a sentence to possess particular truth-conditions solely in terms of its causal connections to other sentences. It will also need to invoke causal connections with external items. But this brings it back to the problem of specifying exactly which causal connections are content-constituting. CRS has made no distinctive contribution to answering this question naturalistically. The prospects for a naturalized CRS do not look good (Fodor and Lepore, 1992).

CRS seems to fare better as an account of what makes it the case that logical expressions possess their meanings. For example, it is plausible that dispositions to infer S from S#R, and to infer S#R from the pair of premises S and R, are relevant to making it the case that "#" is conjunction. But elaborating this into a naturalistic sufficient condition of "#" to be conjunction is not completely straightforward. The most obvious difficulty is characterizing those causal relations that count as *inferences* without appealing to *truth*.

Conclusion

None of the naturalization proposals currently on offer are successful. We have seen a pattern to their failure. Theories that are clearly naturalistic (such as CCT) fail to account for essential features of semantic properties, especially the possibility of error and the fine-grainedness of content. Where these theories are sufficiently explicit we have seen that they are subject to counter-examples. In attempting to avoid counter-examples, semantic naturalists place restrictions on the reference (or truth-condition) constituting causes or information. But in avoiding counter-examples these accounts bring in, either obviously or surreptitiously, semantic and intentional notions, and so fail to be naturalistic.

Of course, the failure of naturalization proposals to date does not mean that a successful naturalization will not be produced tomorrow. But another possibility, and one that philosophers have recently begun to take seriously (such as McGinn, 1993), is that while semantic naturalism is true, we may not be able to discover naturalistic conditions that we can *know* are sufficient for semantic properties; that is, perspicuous semantic naturalism may be false. It may be that the naturalistic conditions that are sufficient for semantic properties are too complicated or too unsystematic for us to be able to see that they are sufficient. Or, it may be that there is something about the nature of semantic concepts that blocks a clear view of how the properties they express can be instantiated in virtue of the instantiation of natural properties. This position, though it may be correct, is not by itself intellectually satisfying. The least we would like to know is exactly why we cannot know which natural properties are sufficient for semantic properties.[26] As of now, we don't know whether semantic naturalism is true and, if it is true, we don't know whether we can know, of any particular proposed naturalization, that it is correct: though, as we have seen, we can know of some that they are incorrect.[27]

Notes

1 Proponents of this view include Grice (1957), Lewis (1969), and Fodor (1975). For a contrary view see Davidson (1984), who holds that mental and public language semantic properties are interdependent, and that neither is metaphysically prior to the other.

2 The program of accounting for the semantic properties of natural language in terms of those of mental states is identified with Paul Grice (1957) and Stephen Schiffer (1972). A detailed account in terms of conventions can be found in Lewis (1969). See also Chapter 3, INTENTION AND CONVENTION IN THE THEORY OF MEANING.

3 So in the following, "semantic property" means semantic property of an intentional mental state or event.

4 The proposition that Fx is metaphysically entailed by conditions K just in case K together with a characterization of the nature of F logically imply Fx. The best-understood example of this is the realization of a functional property F by lower-level property instantiations. In this case it logically follows from the functional nature of F, the nature of the Ps, and causal relations among the Ps that whenever the Ps are instantiated M is also instantiated.

5 This characterization is vague with respect to what counts as an appropriate definition, as a property, and as the natural sciences. Removing the vagueness raises a number of problems that would take us too far afield to discuss.

6 Hilary Putnam (see, e.g., 1992) has long maintained that causal and nomological concepts are inextricably bound up with intentionality, and for this reason attempting to naturalize semantics is a misconceived project.

7 Although it is a metaphysical doctrine, it is also contingent, since its truth doesn't rule out possible worlds in which some properties are instantiated but not in virtue of the instantiations of natural properties.

8 There are two issues that are often mentioned by those who think that normativity considerations derail semantic naturalism. One is that grasping a concept involves being in a mental state that obligates one to applying the concept only to items in its extension. It is difficult to see how any purely natural state can entail such an obligation (Kripke, 1982; Boghossian, 1989; see also Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING). The other consideration is the claim that the attribution of intentional concepts is constrained by normative principles of rationality and charity (see Chapter 13, RADICAL INTERPRETATION). Davidson (1980; 1984) starts with this claim and tries to fashion it into an argument against the existence of nomic connections between intentional and non-intentional properties. There is little agreement about exactly what Davidson's argument is or even whether its conclusion conflicts with naturalism. Even so, it has been influential, and is often cited or repeated by those skeptical of naturalization (McDowell, 1994).

9 Quine's (1960) arguments for the indeterminacy of translation and for the inscrutability of reference, and Putnam's (1978) so-called model-theoretic argument are instances of this line of thought (see Chapter 26, INDETERMINACY OF TRANSLATION, and Chapter 27, PUTNAM'S MODEL-THEORETIC ARGUMENT AGAINST METAPHYSICAL REALISM).

10 A sophisticated version of eliminativism maintains that robust semantic properties don't exist (or are uninstantiated) but that deflationary semantic predicates can be used to specify reference and truth-conditions. A robust semantic property is a property that may enter into causal explanations and exists independently of our concepts and definitions. In contrast, a deflationary truth predicate, "DT," for a language L is defined by providing a list of the conditions under which the predicate applies; for example, "Snow is white" is DT iff snow is white; "Snow is green" is DT iff snow is green; etc. More generally (p)("p" is DT iff p) where the quantifier is substitutional. An important feature of DT is that, unlike robust truth, it applies only to the language for which it is defined. There is no reason to suppose that items in the extension of a deflationary predicate have anything, in particular causal and explanatory powers, in common. It seems to follow that deflationary semantic notions cannot be employed in causal explanations or play an explanatory role in an intentional cognitive science. The attraction of deflationism (the view that the only instantiated semantic predicates are deflationary ones) is that it both allows us to use semantic predicates for certain purposes (e.g., for infinite conjunction and disjunction) and is compatible with Naturalism. Skepticism concerning deflationism arises from the worry that deflationary truth and reference are too thin to do the work that we want done by semantic concepts. For discussion see Horwich (1990) and Field (1986; 1994).

11 Proponents of this view usually distinguish between explicit and implicit propositional attitudes. Only the former involve relations to mental representations. The latter are dispositions to produce explicit attitudes (Fodor, 1987, ch. 1).

12 Field (1978) and Fodor (1975; 1987) are important sources of this view. Fodor proposes it as an empirical hypothesis that provides the best explanation of certain features of human thought, specifically systematicity and the capacity to engage in logical reasoning.

13 Causation, laws, counterfactuals, and so on are not themselves items mentioned in physics, and it is controversial whether they supervene on physical facts. Even so, Fodor and other naturalizers would consider it a successful naturalization if they could show that intentional properties supervene on these properties. However, Putnam (1992) has complained that notions of law and causation presuppose intentional notions. While this may be true on some accounts of these notions, it is not true on others. For example, on some accounts, probabilities are rational degrees of belief. Obviously, explaining semantic properties of beliefs in terms of degrees of

belief would not contribute to naturalization. On other accounts, probabilities are objective, mind-independent features of the world. In this case there seems to be no danger of circularity, though one may wonder at employing so metaphysical a notion in the cause of naturalism. However, these issues are too complicated to develop here.

14 Dretske (1981) characterizes information in terms of probabilistic relations. There are numerous problems with his account that are avoided by the characterization used here. Also see Loewer (1987).

15 Dretske's formulation characterizes belief functionally as states that guide behavior in certain ways. He doesn't commit himself to a language of thought account of beliefs.

16 This is forcefully argued in Gates (1996).

17 Dretske (1988) suggests a teleological characterization of the state tokens whose information fixes the beliefs content. His basic idea is that those instances of the belief state that produces behavior that is reinforced are the ones whose informational content fixes the belief's semantic content. While this is a naturalistic characterization of the class, it is questionable whether it assigns appropriate contents. It is easy to imagine situations in which a false token of a belief produces behavior that is reinforced. For further discussion of Dretske's theory see Loewer (1987) and McLaughlin (1993).

18 This point is developed in Loewer (1987) and more thoroughly in Boghossian (1991).

19 Some teleological accounts employ a more general characterization of information. S carries the information that p iff $P(p/S \text{ occurs}) > P(p/S \text{ doesn't occur})$.

20 Selection by conditioning (i.e., by reinforcement) also figures in accounts of function devised by some teleosemanticists (Dretske, 1988).

21 For example, the biological function of the heart is to pump blood (not to make a thumping sound) since it is that property of pumping blood (not making a thumping sound) that accounts via natural selection for the presence of hearts. Notice that something may have the function to F even if it doesn't F or seldom Fs. It should be noted that it doesn't follow that every biological system that does something useful has that as its function (or that it has any function). Only those things that a system does that lead to an increase in fitness are its functions. So, for example, it is not obvious that certain cognitive abilities are the product of any function.

22 Fodor sometimes also adds the requirement that the law $P \rightarrow C$ is instantiated. This is supposed to give the result that Oscar's Mentalese "water" refers to H_2O and twinOscar's Mentalese "water" refers to XYZ. However, this addition may not be needed if the dependency relations concerning laws involving Oscar's and twin-Oscar's mental expressions are different.

23 Boghossian (1991) argues that locking on is either not sufficient for reference or is not naturalistic. His argument shows that to get the counterfactuals that underlie the locking-on relation to come out right, the similarity relation relative to which they are evaluated must take into account *semantic similarities*.

24 One of Boghossian's counter-examples to Fodor's theory is particularly persuasive. He imagines a natural kind concept K and laws $X \rightarrow K$ and $Y \rightarrow K$ where X and Y are different substances that are nomologically indistinguishable by us (they behave differently only in black holes). It may then be that neither of these laws asymmetrically depends on the other. Fodor's theory would have the consequence that K refers to the disjunction $X \vee Y$. But surely in the imagined situation K might refer only to X in virtue of the role it plays in physical theory.

25 This point is developed at length in different ways by Carl Gillett and Andrew Milne in dissertations at Rutgers.

26 Boghossian (1990) argues that belief holism (the fact that which situations are apt to cause one to acquire a particular belief depends on one's other beliefs) prevents us from certifying that any naturalistic condition on content-constituting causes or information is correct.

27 I am grateful to Paul Boghossian, Jerry Fodor, Gary Gates, Carl Gillett, and Fritz Warfield for helpful discussion and (not always heeded) advice.

Postscript

PETER SCHULTE

How can mental states be about things in the world? How is it possible that certain mental states are true (or satisfied) under some conditions, and false (or unsatisfied) under others? These questions continue to puzzle philosophers, especially those of a naturalistic bent, since all attempts to explain semantic properties in naturalistic terms face serious difficulties. This has led some theorists to conclude that the whole naturalization program is wrongheaded, but others still adhere to it: while admitting that the task of naturalizing semantic properties is more difficult than naturalists might have initially supposed, they see no reason to be pessimistic about the program as a whole. Hence, the debate about naturalizing semantics – or, more specifically, about naturalizing mental content – continues, and has even intensified in recent years. Since teleological theories are at the center of this debate, I concentrate on them in what follows.

Teleological Theories: Basic Distinctions

It is useful to distinguish between two questions which semantic naturalizers must address (Sterelny, 1995, p. 254). The first question concerns *representational status*: What distinguishes representational states, that is, states with semantic content, from non-representational states? Or, more precisely, in virtue of which natural facts do certain internal states qualify as representational states? Call this the 'status question.' The second question concerns *content determination*: Given that R is a representational state, why does R have the content that p rather than some other content? To put it differently, which are the natural facts that determine the content of R? Call this the 'content question.' Of course, those two questions are intimately related, and many theorists answer them both at once (e.g., Millikan, 1984), but it is important to emphasize that they can be discussed separately.

Traditionally, semantic naturalizers have focused on the content question, and they have continued to do so in recent years. One of the main debates in this area is the debate between proponents of two different teleological approaches to content determination, the *input-* and the *output-oriented* approach. These approaches differ fundamentally in the way they specify the content of descriptive representational states (i.e., 'belief-like' states with a mind–world direction of fit). Consider the descriptive representational state R. According to the input-oriented approach, we have to look 'upstream' at the functions of the mechanisms that generate R, or to R's functional relations to causes or conditions in the world, in order to specify the semantic content of R. One example of an input-oriented account is the "crude teleological theory" (p. 180), which equates R's semantic content with the information that R is supposed to carry (Dretske, 1988). According to the output-oriented approach, on the other hand, R's content is primarily dependent on 'downstream factors' – for example, on the biological function of mechanisms that respond to R, or on R's functional relations to behavior. Papineau's (1993; 1998) teleological theory is a variant of the latter approach, since he proposes that belief content depends on desire content, and that the content of a desire is the most specific state of affairs it is supposed to bring about (p. 181).

The Content Question: Input-Oriented Theories

An attractive new version of the input-oriented approach is Karen Neander's (2013) causal-informational version of teleosemantics. It should be noted that her theory is restricted to a subclass of descriptive representational states – namely, to perceptions. According to Neander, the content of a perceptual state is determined by a certain function of the perceptual mechanism that produces it (i.e., by a function of its 'producer'). More precisely, it is determined by the producer's *response function*: the function to generate R in response to certain environmental conditions p. So Neander's teleological theory is

(NTT) If R is a perceptual state and R's producer has the function of producing R in response to the state of affairs p, then R has the content that p.

Consider again the case of the frog (p. 181), and assume that N is the neural state that (a) is normally produced when there's a small, dark, moving object in the frog's visual field, and (b) normally triggers prey-catching behavior. According to Neander's account, N has the

content that a small, dark, moving object is present, because the frog's visual system has the function of producing N in response to a small, dark, moving object (cf. Neander, 2013, p. 31).[1] *Responding to a small, dark, moving object by producing N* is what, among other things, the frog's visual system has been selected for.

At this point, one might ask: Can't we also ascribe the function of *responding to a nutritious object ('frog food') by producing N* to the frog's visual system? What's more, isn't this description in some sense superior, given that it is only because small, dark, moving objects often contained nutrients that the system was selected for responding to them? This seems to raise the notorious indeterminacy problem all over again (p. 181). However, it should be noted that Neander uses the term 'responding' in a strictly causal sense (Neander, 2013, p. 23). A mechanism can only be selected for responding to some x's being F by producing R if x's being F is *causally relevant* for bringing about the mechanism's production of R. But in the case of the frog, the object's being nutritious is *not* causally relevant for bringing about the visual system's production of N, only the object's being small, dark, and moving is (as can easily be tested by varying the properties independently). Hence, the system can only have been selected for responding to small, dark, moving objects. This is true even though the evolutionary *reason* why the system was selected for doing this consists in the fact that small, dark, moving objects were (often enough) nutritious. (Since Neander also analyzes information in terms of causation, she argues that NTT can be restated as a version of informational teleosemantics. This claim, however, is not essential to her theory.)

Neander's input-oriented account of perceptual content is thus of great interest, since it promises to solve the indeterminacy problem that was fatal to earlier input-oriented theories. Still, there are several objections that can be raised against it. One worry concerns the notion of a response function (Millikan, 2013). Another worry centers on a second problem of indeterminacy, often called the 'distality problem.' This problem becomes apparent when we consider that the frog's N-state normally stands at the end of a long chain of causes – it is caused by a pattern of retinal stimulation, which is caused by a pattern of light waves, which in turn is caused by the presence of a small, dark, moving object. So which of these 'normal causes' constitutes the content of N, according to NTT? Appealing to the visual system's response functions is of no help here: the system has the function f_1 to produce N in response to a certain pattern of retinal stimulation, but also the function f_2 to produce N in response to a certain pattern of light and the function f_3 to produce N in response to a small, dark, moving object (it performs f_3 *by* performing f_2, and f_2 *by* performing f_1). Thus the content of N turns out to be indeterminate. Neander (2013, pp. 33–35) tries to solve this problem by slightly modifying NTT, but it remains to be seen whether this modified account really yields plausible content ascriptions for all relevant cases.

The Content Question: Output-Oriented and Mixed Theories

The most discussed version of the output-oriented approach, and the most discussed version of teleosemantics generally, is Millikan's biosemantics. Millikan first presented her theory in *Language, Thought, and Other Biological Categories* (1984), but has extended and refined it ever since (cf. Millikan, 1989; 2004; 2009). According to Millikan, representations are basically signals passing from a producing mechanism ('producer' or 'sender') to a consuming mechanism ('consumer' or 'receiver'), and descriptive representations are those signals which have to vary systematically with conditions in the environment in order for

the consumer to be able to fulfill its functions. More formally, but still simplified, Millikan's teleological theory can be summarized as follows:

(MTT) R_i is a descriptive representation with the content that p iff (i) R_i belongs to a family of states R_1, …, R_n (the 'R-signals') which stand midway between two cooperating devices, a producer and a consumer, (ii) for the consumer to fulfill its biological functions in a normal way, different R-signals must correspond systematically to different conditions in the external world, and (iii) R_i must correspond to condition p.[2]

To determine the content of a descriptive representation, it is thus crucial to look at the biological functions of the *consumer* of that representation. Since the consumer is located 'downstream' from R, this makes MTT into a version of the output-oriented approach.

The difference between MTT and an input-oriented theory like NTT becomes clearer when we consider what MTT says about the frog case. Here, the relevant family of representations consists entirely of (possible) N-tokens occurring at different times: <N, t_1>, …, <N, t_n>. The producer of these states is the frog's visual system, and their consumer is the prey-catching mechanism – the mechanism responsible for the frog's snapping behavior. The main function of this mechanism is to catch prey, and thus ultimately to provide the organism with nutrients. Since the mechanism is activated by N-states, a covariation between N-states and small (i.e., swallowable) nutritious objects is necessary for the mechanism to fulfill its functions, that is, the representational states < N, t_1>, …, <N, t_n > must correspond to the conditions < small nutritious object present, t_1>, …, <small nutritious object present, t_n>. By contrast, it is irrelevant for the consumer's well-functioning whether the object in front of the frog is dark or moving: the prey-catching mechanism, once activated by N, would fulfill its functions equally well if the small nutritious object were light and stationary. (Of course, it would normally not *get* activated under these conditions, because N would not occur, but from Millikan's output-oriented perspective, this makes no difference to N's content.)

The same point can be put another way. In the evolutionary past, earlier tokens of the prey-catching mechanism have often provided their possessors with objects that were small, dark, and moving. Many of those objects were flies, and most of the flies were nutritious. But according to Millikan, it is only because the prey-catching mechanism provided its possessor with (small) *nutritious* objects that it was evolutionarily successful, so it acquired only the function of catching those objects, not the function of catching small, dark, moving objects or flies. Hence, MTT implies that an N-token occurring at t_1 has the content that there is a small nutritious object present at t_1 (cf. Millikan, 1991, p. 163).

Many objections have been raised against Millikan's proposal. A very influential criticism stems from Neander (1995, pp. 126–127). She argues that MTT, rigorously applied, yields content ascriptions that are *overly specific*. When we take a closer look at the frog case, for example, we find that the fact that really explains the evolutionary success of the prey-catching mechanism is not the fact that earlier tokens of the mechanism provided their possessors (often enough) with small nutritious objects *tout court*, but rather the fact they provided them with small objects that contained enough nutrients to make up for the calories lost in catching and digesting them, and that were, in addition, digestible, free from poison, not contaminated with deadly pathogens, and so on. So the mechanism must have the *function* to provide the organism with objects that have all these properties, and this entails, according to MTT, that all these properties enter into the content of N. To be sure, these consequences are highly implausible.

In recent work, Millikan has replied to Neander's objection by bringing in the functions of representation *producers* and the normal mechanisms by which they perform these functions (Millikan, 2004, pp. 85–86; 2009, p. 404), but it is not entirely clear how this reply is supposed to work in detail and whether it is consistent with Millikan's official output-oriented approach.

Even if the problem of overly specific contents can be avoided, another question remains: Does MTT entail content ascriptions that are *plausible*? Pietroski (1992) construes a case of hypothetical creatures called 'kimus' and argues that the content ascriptions entailed by MTT for this case are in conflict with our pre-theoretic intuitions. Defenders of MTT, however, can simply reject those intuitions as irrelevant (cf. Millikan, 2009, pp. 405–406). Consequently, Neander (2006) pursues a different strategy to attack the plausibility of the content ascriptions entailed by MTT. She considers the states that govern prey-catching behavior in toads, and argues that the content ascribed to these states by MTT (namely that there is a small nutritious object present at t_1, or something along these lines) is implausible from the perspective of mainstream cognitive science, since this content ascription does not fit with standard information-processing explanations of the toad's discriminatory capacities.

Not every teleological account of content can be neatly categorized as a version of either the input-oriented or the output-oriented approach. Some theorists defend mixed theories, holding that 'upstream' *and* 'downstream' factors are important for determining the content of descriptive representations. Carolyn Price (2001, pp. 89–103) and Nicholas Shea (2007, p. 418), for example, add to a broadly Millikanian theory of content the requirement that R must carry *information* about p in order to have the content that p. The addition of an input-requirement of this kind may help to rule out overly specific or otherwise implausible contents: one could argue, for example, that the frog's N-state does not carry information about the absence of pathogens in frog food, so that *not being contaminated with pathogens* cannot enter into N's content. Whether this strategy is successful depends, however, on the details of the theory, and especially on the definition of 'information' that is employed.

The Status Question

So far, the focus of this postscript has been on teleosemantic answers to the content question. But it is important to note that some theories also provide answers to the status question. Most prominently, Millikan's MTT specifies the conditions that are necessary and sufficient for conferring the status of a descriptive representation on R. These conditions include, besides clauses (ii) and (iii) which are also crucial for determining R's precise content, the condition that R must stand midway between two mechanisms, a producer and a consumer, which are designed to cooperate with each other (clause (i)). Thus, at least when it comes to representational status, Millikan's theory is not purely consumer- or output-oriented.[3]

Millikan's answer to the status question has been criticized in several different ways. Some theorists argue that MTT is *too restrictive*, because it requires representations to have cooperating producers and consumers (Sterelny, 1995; Stegmann, 2009). This requirement appears to exclude non-cooperative animal signals like the 'stotting' of gazelles, a behavioral display which (*prima facie*) indicates to approaching predators that they have been recognized, and this may seem problematic (for a reply on Millikan's behalf, see Artiga, 2014). Stegmann (2009) uses similar cases to motivate a purely output-oriented version of teleosemantics, where representational content *and* representational status are determined exclusively by consumer mechanisms and their functions.

Most critics, however, argue that Millikan's status requirements are *too liberal*. Price (2001, pp. 93–96) and Shea (2007, pp. 427–430) describe (hypothetical) organisms whose feeding behavior is triggered by a randomly generated internal state. Since food is abundant in the habitat of these organisms, this way of producing feeding behavior is evolutionarily successful. Millikan seems to be committed to treat the randomly generated internal state of such an organism as a descriptive representation of food, which does not seem adequate. Price and Shea suggest that this defect can be corrected by adding an informational input-requirement to MTT (see above).

But Millikan's status requirements may also be too liberal in a more fundamental way. Burge (2010) argues that Millikan's theory describes many simple systems as representational even though this description yields no explanatory benefits, thus drawing the 'lower border of representation' too low. He even suggests that this defect is shared by all teleological accounts of representation, but this assessment is arguably due to an impoverished conception of the resources available to the teleological approach (Schulte, 2015).

Conclusion

Explaining content in a naturalistic way is not an easy task, and for all we know, it might turn out to be impossible. But the naturalistic proposals that have been formulated and defended in recent years surely deserve serious consideration, and should not be dismissed out of hand. This goes for the theories presented above as well as for those omitted here like, for example, the teleological accounts of Dan Ryder (2004), Mohan Matthen (2005), and Manolo Martínez (2013), or the non-teleological account of Robert Rupert (1999).

Alternatives to Naturalized Semantics have also found new supporters in the past few years. Some adherents of the phenomenal intentionality paradigm accept that semantic content is a primitive feature of mental states, not capable of naturalistic explanation (e.g., Strawson, 2008), and proponents of radical embodied or enactive approaches to cognition deny that there are any contentful mental states at all (e.g., Noë, 2009). But neither of these alternatives has gained wide acceptance among contemporary philosophers. So if one thing is clear, it is that the discussion about Naturalized Semantics will continue for many years to come.[4]

Notes

1 Here and in the following, I'm disregarding a number of empirical details about the case, for example, the fact that the frog's perceptual states also represent the *location* of the object in the visual field.

2 Millikan (1984, pp. 96–97; 2009) spells out the last two conditions in terms of "mapping functions" or "rules of correspondence," but to introduce this terminology here would complicate the matter unnecessarily.

3 For a different take on the status question, see Papineau (2003).

4 I would like to thank Hannah Altehenger, Fabian Hundertmark, Insa Lawler, and Alex Miller for helpful comments.

Inferentialism

JULIEN MURZI AND FLORIAN STEINBERGER[1]

There are two *prima facie* opposing tendencies in philosophical work concerning linguistic meaning and mental content: 'referential' approaches and 'use-theoretic' approaches. According to referential approaches the semantic properties of linguistic expressions and concepts are primarily to be explained in terms of the (broadly) referential relations they bear to (typically) extra-linguistic things (objects, sets thereof, instantiations of properties, etc.). In the case of language, referential relations are understood in terms of mappings from linguistic expressions to the corresponding semantic values in accordance with their semantic types: proper names are mapped onto the appropriate objects, simple predicates might be associated with the properties they designate, and so on. Our use of linguistic expressions is then explained *in terms* of these referential semantic properties: we use the expressions of our language as we do because of their referential properties. A roughly analogous story, it is generally thought, can be told about thought. Use theories of meaning, in contrast, reverse the order of explanation. According to them, it is regularities or rules of use that take center stage. It is these regularities and rules that are accorded explanatory primacy in accounting for meaning and conceptual content, and customary semantic notions such as reference, truth, and satisfaction are explained as a by-product of them. Thus, linguistic practice precedes and shapes semantic theory rather than the other way around.

Plausibly, on a use-theoretic approach, not all aspects of an expression's or a concept's use are equally explanatorily relevant. Accordingly, use theories of meaning differ over which features of an expression's use does most of the explanatory work. Our focus in this chapter is with the particular class of use theories that gives *inference* pride of place in their account of meaning. Use theories of meaning of this sort are commonly known as *inferential role semantics* (IRS) or *inferentialism* for short. IRS is a species of *conceptual role semantics* (CRS). On a broad understanding of it, conceptual role semantics includes "any theory that holds that the content of mental states or symbols is determined by any part

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

of their role or use in thought" (Greenberg and Harman, 2006, p. 295). IRS, as we conceive of it, restricts the semantically relevant features of an expression's conceptual role to the regularities or proprieties of inference (or to some particular subclass of these). The meaning of 'and,' for instance, is often said to be determined by the rules of inference governing it. And to understand 'and,' that is, to know what 'and' means, is to infer according to such rules.

In this chapter, we introduce IRS and some of the challenges it faces. We aim to provide a map of the terrain which offers an overview, but also challenges some of the inferentialist's standard commitments. Our discussion is structured thus. §1 introduces inferentialism and places it into the wider context of contemporary philosophy of language. §2 focuses on what is standardly considered both the most important test case for and the most natural application of IRS: logical inferentialism, the view that the meanings of the logical expressions are fully determined by the basic rules for their correct use, and that to understand a logical expression is to use it in accordance with the appropriate rules. We discuss some of the (alleged) benefits of logical inferentialism, chiefly with regard to the epistemology of logic, and consider a number of objections. §3 introduces and critically examines Robert Brandom's inferentialism about linguistic and conceptual content in general. Finally, in §4 we consider a number of general objections to IRS and consider possible responses on the inferentialist's behalf.

1 Varieties of Inferentialism

Inferentialism is a broad church. In this section, we introduce what we take to be its main varieties, and place them in the wider context of contemporary philosophy of language.

To begin, IRS might be thought to serve as a theory of linguistic meaning. As such, it might be thought of as a theory of the meanings of expressions in a *public* language. Alternatively, it might be taken to be an account of the meanings of expressions in someone's idiolect, or as an account of the contents of symbols in a language of thought, or again it might be thought of as an account of the content of thought.

Some clarification concerning the intended sense of 'thought' is in order. Thoughts, as we will understand them, are the sorts of things that can be grasped or entertained. Thoughts are commonly thought to be composed of concepts displaying something resembling syntactic structure. It follows that thoughts so understood differ from theories that construe propositions as 'unstructured,' for example theories that identify propositions with sets of possible worlds. Thoughts differ also from Russellian propositions, which are composed of the objects, properties, and relations they are about. As Timothy Williamson puts it, "a thought about Vienna contains the concept of Vienna, not Vienna itself" (Williamson, 2006, p. 2). If Fregean accounts of propositions are correct, then thoughts may be propositions. If they are not, thoughts may still express propositions. Though we will not take a stand on these issues here, laying out the options and situating our talk of meaning and conceptual content within them should clarify the discussion to follow.

It is a further question how certain aspects of either of the three aforementioned kinds of meaning – meanings of public language expressions, meanings of idiolectal expressions, and meanings of expressions of a language of thought – relate to conceptual content. Some advocates of IRS maintain that mastery of public linguistic meaning is conceptually prior to conceptual content; that one can only have concepts (or at least concepts of

any degree of sophistication) once one has grasped the meanings of the corresponding linguistic expressions by knowing how to use them (Dummett, 1991; 1993; Sellars, 1956). Others hold the weaker view that linguistic meaning is methodologically prior to conceptual content, or at least that thought and talk must go hand-in-hand in that they must be accounted for in unison (Brandom, 1994; Davidson, 1984; Harman, 1999). Thus, on most forms of IRS, the only way to account for conceptual content is by way of an account of linguistic meaning. The thought, usually, is that concepts can only be attributed to creatures capable of manifesting them, and that linguistic competence is required in order to do so. But that is not to say that all inferentialist accounts abide by this language-first methodology. Loar (1981) and Peacocke (1992) both advance views whereupon inferential roles determine mental content, but where linguistic meaning is parasitic on mental content. Linguistic meaning might then be derived from mental contents according to roughly Gricean lines (Grice, 1957). With this point being noted, in the following we will allow ourselves to slide from (linguistic) meaning talk to (conceptual) content talk.

We have presented referential semantics and use-theoretic semantics (and IRS in particular) as two '*prima facie* opposing' approaches to meaning and conceptual content. Treating them as opposing alternatives is common practice and indeed partisans on either side often proclaim their opposition to the other side. However, as we have also noted, the difference between IRS and referentialism need not necessarily reveal itself at the level of semantic theory; rather, it is a difference *in the order of explanation*: 'Are (broadly) referential relations explanatorily prior to inferential ones or does the order of explanation run in the opposite direction?' And *this* question is in fact a *meta-semantic* question, not a semantic one. The underlying distinction at play here comes to this. *Semantics* concerns itself with the question of which types of semantic values to assign to different categories of expressions, and how, on the basis of these assignments, the semantic values of complex expressions are functionally determined by the semantic values of their constituent expressions. Meta-semantics,[2] in contrast, asks two questions: the *metaphysical* question as to what makes it the case that a given expression has the semantic value it does; and the *epistemological* question as to what a speaker needs to know to count as understanding the expression. Whence our claim that IRS is *not* incompatible with a referential *semantics*. It is incompatible with the meta-semantic thesis that referential relations precede inferential ones in the order of explanation.

A proponent of IRS could thus in principle adhere to a referential *semantic* theory – that is, one that deals in the ordinary semantic concepts of reference, truth, and satisfaction and which assigns the customary (typically) extra-linguistic items as semantic values, while at the same time staying true to the spirit of IRS. IRS might then be interpreted as a meta-semantic thesis – a thesis about what it is in virtue of which an expression has the semantic value it does (what it is in virtue of which a concept has the content it does) or a thesis about what it takes to understand an expression (grasp a concept), or both. IRS, on this meta-semantic interpretation, gives rise to the following two broad theses:

(MD) *Meaning determination*. The meanings of linguistic expressions are determined by their role in inference.

(UND) *Understanding*. To understand a linguistic expression is to know its role in inference.[3]

Thus, a position that takes referential semantics at face value and appeals to IRS as a source for answers to meta-semantic questions is at least conceivable. That being said, given the explanatory priority IRS accords to inferential over referential relations, IRS paves the way for non-standard semantic theories. This may be either because it is thought that IRS constrains semantic theory in such a way as to necessitate the assignment of non-standard semantic values (e.g., assertibility conditions instead of truth-conditions or an epistemically constrained notion of truth in the case of anti-realist theories of meaning like those of Michael Dummett, Crispin Wright, etc.); or it may be because it is felt that substantive relations of reference and truth are not warranted or perhaps not needed once an IRS account of meaning has been offered.[4] Let us call IRS accounts coupled with 'standard' semantic theories *orthodox*, and *unorthodox* otherwise. Moreover, let us call *genuine* those orthodox accounts that take the semantic concepts featured in the semantic theory at face value, and orthodox accounts that are not genuine, *deflationary*.

To bring out some of the characteristic features common to all forms of IRS as well as some of the features by which different of its variants distinguish themselves from one another, it will be helpful to contrast IRS with a theory that *is* straightforwardly incompatible with it. Now, as a species of use-theoretic account, IRS is at odds with any account that takes expressions of a language or concepts to come, as it were, pre-equipped with meanings or contents. Views that run under the banner of informational semantics are a case in point. Roughly, advocates of informational semantics maintain that semantic concepts are to be explained in terms of certain lawlike correlations linking external things or property instantiations to tokenings of corresponding linguistic items or to mental items (Fodor, 1990; Dretske, 2000). The primary mode of semantic explanation thus proceeds by establishing 'direct' language–world mappings. Once the reference and designation relations are established by way of the said reliable correlations between linguistic or mental items and their external causal antecedents, the usual semantic concepts (reference, truth, satisfaction, etc.) are simply explained from the 'bottom up': first, names are associated with their bearers, unary predicates with the properties designated, and so on. In a second step, the theory then specifies compositional rules for determining the semantic values of more complex expressions as a function of their semantically relevant component parts. This atomistic mode of explanation is more congenial to certain types of expressions than it is to others. Paradigmatic cases of linguistic expressions that particularly lend themselves to informational semantic explanation are observational predicates ('square,' 'red') and proper names.

If the prototypical expressions for informational semantical treatment are observational predicates and proper names, the paradigm case for IRS are logical expressions ('and,' 'or,' 'if,' etc.). The semantic values of logical expressions are not readily explained in terms of correlations that may obtain between tokenings of them and external referential relata. Rather, the inferentialist will maintain, the meanings of logical expressions are determined, first and foremost, by their inferential properties which are encapsulated in the rules governing paradigmatic inferences involving them. Taking the case of logical expressions as its model, IRS takes the bulk of the explanatory work to be done by *intra*-linguistic (or language–language) relations (as opposed to by direct language–world links). Moreover, while informational semantics and kindred approaches proceed from the *bottom up* as we have seen, the inferentialist mode of explanation is *top down*: simple declarative sentences are the primary semantic units,

for it is the propositions expressed by them that stand in inferential relations. The meanings of sub-sentential expressions are determined by the contributions these expressions make to the inferential roles the sentences containing them participate in (see Dummett, 1991; Brandom, 1994).

The inferentialist mode of semantic explanation might be thought to apply *locally*, that is, to restricted regions of language such as logical, moral, causal, deontic, epistemic, or theoretical terms; or it might be advanced as a *global* thesis according to which the inferential model of explanation extends to language at large. In order to be able to accommodate expressions that are less straightforwardly explained in inferential terms, global inferentialists will have to include 'language-entry' and 'language-exit' rules (Sellars, 1953) among the relevant 'inferential' connections. That is, uses of expressions like observational predicates will have to be linked to perceptual cues (on the 'entry' side), and they must link up with intentional action (on the 'exit' side). In the absence of any such anchoring of meaning in our experience and interaction with the world, our inferential language game threatens to fail to "latch onto the world"; it could not serve as a means for representing the world. We will be examining local versions of IRS in §2, while global accounts of IRS will occupy us in §3.

The comparison of IRS with informational semantics is telling also in other respects. For one, it may be noted that informational semantics naturally entrains semantic atomism. As Fodor (1990) has stressed, it is possible (at least in principle) on such views that a creature should possess but one concept. Since concept possession depends on being suitably related to the environment, having a concept need not presuppose the possession of others. Things look different when viewed through the prism of IRS, which is incompatible with semantic atomism. The content of a concept is determined by its connections to other suitably inferentially related concepts. Hence, one cannot so much as have a concept without having many concepts.[5] IRS is thus compatible with, but does not mandate, semantic holism – the position that a statement's meaning (and derivatively the meanings of the sub-sentential expressions figuring within it) is determined by the entire network of inferential connections in which it participates. Whether a particular form of IRS endorses holism and how far-reaching that holism is will depend on which types of inferences are taken to be determinative of meaning. If all inferential links – mediate as well as immediate ones – are to taken into account, IRS will amount to an all-out or 'pandemic' holism: the meaning of one statement is fixed by its place in the network of inferential connections linking it to all other statements expressible in the language. By contrast, some versions of IRS treat only certain more restricted subclasses of inferences to be determinative of meaning: analytic inferences or inferences that display a particular counterfactual robustness (Sellars, 1953). Michael Dummett's 'molecularism' is, as the name makes plain, a further attempt at carving out a middle ground between atomism and holism. The molecularist allows for what we might call *semantic clusters*. A semantic cluster is a set of expressions or phrases that are mutually dependent in the sense that the meaning of any member of the set is determined by its inferential links to all the others in the set. Examples are groups of contrary predicates like color words or phrases like 'mother of,' 'father of,' 'child of.' Famously, according to Quine the expressions 'analytic,' 'necessary,' 'synonymous' also form a cluster. What the molecularist opposes is the holist notion that all of these clusters collapse into one all-encompassing master cluster, language as a whole.

Typically, strongly holistic versions of IRS are less apt to answer the epistemological question underlying UND: 'What is it that a speaker must know in order to count as understanding an expression?' For, while all-out holism may be a candidate explanation of how it is, metaphysically speaking, that expressions of a language have the meanings they do, it does not deliver a plausible criterion of linguistic understanding. Transferred to an epistemological key, a strongly holistic version of IRS amounts to the thesis that a speaker must somehow grasp the entirety of the inferential network of links obtaining between all the statements expressible in the language. A claim that seems incredible. Not only would no human speaker of any non-trivial language qualify as understanding any expressions of her language, it also seems deeply unintuitive that my understanding of 'measurable cardinal' (say) should be tied to my appreciation of the correctness of the inference from the proposition that Puck is a cat to the proposition that Puck is an animal. Thus, advocates of IRS *qua* account of linguistic understanding are likely to opt for a non-holistic variant of IRS.[6] The same goes for philosophers who, like Dummett, believe that MD and UND are inseparable, that a theory of meaning is of necessity a theory of what it is a speaker must know in order to understand the expressions of the language. In the following, when we wish to speak of the meaning-determinative or understanding-constituting class of inferential connections in a way that is neutral with respect to the degree of holistic dependence, we speak of the *salient class* of inferences.

Another important choice point is whether IRS is to be interpreted *descriptively* or *normatively*. On a descriptive reading of IRS, the salient class of inferences is constituted by the inferential connections speakers actually make or are disposed to make or accept under various actual and counterfactual circumstances.[7] On a normative reading, MD and UND are understood in terms of the inferential connections we *ought* to be disposed to make or accept. As Daniel Whiting (2006) emphasizes, the normativity in question is not merely consequent upon an expression's having a certain meaning. For instance, that 'cat' means *cat* may have the implication that one ought to apply 'cat' to all and only cats. The case of normative versions of IRS is different. The normativity of the salient class of inferential roles is part and parcel of the meanings they determine: it is because one is in some appropriate sense disposed to recognize the propriety of the inferential connections that one (the community) means what one (it) does by a given expression. Similarly, understanding an expression consists in recognizing the propriety of the relevant set of inferential connections.[8]

This brings us back to another important distinction: the distinction, namely, between individualistic and social (or anti-individualistic) interpretations of IRS. MD, for instance, might be thought of as a thesis about the determination of meanings of a particular speaker's idiolect (at a particular time), or it might be interpreted as a thesis about how the meanings of a public language are fixed. The former thesis is compatible with internalistic conceptions of meaning according to which the determinants of meaning are intrinsic properties of the speaker. Aside from all-out internalism, such views are compatible also with so-called two-factor views. Two-factor views distinguish two aspects of meanings: narrow and broad content. While broad content may be partly determined by the speaker's social or physical environment, narrow content is understood internalistically. Within such a two-factor view, the individualistic reading of an IRS-based thesis about meaning determination might be appealed to as an account of narrow content. In contrast, the anti-individualistic interpretation of IRS is compatible with a social externalism (Burge,

1979; 1986; Putnam, 1981). It is less clear that such views can accommodate twin-earth-type arguments in favor of physical externalism – the view that the meanings of certain expressions, typically proper names and natural kind terms, are in part individuated by their physical environment. For example, in Putnam's classic thought experiment (Putnam, 1975) the meaning-determining inferential roles for 'water' are identical in Oscar's and in Twin Oscar's linguistic communities. All the same, 'water' presumably picks out different substances and hence has different meanings (assuming that meanings determine referents). Some versions of *conceptual* role semantics (incorporated into one-factor views of content) allow for so-called 'long-arm roles,' which 'reach out,' so to speak, to include the speaker's physical environment and her causal interactions within the speaker's conceptual roles (Harman, 1987). Some accept such 'long-arm roles' within IRS. Advocates of IRS who do not – while maintaining that inferential roles determine reference and truth-conditions – will either have to restrict IRS to types of expressions where the physical externalist intuitions have less of a foothold or they will have to dispute those intuitions altogether.

Now, we have said that some proponents of IRS are motivated by MD. But what does it mean to say that inferential roles determine meanings? A fully worked out account of IRS must clarify two things: the relation of determination involved, and the notion of meaning appealed to. Begin with the first of these tasks. On perhaps the most straightforward reading, meanings might simply be identified with inferential roles or rules of inference. Alternatively, meanings might be taken to supervene on inferential roles in the sense that identity of inferential roles guarantees identity of meanings. Or perhaps there are other more sophisticated ways in which inferential roles determine meanings (we will consider one such account in §3).

The second task is not independent of the first. Whether meanings can be identified with inferential roles, for instance, will depend on what meanings are. We consider four uses of 'meaning.' First, 'meaning' may be used to designate the referent or extension of an expression. Second, the meaning of an expression may be equated with the compositional contribution it makes to what is said by a sentence in which it is being used. Third, meanings have sometimes been thought to be the semantic determinants of the referent or extension of an expression. On simple descriptivist accounts, the meaning of a proper name (say) may be a definite description (or cluster of such descriptions). It is in virtue of the description's being satisfied by a particular object that the associated name names its bearer. Fourth, and finally, 'meaning' is often used to designate what it is that a speaker must grasp in order to understand it.

Here is not the place for a comprehensive survey of all of the combinatorial possibilities. Nevertheless, a handful of examples will give the reader an impression of the clarificatory work necessary to fully spell out a version of inferentialism. For instance, inferential roles cannot be identified with meaning in the first sense of 'meaning,' since what we talk about when we talk about Saul Kripke or aardvarks are people and perhaps kinds, properties, or classes of objects, not inferential roles. Similarly, if meaning is understood as the semantic contribution to what is said by a sentence, then if what is said by a sentence is a Russellian proposition or a proposition conceived of as a set of possible worlds, inferential roles, again, cannot be identified with meanings. It is at least conceivable, by contrast, that inferential roles are (or otherwise determine) that which determines reference, or that they are what a speaker needs to master in order to understand an expression having those inferential roles.

Completing the survey would require a similar analysis of other forms of meaning determination.

Enough, then, about IRS's place in the landscape of contemporary approaches in the philosophy of language. The next two sections focus on, respectively, arguably the most important local version of IRS, *logical* inferentialism, and Brandom's global inferentialism.

2 Logical Inferentialism

Though various local brands of IRS have been advanced, logical inferentialism, IRS as it applies to logical vocabulary, deserves special attention. Inferentialist accounts of logical expressions, we noted, seem especially natural. As a result, such accounts are often regarded as a model for IRS in general. As Brandom puts it, typically inferentialists "look to the contents of logical concepts as providing the key to understanding conceptual content generally" (Brandom, 2007, p. 653). We begin by introducing some of logical inferentialism's standard motivations and commitments (§§2.1–2.2). We then discuss a response inspired by Gerhard Gentzen's work to Arthur Prior's famous attempt to undermine the view, and consider a potential corollary of Gentzen's response, *viz.* that logical inferentialism validates a non-classical logic (§§ 2.3–2.4).

2.1 The Only Game in Town?

Inferentialists frequently distinguish two central aspects of the correct use of a sentence: the conditions under which it may be correctly asserted, and the consequences that may be correctly derived from (an assertion of) it. As Dummett puts it:

> crudely expressed, there are always two aspects of the use of a given form of sentence: the conditions under which an utterance of that sentence is appropriate, which include, in the case of an assertoric sentence, what counts as an acceptable ground for asserting it; and the consequences of an utterance of it, which comprise both what the speaker commits himself to by the utterance and the appropriate response on the part of the hearer, including, in the case of assertion, what he is entitled to infer from it if he accepts it. (Dummett, 1973, p. 396)

On their most common interpretation, introduction rules in a natural deduction system (henceforth, I-rules) state the sufficient, and perhaps necessary, conditions for introducing logically complex sentences of the corresponding kind; elimination rules (henceforth, E-rules) tell us what can be legitimately deduced from any such sentence. Logical inferentialism, then, becomes the claim that the meanings of logical expressions are fully determined by their I- and E-rules (corresponding to MD above), and that to understand such expressions is to use them according to such rules (corresponding to UND).[9]

The idea that rules can fix meanings became increasingly popular in the 1930s and 1940s. For logical expressions, the strategy is an especially tempting one. For one thing, one can *prove* that, if $\wedge$ satisfies its I- and E-rules

$$\wedge\text{-}I\frac{A \quad B}{A \wedge B} \qquad \wedge\text{-}E\frac{A \wedge B}{A} \quad \frac{A \wedge B}{B}$$

and if the rules are truth-preserving, then sentences of the form $\ulcorner A \wedge B \urcorner$ must have their standard truth-conditions:

$$(\wedge)\ \ulcorner A \wedge B \urcorner \text{ is true iff } \ulcorner A \urcorner \text{ is true and } \ulcorner B \urcorner \text{ is true.}^{10}$$

For another, a speaker who did not master $\wedge$-I and $\wedge$-E can hardly be credited with an understanding of conjunction. And, conversely, it would seem to be a mistake not to attribute an understanding of conjunction to a speaker who *did* master $\wedge$-I and $\wedge$-E. Indeed, what else could account for one's understanding of logical expressions? As Paul Boghossian puts it:

> It's hard to see what else could constitute meaning conjunction by 'and' except being prepared to use it according to some rules and not others (most plausibly, the standard introduction and elimination rules for 'and'). Accounts that might be thought to have a chance of success with other words – information-theoretic accounts, for example, or explicit definitions, or teleological accounts – don't seem to have any purchase in the case of the logical constants. (Boghossian, 2011, p. 493)

Accordingly, the view that for logical expressions inferentialism is the only game in town, is widely shared.

Boghossian offers a second argument in favor of logical inferentialism, *viz*., that it makes for an elegant account of blind but blameless reasoning – one that seeks to explain how justification (or knowledge) can be transmitted from premises to the conclusion in deductive inference. In a nutshell, any such account is constrained by the failures of simple inferential internalism (SII) and simple inferential externalism (SIE). According to SII, it is required not only that (i) I be justified in believing the premises of a deductive inference and (ii) that the conclusion be justified independently of the premises, but also (iii) that I can know by reflection alone that the premises provide me with good grounds for believing the conclusion. SII amounts to a form of access internalism about deductive inferential justification. Aside from (i) and (ii), SIE requires (iv) that the pattern of inference exemplified be valid (necessarily truth-preserving). Boghossian's proposal is to suggest instead that our inferences are *blind*, because we cannot be expected to satisfy (iii), on pain of starting an infinite regress or else invoking dubious faculties of rational insight. But it is also not enough that our inferences satisfy (iv) since inferences may be reckless and hence blameworthy despite being truth-preserving. So, justification transferral must admit of blind and blameless inferences:

> a deductive pattern of inference *P* may be blamelessly employed, without any reflective appreciation of its epistemic status, just in case inferring according to *P* is a precondition for having one of the concepts ingredient in it. (Boghossian, 2003a, p. 239)

The fact that I take *A* thoughts to be a warrant for believing *B* thoughts is constitutive of my having these thoughts (*A* or *B*) at all. But, then, how can I be epistemically blameworthy for making such an inference? We return to this admittedly controversial argument in §4 below.

The resulting view, then, is an analytic approach to logic – one according to which logical truths are *epistemically analytic* (Boghossian, 1996; 2003b): if *A* expresses a logical truth, then the proposition it expresses can be known on the basis of a grasp of the meaning of the

sentence alone. Whether logical inferentialism is also committed to a *metaphysical* conception of analyticity – one according to which logical truths owe their truth solely to the meanings of the logical expressions (and to the facts) – is more controversial (see, e.g., Russell, 2014; Warren, 2015).

2.2 Harmony

Logical inferentialism is a form of *conventionalism*: certain logical laws, the thought goes, are stipulated to hold or else are somehow extracted from our practice. Thus, Dummett writes:

> Although it is not true of logical laws generally that we are entitled simply to stipulate that they shall be treated as valid, there must be certain laws or systems of laws of which this holds good. Such laws will be 'self-justifying': we are entitled simply to stipulate that they shall be regarded as holding, because by so doing we fix, wholly or partly, the meanings of the logical constants that they govern. (Dummett, 1991, p. 246)

The thought seems to be this: while in the overwhelming majority of cases the question whether we may accept a certain logical law is already settled (it depends on whether the given law can be derived from laws that are already accepted), *basic* laws cannot be justified in this way, on pain of an infinite regress. The question arises, however, whether *any* seemingly basic law can be regarded as determinative of meaning.

An affirmative answer yields disaster, as Arthur Prior's infamous binary connective `tonk` shows (see Prior, 1960):

$$\texttt{tonk-I}\frac{A}{A\ \texttt{tonk}\ B} \qquad \texttt{tonk-E}\frac{A\ \texttt{tonk}\ B}{B}.$$

If the consequence relation is transitive, and at least one theorem can be proved in one's system, then *any* sentence can be proved in one's system. To the best of our knowledge, the first sketch of an inferentialist solution to the problem was given by Gerhard Gentzen in 1934. In a famous passage, Gentzen writes:

> To every logical symbol &, ∨, ∀, ∃, →, ¬, belongs precisely one inference figure which 'introduces' the symbol – as the terminal symbol of a formula – and which 'eliminates' it. The fact that the inference figures &–E and ∨–I each have two forms constitutes a trivial, purely external deviation and is of no interest. The introductions represent, as it were, the 'definitions' of the symbols concerned, and the eliminations are no more, in the final analysis, than the consequences of these definitions. This fact may be expressed as follows: in eliminating a symbol, we may use the formula with whose terminal symbol we are dealing only 'in the sense afforded it by the introduction of that symbol'. (Gentzen, 1934, p. 80)

Gentzen argues that the I-rules of his newly invented calculus of natural deduction 'fix,' or 'define,' the meanings of the expressions they introduce. He also observes that, on this assumption, E-rules cannot be chosen randomly. They must be justified by the corresponding I-rules: they are, in some sense, their 'consequences.' This key thought expresses *in nuce* the idea that I- and E-rules must be, in Dummett's phrase, in *harmony* with each other.

Conversely, if it is thought that E-rules are meaning-constitutive, I-rules cannot be chosen arbitrarily either (see, e.g., Dummett, 1991, p. 215).

This intuitive idea can be spelled out in a number of ways. Dummett (1991, p. 250) and Prawitz (1974, p. 76) define harmony as the possibility of eliminating *maximum formulae* or *local peaks*, that is, formulae that occur both as the conclusion of an I-rule and as the major premise of the corresponding E-rule (see also Prawitz, 1965, p. 34). The following reduction procedure for $\rightarrow$, for instance, shows that any proof of B via $\rightarrow$-I and $\rightarrow$-E can be converted into a proof from the same or fewer assumptions that avoids the unnecessary detour through (the introduction and elimination of) $A \rightarrow B$:

$$\dfrac{\dfrac{\begin{matrix}\Gamma_0,\,[A]^i\\ \Pi_0\\ B\end{matrix}}{A \rightarrow B}\,{\scriptstyle \rightarrow\text{-I},\,i} \qquad \begin{matrix}\Gamma_1\\ \Pi_1\\ A\end{matrix}}{B}\,{\scriptstyle \rightarrow\text{-E}} \quad \rightsquigarrow_r \quad \begin{matrix}\Gamma_1\\ \Pi_1\\ \underbrace{\Gamma_0, A}\\ \Pi_0\\ B\end{matrix}$$

where $\rightsquigarrow_r$ reads 'reduces to.' Dummett (1991, p. 250) calls the availability of such procedures *intrinsic* harmony where, crucially, the reduction reduces the *degree of complexity* of a derivation, that is, the number of occurrences of logical operators. He correctly points out, though, that it only prevents elimination rules from being stronger than the corresponding introductions, as in the case of Prior's `tonk`. It does not rule out the possibility that they be, so to speak, too weak (see Dummett, 1991, p. 287).[11] A way to ensure that E-rules be strong enough is to require that they allow us to *reintroduce* complex sentences, as shown by the following *expansion*:

$$\begin{matrix}\Pi\\ A \wedge B\end{matrix} \quad \rightsquigarrow_e \quad \dfrac{\dfrac{\begin{matrix}\Pi\\ A \wedge B\end{matrix}}{A}\,{\scriptstyle \wedge\text{-E}} \qquad \dfrac{\begin{matrix}\Pi\\ A \wedge B\end{matrix}}{B}\,{\scriptstyle \wedge\text{-E}}}{A \wedge B}\,{\scriptstyle \wedge\text{-I}}$$

where $\rightsquigarrow_e$ reads 'can be expanded into.' This shows that any derivation Π of $A \wedge B$ can be expanded into a longer derivation which makes full use of both $\wedge$-I and $\wedge$-E. Accordingly, a pair of I- and E-rules for a constant \$ can be taken to be harmonious iff there exist both reduction and expansion procedures for \$-I and \$-E. Alternative conceptions of harmony are developed in, for example, Read (2000) and Tennant (1997; 2008). For an overview see Steinberger (2011a). But *why* exactly should I- and E-rules for logical expressions be harmonious?

One motivating thought behind the requirement of harmony is that logic is *innocent*: it shouldn't allow us to prove atomic sentences that we couldn't otherwise prove by first introducing and subsequently eliminating a logic operator (Steinberger, 2009). Yet another motivating thought has it that I-rules determine, in principle, necessary and sufficient conditions for introducing complex sentences. The necessity part of this claim is in effect what Dummett calls the Fundamental Assumption, that "[i]f a statement whose principal operator is one of the logical constants in question can be established at all, it can be established by an argument ending with one of the stipulated I-rules" (Dummett, 1991, p. 252). The Assumption lies at the heart of proof-theoretic accounts of validity (Prawitz, 1985; Dummett, 1991). To see that it justifies a requirement of harmony, let $CG[A]$ be the canonical grounds for a

complex statement A, as specified by its I-rules. Then, we may reason that, by the Fundamental Assumption, B follows from $CG[A]$ if and only if B follows from A itself.[12] In short: it is a consequence of the Fundamental Assumption that complex statements and their grounds, as specified by their I-rules, must have the same set of consequences. That is, I- and E-rules must be in harmony with each other in the following sense: one may infer from a complex statement nothing more, and nothing less, than that which follows from its I-rules.

If harmony is a necessary condition for logicality, then Prior's `tonk` need not worry the logical inferentialist: the `tonk` rules are spectacularly disharmonious, and hence cannot define a *logical* connective.[13] The rules are also *non-conservative*: they allow one to prove sentences in the `tonk`-free language that were not previously provable in the absence of the rule for `tonk` (they allow us to prove any such sentence). And indeed, the first response to Prior's `tonk`, published by Nuel Belnap in 1962, was precisely that admissible rules should yield conservative extensions of the base systems to which they may be added.[14]

The conservativeness requirement is equivalent to the requirement that an admissible logical system S be *separable*, that is, such that every provable sentence or rule in the system has a proof that only involves either structural rules or rules for the logical operators that figure in that sentence or rule. In conjunction with UND, separability makes for an *atomistic* account of one's understanding of the logical vocabulary – one according to which to understand \$ is to know how to use it correctly; the totality of uses of \$ (i.e., the derivations of rules and theorems involving sentences with \$ as their main logical operator) is derivable from the basic rules for \$, and, consequently, one's grasp of \$'s rules is sufficient for knowing \$'s meaning. Thus, on the foregoing view, a speaker could understand $\wedge$ without understanding $\exists$, $\rightarrow$ without understanding $\neg$, and so forth. In so far as our understanding of the logical vocabulary *could* be atomistic, it might be argued that an adequate axiomatization of logic ought to be separable, on pain of ruling out a possible way our understanding actually is.

2.3 *Inferentialism and Logical Revision*

Proof-theoretic constraints such as harmony, conservativeness, and separability rule out Prior's `tonk`. However, it may be argued that they rule out much more. For while the rules of intuitionistic logic are harmonious, standard formalizations of classical logic typically aren't (Dummett, 1991; Prawitz, 1977; Tennant, 1997). For instance, the classical rule of double negation elimination

$$\text{DN}\,\frac{\neg\neg A}{A}$$

is not in harmony with the standard rule of negation introduction:

$$\neg\text{-I}, i\,\frac{\begin{array}{c}[A]^i\\ \vdots\\ \bot\end{array}}{\neg A}.$$

The harmonious rule of negation elimination is the following *intuitionistic* rule:

$$\neg\text{-E}\,\frac{A \quad \neg A}{\bot}.$$

This rule, unlike its classical counterpart, allows us to infer from $\neg A$ precisely what was required to assert $\neg A$: a derivation of $\bot$ from A. But, then, double negation elimination is left, so to speak, in the cold. Similarly, standard axiomatizations of classical logic are not separable. For instance, some uses of $\rightarrow$ such as Peirce's Law, that $((A \rightarrow B) \rightarrow A) \rightarrow A$, are only derivable by means of rules for *both* $\rightarrow$ and $\neg$. Intuitionists such as Dummett, Prawitz, and Tennant have taken this observation to show that classical rules such as double negation elimination are not logical (or that they are in some other sense defective), and that the logical rules we should adopt are those of *intuitionistic logic*, that is, classical logic without the Law of Excluded Middle ($A \vee \neg A$), double negation elimination, and other equivalent rules (or perhaps of a weaker logic still; Tennant, 1987; 1997).

This argument is problematic, however. For while it is true that *standard* axiomatizations of classical logic are not harmonious, a number of non-standard axiomatizations are both harmonious and separable. In particular, classical logic can be shown to be as proof-theoretically as respectable as intuitionistic logic provided rules are given both for asserting and for *denying* complex statements (Rumfitt, 2000; Incurvati and Smith, 2010), where denial is taken to be a primitive speech act distinct from the assertion of a negated sentence (Parsons, 1984; Smiley, 1996). The negation rules for classical negation are then as harmonious as the intuitionistic ones: they allow one to deny $\neg A$ given the assertion of A and *vice versa*, and to deny A given the assertion of $\neg A$ and *vice versa*.[15]

Local forms of inferentialism, beyond logical inferentialism, have recently been developed by a number of authors. For instance, Matthew Chrisman (2010; 2015) and Ralph Wedgwood (2007) develop an inferentialist account of deontic modals, Julian Reiss (2012) offers an inferentialist account of causal claims, Mauricio Suarez (2004) defends an inferential conception of scientific representation. In the next section, we consider the most prominent attempt at elaborating a global inferentialism for language at large.

3 Brandom's Inferentialism

Perhaps the most worked out version of global inferentialism has been put forward by Robert Brandom (1994; 2000; 2008).[16] In this section, we summarize Brandom's account and situate it with respect to the choice points within inferentialism identified in §2. Given the expanse of Brandom's writings and the critical literature it gave rise to, our discussion will inevitably have to omit many noteworthy aspects of Brandom's work and of the responses to it.

Brandom's account, like any inferentialist account, is use-theoretic or, in his preferred vocabulary, pragmatic. Semantics, in Brandom's slogan, is 'answerable to pragmatics' (Brandom, 1994, p. 83). His account's point of departure is the *doings* of linguistically endowed creatures, in particular their practices of asserting and inferring which, according to him, 'come as a package' (Weiss and Wanderer, 2010 p. 313). It is through the speech act of assertion that we advance claims which, in turn, are expressed by declarative sentences. And it is the contents of these assertions (expressed by declarative sentences) that are susceptible of standing in inferential relations. It is for this reason that declarative sentences are taken to be the primary unit of significance and so enjoy a privileged semantic standing (Brandom, 1994, p. 79).

Aside from being a use theory of meaning, Brandom's theory may further be classified as an assertibility theory of meaning: the meanings of declarative sentences are to be

explained in terms of the conditions under which an assertion is appropriate or correct. However, Brandom's approach differs in a number of significant ways from other types of assertibility theories.

Brandom follows Dummett's lead in seeking to extend to the whole of language Gentzen's bipartite model of the meanings of logical expressions in terms of I-rules and E-rules (see §2). On the proposed picture, the meaning of a sentence (or of a thought) can be characterized in terms of the two aspects of its assertoric use: the 'set of sufficient conditions' that would warrant its assertion and the 'set of necessary consequences' (Brandom, 2000, p. 63) of doing so (as well as, we will see, the set of claims incompatible with it).

Crucially, the inputs for and the outputs of assertions are construed inferentially. That is, the meaning of a sentence is to be explained via its inferential antecedents and consequences. The meanings of sub-sentential expressions, though unfit in and of themselves to act as relata of inferential connections, are then to be accounted for in terms of the systematic contributions they make to the assertibility conditions of the sentences of which they are constituents. Their semantic contributions are accounted for in terms of their substitutional behavior (Brandom, 1994, ch. 6). Where Brandom departs from Dummett is in the deflationary nature of his account. Traditional semantic notions of reference and truth are explained in broadly deflationist terms, as having an 'expressive' role – they enable us to render explicit certain intentional and anaphoric features of our practice which otherwise remain implicit within them (Brandom, 1994, ch. 5).[17]

As we noted in §2, certain expressions appear to lend themselves more readily to inferentialist treatment than others. However, since Brandom's account lays claim to global applicability, it must be capable also to account for observational predicates like 'red,' for instance. According to Brandom, even the possession of a color concept like *red* requires more than merely an ability to respond differentially to red things. Parrots, barometers, and thermometers all respond differentially to certain stimuli, yet they cannot be credited with the corresponding concepts. Full conceptual competence presupposes an appreciation of the inferential connections from and to thoughts containing the concept in question, for example, the inference from 'this is crimson' to 'this is red,' or from 'this is red' to 'this is colored.'

What confers meaning on a sentence is that it may be correctly inferred from certain sentences, and that other sentences may be inferred from it. This presupposes an appreciation on the part of the speaker that the sentence may act as a premise and as a conclusion in arguments.[18] In Brandom's oft-cited Sellarsian slogan, the meaning-determinative linguistic and conceptual practices of asserting and inferring are to be conceived of as taking place within the 'game of giving and asking for reasons.' His aim is to explain how our practices of asserting, challenging, defending, and retracting assertions by exploiting the inferential connections within which the asserted contents stand, are able to confer meanings on the linguistic vehicles by which these linguistic acts are performed.

Crucially, the meaning-constitutive inferential patterns are not *formal* inferences (i.e., deductive relations that are truth-preserving in virtue of the logical forms of the claims), but rather *material* ones including analytic inferences like 'Philadelphia is south of New York City; therefore, New York City is north of Philadelphia' as well as defeasible *a posteriori* ones like 'this substance burns in a white flame; so, this substance is magnesium.' It is these material inferential relations (not formal ones) that we rely upon in justifying, challenging, and defending our assertions, and it is therefore they which constitute inferential roles of sentences.[19] The supposed primacy of formal inference is taken to be an artifact of the

referentialist order of explanation: sub-sentential expressions are thought to have semantic values in virtue of the referential relations they stand in. These semantic values compositionally determine the truth-values of sentences. And these, together with the logical forms of the sentences, go on to determine the formal logical consequences of those sentences. On Brandom's account, by contrast, it is material inference that takes center stage. Indeed, logical concepts are inessential to (non-logical) conceptual practices. The role of logical vocabulary, as that of semantic vocabulary, is *expressive*, according to Brandom. It is in virtue of such expressive vocabulary that we are able to subject our concepts to critical scrutiny, laying bare the commitments we incur by virtue of operating with those concepts. However, it is not directly determinative of meaning.[20]

An important feature of Brandom's inferentialism, we said, was the bipartite structure of its analysis of assertibility conditions, which it inherits from Dummett. Like Dummett, Brandom rejects assertibility theories that focus on the grounds of assertion to the exclusion of the consequences of assertion. Such one-sided accounts, he claims, are unable to discriminate the meanings of 'I will write a book about Hegel' and 'I foresee that I will write a book about Hegel.' For while the circumstances warranting the assertion of either sentence are the same, the consequences of doing so differ Brandom (2000, p. 65). One-sided accounts, according to him, are unable to account for that difference.

Also, much like Dummett, Brandom's inferentialism is a broadly social and normative inferentialism. The relevant meaning-determining inferential roles are the ones that govern not the expressions of a particular idiolect but those of a public language. What is more, inferential roles, for Brandom, are not to be construed merely as *regularities* within a social inferential practice, but rather as *proprieties* and so normatively. Where Brandom's assertibility theory goes beyond Dummett's is in that he aims to offer an analysis of the 'normative fine structure' of the grounds and the consequences of asserting in terms of the normative categories of *commitment* and of *entitlement*.

Start with commitment. Asserting is a way of expressing one's endorsement of a proposition. But for such an endorsement to have the distinctive force of an assertion, it must be subject to the norm that assertions entail commitments to the material implications of the asserted contents. A speech act not accompanied by such a commitment would not qualify as an assertion. For instance, in asserting that this is red, I commit myself to the claim that this is colored. Commitment thus has the deontic force of obligation: having asserted that this is red, I ought also to endorse what follows from the content of my assertion, for example, that this is colored.

The second category of entitlement must be understood against the backdrop of Brandom's rationalism about language. The practice of asserting, for him, is essentially bound up with our practice of exchanging reasons. Upon advancing a claim by asserting it, I may appropriately be challenged by you. I meet your challenge by demonstrating my entitlement to the claim, for instance by pointing to a further claim to which I am already entitled and from which the claim I advance may be correctly inferred. For example, I can demonstrate my entitlement to the claim that this is red provided that I am entitled to the claim that this is scarlet. The reason my entitlement carries over from an assertion of the latter sentence to an assertion of the former, is because the sentences express contents that stand in an entitlement-preserving inferential relation. While commitments corresponded to the 'deontic status' of obligations, we can now see that entitlements correspond to permissions.

The deontic modalities (like other modalities) of obligation and permission are customarily taken to be duals of one another as witnessed by their interdefinability with the help of

formal negation (e.g., it is obligatory that *p* just in case not-*p* is not permissible and vice versa). Given his conception of logical vocabulary as having an expressive and hence auxiliary role, Brandom does not wish to appeal to the formal concept of negation at this explanatorily fundamental level. Nevertheless, commitments and entitlements interact in important ways. In particular, Brandom defines a notion of incompatibility or material negation in terms of them: two propositions are incompatible with one another just in case commitment to one precludes entitlement to the other.

Aside from being able to give a more refined account of the central notion of inferential role, Brandom claims that the three additions to his conceptual tool belt – commitment, entitlement, and incompatibility – enable him to deal with a problem that has long bedeviled assertibility theories of meaning. To see what the trouble is note that assertions can be said to be correct in two ways. An assertion can be said to be correct *by the lights* of the agent or of the agent's linguistic community if it is warranted by the relevant standards (e.g., 'Was the evidence properly taken into account?' 'Were the inferences made sound ones?' and so on). But of course even though the individual may be subjectively correct and hence blameless, he may still be wrong. So there is a second, objective sense in which an assertion's correctness may be appraised. In this sense an assertion is correct just in case it is true, that is, just in case it tells it how it is. Traditionally, Brandom claims, assertibility theories have struggled to account for objective correctness in this sense.

Oftentimes the assertibility theorists resorted to certain types of idealizations in order to narrow the gap between the two types of normative appraisals by defining objective correctness as subjective correctness under certain ideal conditions (perfect evidence, at the end of inquiry, etc.). Brandom believes that idealizing maneuvres of this kind are doomed to failure. For a typical problem case consider Brandom's example:

(1) The swatch is red.
(2) The claim that the swatch is red is now assertible by me.

Although the second sentence merely seems to make explicit what according to the assertibility theorist is implicit in the act of asserting the first sentence, the two sentences intuitively differ in content. The two sentences, though assertible in the same circumstances, differ in their truth-conditions. However, Brandom believes that his account delivers the means necessary to capture the difference in semantic content without abandoning the assertability. For the two sentences to have the same content, they would have to rule out the same claims; they would have to be, in Brandom's vocabulary, 'incompatibility-equivalent' (Brandom, 2000, p. 199). But this is not the case. For instance, (1) is compatible with it being the case that rational beings have never evolved, whereas (2) is not.[21]

Needless to say, Brandom's grand project has faced a great number of criticisms.[22] Here we will single out merely one central strand of criticisms because of its relevance to other inferentialist enterprises: Brandom's holism.[23] In §2, we noted that if inferentialism is to play the part of a meta-semantic account – a theory of MD, of UND, or both – it must explain which types of inferences have the relevant meta-semantic relevance; that is, which inferences are meaning-determinative or which ones are understanding-constitutive. Brandom, we have said, endorses the controversial thesis that *all* inferential connections to which the sentence contributes are relevant. We have already noted some of the intuitive difficulties faced by Brandom's view *qua* theory of understanding. In the following passage Brandom

himself stresses in particular the difficulty of accounting, on a holistic account, for the 'possibility of communication or of interpersonal understanding':

> If the inferential significance of a claim depends on what else one is committed to, then any difference between the collateral commitments of speaker and audience can mean that a remark has a different significance in the one's mouth than it does in the other's ear. How is it then possible to make sense of the idea that they understand one another, so as to be able to agree or disagree? If the contents expressed by sentences must be individuated as finely as the theories they are embedded in, the intelligibility of communication across theories – the very notion of conveying information – is threatened. […] If, because of his very different collateral commitments, Rutherford meant something quite different by 'electron' than I do, it seems I can't disagree with him about whether electrons have fixed positions and orbits, since I can't either say or think anything with the content he would have expressed by saying "electrons orbit the nucleus." How, then, are we to understand so much as the possibility of cognitive progress in science? (Brandom, 2007, p. 666)

How, in the light of this is a holistic account of understanding and communication to get off the ground? A natural answer, it might be thought, is to maintain that Rutherford's and Brandom's use of 'electron' overlap sufficiently to ensure communication; that their uses of the term are sufficiently similar. However, Fodor and Lepore (2001) and others have argued that such appeals to similarity will not do. The reason, according to them, is that any appeal to similarity in use would appeal to related expressions. For instance, it is of no help to point to the fact that both Brandom and Rutherford may agree that electrons are negatively charged, because their different theoretical commitments lead them to assign different meanings to 'charge' (see Fodor and Lepore, 2001). However, Brandom takes this conclusion to be too hasty. While it may be that many of the inferential roles the two associate with the expression differ in myriad ways, many of the non-inferential circumstances under which both would apply the term are the same, or at least sufficiently similar:

> Thus Rutherford and I are both disposed to respond to a bolt of lightning by applying the term 'electron', and to respond to applying the expression 'high voltage, high amperage electron flow' to a bare piece of metal by avoiding contact with it. These language entry and language exit moves, no less than the language-language ones, also give us something important in common, even when described at a so-far-subsemantic level, that is, in a nonsemantic vocabulary. I do not see why the structures so-described do not underwrite a perfectly intelligible notion of partially shared, or merely similar inferential roles. (Brandom, 2007, p. 666)[24]

Moreover, Brandom dismisses the notion that understanding should be understood on the 'Lockean' model according to which my understanding you consists in your idea being transferred or reproduced in my mind. Instead, we should understand 'understanding' in accordance with Brandom's picture of the normative practices that are constitutive of meanings in the first place. One's advancing a sentence assertorically should be understood against the background of social 'scorekeeping' practices in which my interlocutors track my and others' commitments and entitlements as a result of my assertion (see Brandom, 1994, pp. 180ff.). These scorekeeping practices represent Brandom's account of how it is that content-conferring norms are socially instituted. They are thus to be understood as an

attempt at a reductive (though non-naturalistic) account of content. Contents (and intentionality with them) are to be understood in terms of the normative practices by which we monitor and assess our rational discourses of asserting, challenging, justifying, and retracting. "The capacity to understand each other," on this picture, "is the practical ability to navigate across the gulf between doxastic perspectives created by the effect of differing collateral commitments on the inferential significance of one noise in the mouth that utters it and the ear that hears it" (Brandom, 1994, p. 667). The trouble with this reductive view, however, is that it seems hard to see how explanatorily basic normative practices can be described without already making use of intentional vocabulary (Fodor and Lepore, 2010; Rosen, 1997).

Rather than further dwelling on objections specifically leveled at Brandom, we now turn to a number of more general objections to inferentialism.

4 Objections and Replies

Objections to IRS are legion.[25] For reasons of space, we focus on two main lines of criticism: a general worry about IRS *qua* unorthodox semantics, and Timothy Williamson's recent sustained attack to UND, understood as the claim that to understand an expression is to be disposed to make and accept basic inferences featuring it. We begin with the former.

The thought that the content of a sentence in context is given by, perhaps among other things, its truth-conditions – truth-conditional semantics, for short – lies at the heart of much of contemporary linguistic semantics and philosophy of language. As Williamson observes, "this simple idea has been basic to the massive development of mainstream formal semantics over recent decades, in both linguistics and philosophy of language, for natural and artificial languages" (Williamson, 2010).[26] However, Williamson argues, this simple and fruitful idea is incompatible with IRS. He writes:

> If you want an explicit theory of how some particular linguistic construction contributes to the meanings of sentences in which it occurs, the inferentialist is unlikely to have one. Better try the referentialist. (Williamson, 2010, p. 23)[27]

The thought seems to be this. Given the empirical success of contemporary truth-conditional semantics, it would be a mistake to abandon it on philosophical grounds, in favor of an untested, and mostly under-developed, alternative inferentialist semantic theory, which, at least in its present state, seems too crude to rigorously account even for fairly commonplace semantic phenomena. However, our discussion in §1 shows that this objection may be off target.

The objection conflates the levels of semantics and meta-semantics. The proponent of IRS can in principle be impressed with the advances of referential semantic theories and indeed endorse them, while maintaining that meta-semantic questions – MD and UND – call, in whole or in part, for an inferentialist treatment. In §2, we called inferentialists of this type orthodox. The inferentialist at the level of meta-semantics then faces the further question as to how the referentialist's semantic values are to interpreted: Are they to be taken at face value metaphysically or not? That is, in our terminology, is the inferentialist a *genuine* (orthodox) inferentialist or a *deflationary* one? As for MD, several authors (see, e.g., Peacocke, 1992; Hodes, 2004; MacFarlane, 2005) have maintained that an inferentialist

account of MD as applied to logical expressions is compatible with truth-conditional semantics for them – indeed, in suitable presentations of classical logic, inference rules *fix* the semantic interpretation of the logical vocabulary (e.g., Smiley, 1996; Rumfitt, 2000). The same is true for other expressions, such as deontic modals (see, e.g., Wedgwood, 2007; Chrisman, 2010) and indeed perhaps for the whole of language. Among these authors, some might advocate genuine variants (e.g., Wedgwood, 2007) others deflationary variants of deflationism (e.g., Brandom, 1994; 2000).

Williamson, however, remains skeptical. He writes:

> Since inferential relations do not fix truth and reference, meaning has not been adequately tied to the language-independent world. (Williamson, 2010, p. 23)

But Williamson simply *presupposes* the falsity of meta-semantic interpretations of MD. Pending an argument for this presupposition, it seems fair to conclude that the general worry against inferentialism has little to go on.

Let us turn, then, to the second general line of criticism. In a number of publications, Williamson has launched a sustained attack afflicting, according to him, various "programs which go under titles such as 'conceptual role semantics', 'inferentialism' and 'use theories of meaning'" (Williamson, 2006, p. 6, n. 5). Once again it is important to situate Williamson's objections within the map of inferentialist positions laid out in §2. The target of Williamson's criticism is the inferentialist's claim to be able to account for UND; it in no way concerns MD. What is more, Williamson's criticisms presuppose that understanding a sentence, for the inferentialist, is constituted by a grasp of certain epistemically analytic inferential relations. For instance, as we have seen, it may be a necessary condition in order to count as understanding 'and' that one appropriately recognizes the correctness of the inferential relation from $\ulcorner A$ and $B \urcorner$ to A and to B. The assumption, here, is that there must be some salient subset of the inferential relations an expression enters into that is constitutive of understanding it. Hence, on Williamson's picture, the inferentialist is committed to a version of epistemic analyticity in the sense of Boghossian (1996; 2003b). It is a consequence of this that, necessarily, someone who understands a given sentence, appropriately accepts certain inferences from and to that sentence. Williamson's objection to inferentialist theories of understanding do not, therefore, tell against theories of this type that do not rely on epistemic analyticity in this way. It is at least worth noting that not all inferentialist accounts of understanding are committed to epistemic analyticity in this way; our discussion of Brandom's holism in §3 is a case in point.

What, then, does Williamson's objection amount to? For simplicity, we summarize the objection as it is directed against any form of analyticity-based account of understanding; inferentialism amounts to a special case. His take-home message is this: understanding is an elastic notion – it cannot be adequately captured by any account that ties understanding to necessary conditions on the assent/dissent patterns of individual speakers or their acceptance of certain inferential relations. Consider the sentence

(`Vixen`) Every vixen is a female fox.

According to UND, necessarily, whoever understands `Vixen` assents to it. It is constitutive of one's understanding of '`Vixen`' that under suitable conditions (e.g., provided one

understands the remaining words occurring in the sentence), one assents to `Vixen`. Call a theory of understanding of this general form a *criterial* theory of understanding. Williamson provides a recipe for generating counter-examples to any such theory.

Suppose e is an expression, m its meaning. According to a criterial account of understanding, there must be a sentence or pattern of inference $C(e)$ such that a speaker's assent to it or appropriate recognition of it is necessary for her to count as understanding e. Williamson claims to have a general recipe for cooking up counter-examples to any such $C(e)$, for any e. Namely, we can imagine an expert on m who, on (possibly erroneous) theoretical grounds, rejects $C(e)$. By the criterialist's standards our expert does not understand e. But surely, by any ordinary standards, she *does* understand e – she is an expert, after all.

In order to get a better feel for the foregoing schematic objection, let us consider one of its instances. Suppose, as seems *prima facie* reasonable from the inferentialist's point of view, that an appropriate appreciation of *modus ponens* (MP) is constitutive of understanding 'if.' As for any case, Williamson believes a counter-example can be concocted also for this case. That is, a counter-example in which an expert whose semantic competence cannot reasonably be questioned rejects the criterial pattern of inference or sentence. Indeed, no concocting is even needed in this case, Williamson thinks: in Vann McGee we already have a ready-made, real-life example of someone who is undeniably an expert about conditionals but nevertheless denies the validity of MP. His denial is founded on a number well-known putative counter-examples involving nested conditionals (see, e.g., McGee, 1985, p. 462).

For present purposes, it does not matter if McGee is right – we may even suppose that his example is fallacious, and that 'if' in English satisfies MP after all.[28] What matters is that, his erroneous views about MP notwithstanding, McGee surely understands 'if.' All the same, according to UND it seems we must say that he does not. So UND must be false, or so Williamson argues.

Williamson constructs structurally similar cases for the material conditional, for 'for all' and for 'and' (Williamson, 2003; 2007; 2011; 2012). His conclusion is that agreement in understanding doesn't require perfect agreement in use. All that is needed for a speaker to understand an expression of e is that she fully participate in the social practice of using e within her linguistic community. He writes:

> Each individual uses words as words of a public language; their meanings are constitutively determined not individually but socially, through the spectrum of linguistic activity across the community as a whole. The social determination of meaning requires nothing like an exact match in use between different individuals; it requires only enough connection in use between them to form a social practice. Full participation in that practice constitutes full understanding. (Williamson, 2007, p. 91)

Williamson's argument, then, is premised on what is sometimes referred to as *social externalism* (Burge, 1979; 1986): linguistic understanding is always understanding of a public language whose meanings are typically non-individualistically individuated. On the assumption that the community-wide use of 'if' largely conforms to MP, it is this assumption that allows Williamson to maintain that McGee's understanding of 'if' is unaffected by his rejection of certain instances of the rule. How can the inferentialist respond?

We begin with two observations about the *scope* of the argument. To begin, the objection does not target IRS directly. Rather, it aims at undermining a certain account of

understanding that can be – and typically is – associated with it. What is more, the argument does not apply to holistic versions of IRS, such as Brandom's. According to Brandom's inferentialism, one's understanding of an expression *e* is constituted by one's grasp of the entire network of inferential connections in which *e* participates. But, since such a totality typically slightly varies from speaker to speaker, it may be argued that it is to be *expected*, on Brandom's view, that different speakers understand *e* equally well, and yet associate it with different inferential roles. That being said, however, semantic holism is a highly controversial view (Dummett, 1991; Pagin, 1997). Let us therefore consider possible lines of response in defense of non-holistic versions of UND.

Boghossian (2012a) has recently suggested the following inferentialist response. In his view, McGee understands 'if,' but he understands it differently. His deviant use simply shows that he attaches a different meaning to 'if.' As he puts it:

> All that the inferential role theorist is committed to saying is that, if [Vann] succeeds in altering his behavior with ['if'] and flouts a meaning-constituting rule […], then he necessarily means something different by 'if' […] It is better to call this "meaning change" rather than incompetence. (Boghossian, 2012a, p. 232)

As it stands, however, Boghossian's response is problematic. It is premised on an idiolectic version of MD (see 2012a, p. 233, fn. 2) which is flatly inconsistent with the social externalism assumed by Williamson's criticism. It may be that such idiolectic conceptions are ultimately more congenial to the inferentialist. Yet, it is an interesting question whether the inferentialist can respond to Williamson on his own terms. While we lack the space to develop a full response, we canvass the general shape such a response might take.

We begin with the observation that Boghossian's meaning-change approach is especially compelling in cases that are very similar to the ones Williamson considers. Consider, for instance, the case of a full-blooded intuitionist and of a classical logician – call them Michael and Tim, respectively – and let us assume that they are both highly proficient logicians. Arguably, Michael and Tim have a different understanding of 'not' (DeVidi and Solomon 2001; Dummett 2007; 2009).[29] It might be argued, then, that it would be problematic to insist, faced with such a difference, that intuitionist and classical logicians have the same *understanding* of 'not.' After all, intuitionists consciously use 'not' differently. For instance, unlike classical logicians, they refuse to assent to certain instances of the Law of Excluded Middle. It would not do justice to their semantic beliefs to insist that, in spite of their avowed intention to use 'not' according to its intuitionist meaning, 'not' means classical negation in their mouth. Intuitionists *reject* the classical meaning of 'not,' and *there is* a coherent, if arguably ultimately untenable, intuitionist meaning of 'not.' The same, it might be contended, applies to the McGee case.

But wouldn't this be, once again, inconsistent with Williamson's social externalism? Here it helps to observe that both Michael and Tim are, we are assuming, experts who have very close to full understanding. What makes them experts is that they are able to make authoritative pronouncements – what Burge (1986) calls 'normative characterizations' – regarding the criteria for correctly applying expressions related appropriately to their area of competence. They are in the business of *investigating and explicitly articulating the rules we ought to follow*. They are, in Kaplan's distinction, language 'creators' as opposed to mere 'consumers' (Kaplan, 1989a, p. 602). And since they can help shape a linguistic community's linguistic standards,

in view of their divergences in the use of 'not,' they may be plausibly viewed as belonging to different linguistic communities. It will not do to insist, as Williamson does, that small differences in use don't make a difference in understanding. In the present context, they do. It is only natural that the pronouncements of two experts be carefully examined. Even a small difference in the rules governing the use of an expression *e* is likely to imply a difference in that expression's content, on the natural assumption (shared by all parties) that such a content validates the rules for *e*'s correct use.

So much, then, for experts. What should the inferentialist say about Joe Shmoe's small but systematic deviance with respect to a given expression *e*? Wouldn't it be patronizing to claim that, because he doesn't conform to the community-wide use of *e*, he doesn't understand *e* (Williamson, 2003; 2007)? Here one should consider two cases. If Joe *defers to experts*, that is, if, for instance, he is disposed to be corrected by them, then it is open to the inferentialist – in keeping with Williamson's social externalism – to maintain that it is the experts' dispositions that determine *e*'s meaning, and that are constitutive of Joe's understanding of *e*. If, on the other hand, Joe does not defer to experts, and stubbornly insists in using *e* in a deviant way, then it would seem appropriate to say that Joe indeed has an idiosyncratic understanding of *e*: he understands *e* differently.

The inferentialist, then, might respond to Williamson's challenge by insisting that his examples all involve a discrepancy in use among *experts*. Williamson's key argumentative move, the inferentialist might diagnose, is to treat experts as *non-experts*, and to discard, *for this reason*, their idiosyncratic use of certain expressions as irrelevant for those expressions' meaning and understanding. Yet, by the social externalist's own lights, experts – language creators – who use a given expression in different ways, should be credited with *different understandings* of that expression.

If the foregoing considerations are along the right track, it would seem that Williamson's central objection to IRS misses its target after all. To be sure, much more remains to be said. For instance, the inferentialist who pursued a response to Williamson along these lines would have to explain how, for instance, rival logicians might be able to disagree about the validity of what would intuitively seem to be the same logical law. A disagreement about the Law of Excluded Middle, on the foregoing view, would no longer be about whether $A \vee \neg A$ is valid or not, but, say, about whether 'not' and 'or' in English should be interpreted classically or intuitionistically. The question whether this is a plausible feature of the view, or an unpalatable consequence, is, as far as we can see, still very much open.

Notes

1 Many thanks to Alex Miller for very helpful comments on a first draft of this paper. Over the years, we have greatly benefited from conversations we had with a number of friends and colleagues on inferentialism and related topics. We'd like to thank in particular Corine Besson, Paul Boghossian, Cesare Cozzo, Salvatore Florio, Dominic Gregory, Bob Hale, Ole T. Hjortland, Luca Incurvati, Rosanna Keefe, Hannes Leitgeb, Dag Prawitz, Stephen Read, Ian Rumfitt, Gil Sagi, Neil Tennant, Tim Williamson, and Crispin Wright.

2 Stalnaker (1997) uses the labels 'descriptive semantics' and 'foundational semantics' to make the same distinction. We follow the terminology in Kaplan (1989a), which by now is fairly well established. Brandom's labels 'formal semantics' and 'philosophical semantics' seem to designate the same distinction. See Brandom (1994, p. 143) and Weiss and Wanderer (2010, p. 342) for formulations of Brandom's distinction.

3 The level of thought is treated analogously:

(CD) *Content determination*. The contents of concepts are determined by their role in inference.

(GRA) *Grasping*. To grasp a concept is to know its role in inference.

4 See, e.g., Brandom's deflationary notions of reference and truth in his (1994), as well as the discussion between Dummett and Brandom (Weiss and Wanderer, 2010, chs 13 and 29).

5 That said, certain local forms of IRS do proclaim a (local) atomism. Neil Tennant (1987; 1997), for instance, argues for a form of atomistic IRS about logical concepts. On such a view, the meaning of any logical operator is independent of that of the other logical operators (indeed independent of any other expressions). Analogously, understanding a logical operator does not presuppose antecedent understanding of any other logical operators.

6 But see our discussion of Brandom's holism in § 3 below.

7 Block (1986), Loar (1981), Harman (1999), and Peacocke (1992) belong to this camp.

8 Proponents of normative versions of IRS include Boghossian (2003a), Brandom (1994), Dummett (1991), Wedgwood (2007), Whiting (2009).

9 See, e.g., Popper (1947, p. 220), Kneale (1956, pp. 254–255), and Dummett (1991, p. 247).

10 Dummett correctly observes that while

> it may […] be that the [representational] meanings of the logical constants [i.e., the truth-functions they denote] are *determined* by the logical laws that govern their use in deductive arguments […] this cannot be assumed – it needs to be *shown*. (Dummett, 1991, p. 205)

Carnap (1943) first showed that, in standard natural deduction systems, the rules for $\vee$, $\neg$, and $\rightarrow$ fail to determine their standard truth-conditions. Thus, it would seem, standard natural deduction systems are not hospitable at least to certain interpretations of MD. However, while this is sometimes thought to be a problem (see, e.g., Raatikainen, 2008), it need not be. For one thing, on certain assumptions, the rules still determine the standard *intuitionistic* meanings of $\vee$, $\neg$, and $\rightarrow$ (Garson, 2001). For another, in slightly less standard, though arguably equally 'natural,' natural deduction systems, the classical I- and E-rules for $\vee$, $\neg$, and $\rightarrow$ *do* determine their truth-conditions (see, e.g., Smiley, 1996; Rumfitt, 2000).

11 For instance, a connective $\odot$ satisfying the standard I-rules for $\wedge$ but only one of its E-rules would be intrinsically harmonious, and yet intuitively disharmonious: its E-rule would not allow us to infer from $A \odot B$ all that was required to introduce $A \odot B$ in the first place.

12 Right-to-left: suppose B follows from A. Since A also follows from $CG[A]$, B itself follows from $CG[A]$. Left-to-right: suppose B follows from $CG[A]$. Now assume A. By the Fundamental Assumption, $CG[A]$ itself follows. Hence, on our assumption that B follows from $CG[A]$, we may conclude B, as required.

13 Whether harmony is also a *sufficient* condition for logicality is a more delicate question. See Read (2000).

14 See, also e.g., Hacking (1979, pp. 296) and Dummett (1991, pp. 217–218), and the discussion in Steinberger (2011a).

15 Alternatively, harmonious axiomatizations of classical logic can be given once *multiple conclusions* are allowed (Read, 2000; Cook, 2005), either in a natural deduction or in a sequent-calculus setting. Sequent calculi axiomatizations of intuitionistic and classical logic are exactly alike, except that classical sequent calculi allow for sequents with multiple premises *and* multiple conclusions. In turn, such sequents can be plausibly interpreted as saying that one may not assert all the antecedents and deny all the succedents, where, again, assertion and denial are both primitive speech acts (Restall, 2005). For a technical introduction to multiple-conclusion logics, see Shoesmith and Smiley (1978). For a recent criticism, see Steinberger (2011b).

16 We should stress that Brandom is but one proponent of a global form of inferentialism. For some representative publications on various global brands of IRS, see, e.g., Sellars (1956), Harman (1987), Field (1977; 1994; 2001), Block (1987; 1998), Cozzo (1994), Horwich (1998), Peacocke (1992), Boghossian (2003a; 2003b; 2012a; 2012b), Whiting (2006; 2008; 2009), Chalmers (2014). For reasons of space, we only focus on Brandom's work, on account of its influence, and of the detail in which the views have been worked out over the years.

17 For a criticism of Brandom's deflationary approach see Shapiro (2004). See MacFarlane (2010) for an interesting objection to Brandom's assumption that a use-theoretic approach is incompatible with a truth-conditional approach.

18 As we noted in section §2, there will be extremal cases – language-entry rules – in which the grounds for inferring a sentence may be perceptual; and in which the consequences of asserting a sentences will be non-linguistic.

19 Brandom explicitly follows Sellars on this point Brandom (1994, p. 97).

20 See in particular Brandom's discussion of Dummett's inferentialist treatment of pejoratives (Brandom, 2000, pp. 69ff.). See Williamson (2009) for a stern referentialist reprisal.

21 The exchange between Hale and Wright and Brandom is illuminating in this regard. See Weiss and Wanderer (2010, chs 17 and 33).

22 For an impression of the breadth of criticisms inspired by his (Brandom, 1994) alone, readers may consult, e.g., the book symposium in a special issue of *Philosophy and Phenomenological Research* (vol. 57, no. 1, 1997), and Weiss and Wanderer (2010).

23 For more discussion on semantic holism, see, e.g., Dummett (1991), Harman (1993), Pagin (1997; 2009), Cozzo (2002).

24 See Brandom (1994, p. 666) for more detailed discussion.

25 For an incomplete sample, see, e.g., Fodor and Lepore (1991), Casalegno (2004), Williamson (2003; 2007; 2009; 2012), Horwich (2005), Besson (2012), Schechter and Enoch (2006), Dogramaci (2012). For some inferentialist responses beyond the ones cited below, see, e.g., Eklund (2007), Balcerak Jackson (2009), and Murzi and Steinberger (2013).

26 The same point is also forcefully made, *inter alia*, in Jason Stanley's introduction to Stanley (2007).

27 See also Williamson (2007, p. 282).

28 If McGee is right, and 'if' actually does not satisfy MP, contrary to what we're assuming, then expert speakers who infer according to the unrestricted rule of MP would serve as purported counter-examples to UND.

29 Intuitionist and classical negation (respectively, $\sim$ and $\neg$) have different meanings on most intuitionist semantics. For instance, on the standard BHK (Brouwer–Heyting–Kolmogorov) semantics $\sim A$ means that there is no proof of A, i.e., that it is *impossible* to prove A. Given the intuitionist's equation of truth with the existence of a proof, the impossibility of proving A in turn entails that A *can't* be true. Similarly, on the standard Kripke semantics for intuitionist logic, $\sim A$ is forced by a state of information w if and only if *no possible development* of w forces A. This modal component is arguably absent in classical negation (DeVidi and Solomon, 2001; Dummett 2007; 2009).

Against Harmony

IAN RUMFITT[1]

In both natural deduction and sequent formalizations of logical systems, each connective is associated with an introduction rule and an elimination rule. The introduction rule for the connective **C** is one which licenses the derivation *of* a formula dominated by **C**; the elimination rule is one which licenses the deduction of further conclusions *from* such a formula, often with other formulae as auxiliary premises. In the sense of the term with which I shall be concerned, *harmony* is a particular relationship between the introduction rule and the elimination rule for a given connective. Whether the rules of a logical system are harmonious is certainly of great interest to proof theorists, but I am concerned with a philosophical claim about the notion. The *Harmony Thesis*, as I shall call it, says that a connective is defective unless its associated introduction and elimination rules are in harmony. It also says that a connective is defective if the logical principles which regulate its use go beyond a pair of harmonious introduction and elimination rules. Most proponents of the Harmony Thesis have, indeed, a particular defect in mind. On their view, a connective will not possess a sense – it will not have a coherent meaning – unless its logical behavior is regulated only by a pair of harmonious introduction and elimination rules.

The Harmony Thesis is connected to wider claims in the philosophy of language and the philosophy of logic. According to *Inferential Role Semantics* (IRS), the meaning of a complete statement is determined by its role in inference, and the meanings of sub-sentential expressions are determined by their contribution to the inferential roles of complete statements in which they figure. As Julien Murzi and Florian Steinberger remark in their contribution to this volume (see Chapter 9, INFERENTIALISM), many adherents of IRS appeal to the Harmony Thesis in order to circumscribe the range of meaning-determining inferential roles. We have yet to see what harmony comes to, but it is also widely held that the classical introduction and elimination rules for negation violate the Thesis, so Harmony is often invoked in challenges to classical logic. Dummett's *The Logical Basis of Metaphysics* provides a famous example of this. He holds that a connective's introduction and elimination rules must be in harmony if the connective is to make sense. So he takes the perceived lack

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

of harmony between the classical rules for negation to be "a strong ground for suspicion that the supposed understanding [of classical negation] is spurious" (Dummett, 1991, p. 299).

In this chapter, I want to scrutinize the most influential arguments which have been put forward for the Harmony Thesis. I find these arguments wanting, so my conclusion will be that the Thesis is not well supported. Any rejection of it must be provisional: tomorrow, someone may come up with a brilliant new argument which will persuade us all that there is a requirement of harmony on any intelligible connective. But I doubt it. As the analysis will reveal, the most popular arguments for the Harmony Thesis are not near misses which might succeed with a bit of tweaking. Rather, they are superficially plausible arguments which turn out, on closer examination, to rely upon highly dubious premises from epistemology and the theory of meaning. My analysis will not challenge the claim that deductive systems exhibiting harmony have attractive proof-theoretical features; to the contrary, I regard that claim as obviously true. But a connective may possess a sense, and may in other ways be non-defective, without generating those nice features, so the proof-theoretic elegance of harmonious rules does not settle the philosophical questions I am addressing. I conclude by discussing briefly how the failure of the Harmony Thesis affects the prospects for IRS.

1 The Inversion Principle

I have been using the term 'harmony,' but what exactly does it mean? As we shall see, different parties mean rather different things by it. I start by expounding what I take to be the most prominent version of the Harmony Thesis.

Central to this version is the claim that a connective's introduction rule determines its sense or meaning. The claim goes right back to Gentzen, who wrote that "the introduction rules represent, so to say, the 'definitions' of the signs in question [i.e., the connectives and quantifiers], and the elimination rules are, in the final analysis, no more than consequences of these definitions … In eliminating a sign, we may use a formula which has that sign as its main connective only with the meaning afforded it by the sign's introduction rule" (Gentzen, 1935, p. 189/1969, p. 80). Prawitz (see especially 1974), Dummett (see 1991), and Negri and von Plato (2001) also accept this claim.

What, exactly, are introduction rules and elimination rules? As we shall see, some delicate issues surround this question, but an initial answer runs as follows. While they may be extended to natural languages, the notions were originally applied to formalized languages, so let us consider for simplicity a propositional language L with sentence letters P_1, P_2, …, and a collection of finitary connectives. A *sequent* is then defined to be an expression $X \Rightarrow A$, where A is a formula of L and X is a finite set (possibly empty) of such formulae.[2] Where $n \geq 0$, consider the $(n+1)$-tuple of sequents $<X_1 \Rightarrow A_1, \ldots, X_n \Rightarrow A_n, Y \Rightarrow B>$. This determines an $(n+1)$-ary *rule for sequents* (for short, a *rule*), comprising all substitution instances of the $(n+1)$-tuple. This rule is understood as licensing the passage from any substitution instance of the first n sequents (the *premise sequents*) to the corresponding instance of the last sequent (the *conclusion sequent*). We mark the division between the premise and conclusion sequents with the solidus, /. When $n = 0$, we have a *rule of inference*, such as $\wedge$-introduction:

$$/P_1, P_2 \Rightarrow P_1 \wedge P_2$$

(when displaying particular rules, I shall often omit the angled brackets around tuples). When $n \geq 1$, we have a *rule of proof*, such as $\rightarrow$-introduction:

$$X, P_1 \Rightarrow P_2 / X \Rightarrow P_1 \rightarrow P_2.$$

A rule is *elementary* if all its members are substitution instances of a tuple $X_1 \Rightarrow A_1$, …, $X_n \Rightarrow A_n / Y \Rightarrow B$ such that (a) all the formulae in all the sequents are sentence letters except for at most one, which is of the form $\mathbf{C}(P_1, \ldots, P_k)$ for some k-place connective **C**; and (b) this complex formula $\mathbf{C}(P_1, \ldots, P_k)$ (if it appears at all) occurs either on the left or the right of the conclusion sequent $Y \Rightarrow B$. If it occurs on the right of $\Rightarrow$, the elementary rule in question is an *introduction rule* for **C**. If it occurs on the left, it is an *elimination rule* for **C**.[3]

On this account, the rule of double negation elimination (*DNE*) – from $\neg\neg A$, infer A – does not qualify as an elimination rule. While this consequence may initially seem surprising, it is to be welcomed. Gentzen described *DNE* as an elimination rule: *DNE*, he wrote, "represents a new elimination of negation whose admissibility does not follow at all from our way of introducing the negation sign by the ¬-*I* rule" (Gentzen, 1935, p. 190/1969, p. 81). Dummett followed him in this. Indeed, Dummett's critique of classical logic in *The Logical Basis of Metaphysics* is really an extended elaboration of the sentence just quoted from Gentzen: the classical elimination rule for negation, *viz. DNE*, is not in harmony with its introduction rule. But *DNE* does not conform to Dummett's own account of what an elimination rule is. In applying *DNE* we pass, of course, to a conclusion that contains two fewer occurrences of '¬' than does the premise, but that is not enough for it to count as an elimination rule. "In the case of a logical constant, we may regard the introduction rules governing it as giving the conditions for the assertion of a statement of which it is the main operator, and the elimination rules as *giving the consequences of such a statement*" (Dummett, 1981, pp. 454–455; emphasis added). The *DNE* rule tells us nothing *in general* about the consequences of statements in the form $\ulcorner\neg A\urcorner$. It tells us something only about the very special case of statements in the form $\ulcorner\neg\neg A\urcorner$. It is to the good, then, that the proposed account does not classify *DNE* as an elimination rule.

In what sense might an introduction rule for **C** be thought to *define* **C**? Gentzen did not say but, according to Prawitz and Dummett, it does so by specifying the *direct grounds* (alias the 'canonical' grounds) for asserting a formula dominated by **C**. Suppose that G_1 is a direct ground for asserting the interpreted formula A and that G_2 is a direct ground for asserting the interpreted formula B. Then the rule of $\wedge$-introduction tells us that the combination of G_1 with G_2 constitutes a direct ground for asserting the conjunctive formula $\ulcorner A \wedge B\urcorner$. Indeed, if this rule is to *define* the sense of '$\wedge$,' it must be understood as telling us that the *only* direct grounds for asserting $\ulcorner A \wedge B\urcorner$ are those which combine a direct ground for A with a direct ground for B. The introduction rule for '$\vee$' is $<P_1 / P_1 \vee P_2> \cup <P_2 / P_1 \vee P_2>$. In a similar way, this rule is to be read as telling us that a direct ground for asserting a disjunctive formula $\ulcorner A \vee B\urcorner$ will be either a direct ground for A or a direct ground for B. As remarked, the rule of $\rightarrow$-introduction is a rule of proof, not a rule of inference, so here matters are less straightforward. But $\rightarrow$-introduction is understood as telling us that a direct ground for asserting $\ulcorner A \rightarrow B\urcorner$ is a method for transforming any ground for A into a ground for B. There are of course grounds for assertion – indeed, conclusive grounds for assertion – which are not direct. Thus we might assert $\ulcorner A \wedge B\urcorner$, not on the basis of the combination of G_1 with G_2, but on the strength of a deduction of $\ulcorner A \wedge B\urcorner$ from the premises C and $\ulcorner C \rightarrow A \wedge B\urcorner$.

Any development of this theory of direct or canonical grounds clearly faces problems. For one thing, the method that constitutes a direct ground for asserting $\ulcorner A \rightarrow B\urcorner$ needs to be one that transforms *any* ground for A into a ground for B, so the specification of direct grounds would appear not to be straightforwardly compositional.[4] It is, however, in the context of this conception of the meaning of the connectives that the present version of the Harmony Thesis belongs. For suppose that the meaning of a connective **C** is given by its introduction rule; then the elimination rule for **C** must be faithful to that meaning.

In Gentzen's words, we may use **C** only with the meaning that the introduction rule affords it. On this view, the requirement of harmony does no more than spell out what such fidelity consists in. Gentzen conveys the requirement he has in mind only by way of an example: "if we wished to use [the formula $\ulcorner A \rightarrow B \urcorner$] by eliminating the $\rightarrow$-symbol … we could do this precisely by inferring B directly, once A has been proved, for what $\ulcorner A \rightarrow B \urcorner$ attests is just the existence of a derivation of B from A" (Gentzen, 1935, p. 189/1969, pp. 80–81, with incidental changes in the symbolism). Negri and von Plato, though, spell out the general principle to which Gentzen implicitly appeals. To find the elimination rule which is faithful to a given introduction rule, they write, "we ask what the conditions are, in addition to assuming the major premiss derived, that are needed to satisfy the *Inversion Principle*:

> Whatever follows from the direct grounds for deriving a formula must follow from that formula. (Negri and von Plato, 2001, p. 6; I write 'formula' where they have 'proposition')

According to the present version of the Harmony Thesis, then, a non-defective logical connective must be regulated only by a pair of introduction and elimination rules which satisfy the Inversion Principle. This version of the Thesis is justified by the claim that the elimination rule for a connective must be faithful to the introduction rule that defines the connective's meaning. One finds similar, albeit less explicit, formulations of this version of the Thesis, and of the suggested justification for it, in Prawitz and Dummett.[5]

One merit which Negri and von Plato claim for their formulation is that it not only justifies a certain elimination rule, given an introduction rule, but "actually determines what the elimination rules corresponding to given introduction rules should be" (2001, p. xvi).[6] Take disjunction as an example. The direct grounds for $\ulcorner A \vee B \urcorner$, we saw, are either direct grounds for A or direct grounds for B. The Inversion Principle is understood to say that whatever follows from *any* of the direct grounds for asserting a formula must follow from that formula. So we reach the $\vee$-elimination rule in the form: given a derivation of C from the assumption A, and another derivation of it from the assumption B, we may derive C from the disjunction $\ulcorner A \vee B \urcorner$. This is, in fact, the form of $\vee$-elimination that Negri and von Plato take their Inversion Principle to yield (2001, p. 7) and they go on to show how to excise from a derivation any deductive steps in which an instance of $\vee$-introduction is immediately followed by an instance of $\vee$-elimination. Suppose, for example, that we apply $\vee$-introduction to derive $\ulcorner A \vee B \urcorner$ from A, and then immediately eliminate $\ulcorner A \vee B \urcorner$ to reach the conclusion C. The derivation will then have the form

$$\dfrac{\begin{array}{ccc}\Delta & A & B \\ A & \Delta' & \Delta'' \\ A \vee B & C & C\end{array}}{C}$$

and we may simplify it by cutting out the occurrence of $\ulcorner A \vee B \urcorner$ entirely, thereby reaching

$$\begin{array}{c}\Delta \\ A \\ \Delta' \\ C\end{array}$$

This is an example of what Prawitz labels a 'reduction step' and of what Dummett calls 'levelling a local peak.'

There is, however, a problem here. The form of ∨-elimination that Negri and von Plato's Inversion Principle yields is the restricted version of the rule found in quantum logic, in which the conclusion *C* must be derived from *A*, and from *B*, without the use of any side premises.[7] However, only a few pages later in their treatise on proof theory (2001, p. 15), they blithely reformulate the elimination rule in the form *with* side premises: it is this stronger form of the rule that is found in classical, intuitionistic, and indeed minimal logic. It is hard to see what justifies the switch: in identifying the elimination rule that matches a given introduction rule, Negri and von Plato tell us, we are to "ask what the conditions are … that are *needed* to satisfy the Inversion Principle" (2001, p. 6, with emphasis added): the 'needed' seems to imply that we are to select the *weakest* elimination rule which satisfies Inversion.[8] I shall return to this problem in due course.

2 An Argument for the Inversion Principle

First, though, we should consider the central question which this attempted justification of the Harmony Thesis raises: why should we accept the Inversion Principle?

At first blush, there seems to be a compelling argument for the Principle. As we have seen, it is to be read as saying: 'Whatever follows from *any* of the direct grounds for asserting a formula must follow from that formula.' Let *C* be a formula which follows from any of the direct grounds for asserting a formula *A*, and suppose that *A* is asserted. If *A* has been correctly asserted, one might think, then at least one of its direct grounds must obtain. *Ex hypothesi*, *C* follows from any such ground. So *C* must obtain if *A* has been correctly asserted. *C*, then, is a commitment of a correct assertion of *A*, and as such – one might think – *C* must follow from *A*. So far from being compelling, however, this argument faces two severe problems.

First, and most obviously, the argument implicitly rejects the view that consequence is a matter of the preservation (or necessary preservation) of *truth* in favor of a view whereby consequence is a matter of the preservation (or necessary preservation) of correct *assertibility*. For suppose one did think that consequence was a matter of the preservation of truth. In that case, the proposed justification of Harmony would scarcely get started. On this view, in order to argue that *C* follows from *A*, we would need to show that *C* is true given only the assumption that *A* is *true*. From the assumption that *A* is true, however, it does not follow that any direct ground for asserting *A* obtains. Indeed, it does not follow that *any* ground for asserting *A* obtains. For all that has been said, the formula *A* might be true but unassertible. Only if consequence is understood to consist in the preservation of correct assertibility, then, does the mooted argument so much as get going. On that alternative view of consequence, in seeking to show that *C* follows from *A*, we *shall* start by assuming that *A* is correctly asserted.

A second problem confronts the argument, though, even if we do take consequence to consist in the preservation of correct assertibility rather than in the preservation of truth. On this view, in trying to show that *C* follows from *A* we shall start by assuming that *A* is correctly asserted, from which it follows that some ground for asserting *A* obtains. What we are given about *C*, though, is that it follows from any *direct* ground for asserting *A*. So in order to conclude from our assumption that *C* obtains, we shall need a premise to the effect that whenever a ground for asserting a formula obtains, some *direct* ground for asserting it obtains. It is far from obvious what is supposed to support this additional premise. Indeed, pending further explanation of what a 'direct' ground is, it is far from clear what the additional premise means.

In view of this unclarity, one might be tempted to delete the word 'direct' from the formulation of the Inversion Principle altogether, so that it now says simply: 'Whatever follows from any of the grounds for asserting a formula must follow from that formula.' The resulting position, however, does not at all fit the view we are considering, whereby the introduction rule for a connective is held to specify that connective's meaning. At least, it does not fit this view if the rules in question are to be the familiar introduction rules for the connectives. On this version of the view, the rule of $\vee$-introduction would imply that there are grounds for asserting the disjunction $\ulcorner A \vee B \urcorner$ if and only if there are grounds for asserting A or grounds for asserting B. And the 'only if' part of this claim is simply false, at least if the symbol '$\vee$' is supposed to have even roughly the same meaning as the English word 'or.' As Dummett noted in his early paper "Truth" (1959), the claim is wholly unsustainable if we allow that the testimony of others can provide grounds for assertions. Reliable sources from the Egyptian Fourth Dynasty tell us that the Pharaoh Cheops (whom Egyptologists now call 'Khufu') was either the son or the stepson of his predecessor on the throne, the Pharaoh Sneferu. Those sources, then, provide grounds for that disjunctive assertion. There are, though, no reliable grounds for asserting either disjunct. Indeed, there are other counter-examples to the 'only if' claim which do not rely on knowledge by testimony. If Inspector Morse knows (from the position of wounds on the victim) that the murderer is left-handed, and that Smith and Jones are the only left-handers among the possible culprits, then he has grounds for asserting 'Either Smith or Jones is the murderer.' In that circumstance, though, Morse may have no grounds for asserting either 'Smith is the murderer' or 'Jones is the murderer.' What we see, then, is that the present argument for the Inversion Principle depends upon finding a sense for the word 'direct' (or 'canonical') which treads a fine line. The sense has to be sufficiently generous to ensure that whenever a ground for asserting a formula obtains, a direct ground obtains. At the same time, it has to be sufficiently restricted to ensure that a direct ground for asserting $\ulcorner A \vee B \urcorner$ involves either a direct ground for A or a direct ground for B. The introduction rules for the other connectives will impose corresponding restrictions on the acceptable sense of 'direct.'

3 Problems with the Argument

What are the prospects of overcoming these problems so that the present argument for Inversion can be vindicated? I address the problems in turn.

There is no doubt that the conception of consequence on which the argument rests deviates from the conception which has animated logic since its creation. The key mark of a valid argument is that its conclusion is true whenever all its premises are true. At the heart of consequence, then, lies preservation of truth, not preservation of correct assertibility, or of knowability, or of anything other than truth. While disputes persist about the proper explanation of consequence, those disputes center on what surrounds that heart: notably whether consequence involves the necessary preservation of truth (as Aristotle held) or whether actual preservation will do (as Russell thought); and whether the sort of truth-preservation which is characteristic of logical consequence must be rooted in a formal relationship between premises and conclusion. If an explanation of consequence in terms of the preservation of correct assertibility is going to be more than an eccentric misuse of the familiar notion, we must take ourselves to be in a dialectical context in which truth has already been 'dethroned' (as people used to say) from its usual place in that explanation.

More particularly, we must presume that powerful arguments have already been given for explaining consequence in terms of the preservation of correct assertibility.

Supposing for a moment that some powerful arguments to this effect have been given, the foundations of logic will certainly need reconstruction. Logicians prove soundness theorems for various logical systems. That is, they show that, if the rules of a given system are followed, then the conclusion is true in every possible circumstance in which all the premises are true. But what can soundness come to if truth has been dethroned? There must still be some standard against which individual deductions, rules, and indeed whole logical systems may be assessed. We still want to be able to say that someone who infers 'If Fred works hard, he will get a First; Fred will get a First; therefore Fred works hard' has reasoned unsoundly – that he has made a logical mistake. But in what does his mistake consist if not in the possibility that both premises might be true when the conclusion is not true?

It may be answered that we can still give an account of why the reasoner is making a mistake in terms of correct assertibility. Our reasoner's argument is unsound because someone could be in a position correctly to assert both the premises without being in a position correctly to assert the conclusion. But this just pushes the problem back: we shall then need to specify the conditions for correctly asserting the sentences or formulae of the relevant language. On any view, the introduction of logical connectives into a language that has hitherto lacked them is going to create new grounds for asserting formulae. This applies to atomic formulae as well as to molecules: once the language contains a conditional, for example, we can correctly assert an atomic formula B by (for example) deducing it from correct assertions of A and of ⌜If A then B⌝. But given that any logical rules are going to generate new grounds for assertions, we have to say what it is for *modus ponens* to constitute an acceptable expansion of those grounds while affirming the consequent does not. Moreover, the proponent of the present argument for Harmony has to give an account of this matter without falling back on the idea that a valid argument preserves truth.

The only developed account of this that I know relies heavily on the distinction between direct and indirect grounds for assertion. The thought is that, while logic certainly yields new indirect grounds for atomic assertions, its rules must be faithful to the *direct* grounds of formulae: we shall have an instance of consequence only if any direct grounds for the premises could be transformed into a direct ground for the conclusion. This is the account of logical consequence shared by Prawitz (see especially his 1974) and Dummett (see especially his 1991). Instead of direct grounds for atomic formulae, Prawitz writes of valid 'closed' arguments for them. He duly "defines a sentence B as a logical consequence of sentences A_1, …., A_n by the existence of an operation φ which for every choice C [of valid closed arguments] transforms any closed arguments for sentences A_1, …., A_n valid relative to C to a closed argument for B valid relative to C" (Prawitz, 1974, pp. 74–75). Dummett proposes essentially the same account. "We regard [Euler's] proof as showing us, of someone observed to cross every bridge at Königsberg, that he crossed at least one bridge twice, *by the criteria we already possessed for crossing a bridge twice*" (1991, p. 219, emphasis in the original). "If that is what deductive inference achieves," he continues, "the requirement of harmony springs from its very nature. When an expression, including a logical constant, is introduced into the language, the rules for its use should determine its meaning, but its introduction should not be allowed to affect the meanings of sentences already in the language" (1991, p. 220). By mastering logic we acquire new indirect grounds for making assertions. But the methods we master must be faithful to the meanings of the atoms in that they preserve their conditions of direct assertibility.

If consequence is to be explained in terms of the preservation of some form of correct assertibility, it is hard to think of any other account than the one which Prawitz and Dummett provide. That account, though, generates serious problems – problems which, I now argue, are so serious as to cast doubt upon the hypothesis that consequence *can* be explained in this way.

Euler's proof is said to show us, of someone observed to cross every bridge at Königsberg, that he crossed at least one bridge twice, *by the criteria we already possessed for crossing a bridge twice*. But that cannot mean that those criteria have actually been applied to verify that our promenader crossed a bridge twice. Perhaps they were so applied – perhaps an observer stationed on the Dombrücke, for example, saw him cross that bridge twice – but Euler's proof would not be refuted if the pre-existing criteria were not actually applied. The most that can be claimed is a counterfactual: had an observer been stationed on each bridge, with instructions to tick a box if, and only if, the promenader was observed crossing it twice, then at least one observer would have ticked his box.

This counterfactual claim, however, is susceptible to objections parallel to those which afflict putative counterfactual analyses of other categorical notions. Some philosophers used to say that an object is yellow if an observer with good eyesight, viewing it in white light, would perceive it as yellow. Saul Kripke objected that this account was inconsistent with something that is surely a metaphysical possibility – namely, the existence of *killer yellow*, a shade of yellow that kills any observer who looks at it in white light.[9] In much the same way, Dummett's account of the validity of Euler's proof is inconsistent with the existence of *Königsberg ennui*, a strange neurological condition which ensures that anyone trying to observe whether a promenader has crossed a given bridge twice will fall into a catatonic state before any second crossing. Like killer yellow, Königsberg ennui is surely a metaphysical possibility. In a possible world where the denizens of Königsberg are afflicted by it, however, it will not be true to say that at least one of our observers would have ticked his box, had the promenader crossed every bridge. Even in such a world, however, 'The promenader crossed at least one bridge twice' still follows from 'He crossed every bridge.'

Even if we prescind from this rather general doubt, other worries press in fast, especially when we turn to our second main problem and reflect on the role which the distinction between direct and indirect grounds needs to play in the present argument for the Harmony Thesis. The notion of directness needs to be sufficiently generous, we said, that no ground for asserting a formula obtains unless a direct ground for asserting it could have obtained. Yet the direct grounds for asserting a complex formula are constrained to be those given by the introduction rule for the formula's main connective. Combining these points, we deduce that no ground for asserting a complex formula can obtain unless the assertion of that formula could have been justified by applying the introduction rule for its main connective. In other words, the present argument for the Harmony Thesis rests upon what Dummett calls the *Fundamental Assumption*.

Dummett is clear that the present argument does rest upon this Assumption. His discussion, though, does not inspire great confidence in the Assumption's truth. The Assumption is tenable, I think, in the case of conjunction. If someone is entitled to assert $\ulcorner A \wedge B \urcorner$, then he is entitled to assert A and is also entitled to assert B, so his assertion of the conjunction could have been grounded in an application of the $\wedge$-introduction rule. For none of the other familiar sentential connectives, though, is the Fundamental Assumption remotely plausible.

In the case of disjunction, Dummett recognizes that the Assumption is quite untenable if we confine ourselves to the grounds available to an individual thinker. While I have a

ground for asserting 'Cheops was either the son or the stepson of Sneferu,' it is impossible for me to justify that disjunctive assertion by an argument which concludes with an application of the introduction rule for 'or.' The Assumption is only tenable, Dummett holds, if the grounds for making an assertion are taken to include those available to any of *us*, where "whatever witnesses we trust must be included among 'ourselves'" (1991, p. 266). Thus the ancient scribe who recorded that Cheops was either the son or the stepson of Sneferu is one of us, and the Fundamental Assumption tells us that his assertion is correctly made only if he knew which it was, or if he was himself told the disjunction by someone who knew which disjunct obtained.

Perhaps we can swallow *this* consequence of the Assumption. Other consequences, though, are far less palatable. Consider the assertion 'At the moment when Brutus first stabbed Caesar in Pompey's Theatre, there was either an odd or an even number of people in the Agora in Athens.' Let us assume that the space of the Agora has been precisely delimited, and that precise rules have been laid down for when a person counts as being *in* a space. Given that assumption, most of would think ourselves entitled to make the present disjunctive assertion. If we are so entitled, though, the Fundamental Assumption entails that someone – that is, some one of us – could have been in a position either to assert 'At the moment when Brutus first stabbed Caesar, an odd number of people were in the Agora' or to assert 'At that moment, an even number of people were there.'

Dummett acknowledges, of course, that no one actually was in a position to make either of these claims. "To interpret the fundamental assumption," he writes, "we have to invoke the sense of 'could have' which was used earlier to characterize what may be called the minimal undeniable concession to realism demanded by the existence of deductive inference" (1991, p. 267). In the case of statements about the past, he continues, this means "that a sufficient condition for [an assertion's] correctness is that there exist effective means by which, at the relevant time, someone appropriately situated *could have* converted observations that were actually made into a verification of the statement asserted" (1991, p. 268). By the Fundamental Assumption, though, a closely related condition must be *necessary*: for an assertion to be correct, it is necessary that someone appropriately situated could, at the relevant time, have made observations which would have justified it. In the case of either of our two disjuncts, though, it is hard to see how this necessary condition could be satisfied. For where would an observer be 'appropriately situated'? An observer in Pompey's Theatre would have been well placed to notice when Brutus stabbed Caesar and to observe what was happening at that moment in that part of Rome; but he was not in a position to count how many people were then in the Athenian Agora. An observer situated in the Agora, by contrast, may have been in a position to make a count of those present in the square; but he would not know when to do so. What a direct ground for either disjunct needs is a *pair* of observers, with the first able to effect a practically instantaneous signal to tell the second when to make the count. But there was no effective means of sending such a signal 'at the relevant time': the necessary technology would not be invented for several centuries. Even if we gloss the Fundamental Assumption in the generous way that Dummett recommends, then, it is going to exclude many assertions that we take ourselves to be in a position to make. Its hard-line adherents may swallow that consequence. The rest of us, though, will simply conclude that the Fundamental Assumption is false when applied to disjunctions.

Matters are no better when we turn to (indicative) conditionals. Dummett himself concedes that he cannot defend the Assumption for conditionals with disjunctive consequents (see 1991, p. 273) but in fact the problem conditionals present for it runs far deeper: the

difficulty is that the standard introduction rule, Conditional Proof, is not a plausible codification of the circumstances in which we take ourselves to be entitled to assert English indicative conditionals. If Conditional Proof were the operative introduction rule for the vernacular 'if … then,' a direct ground for asserting a conditional would be a method for transforming any possible ground for the antecedent into a ground for the consequent, but this principle does not get the assertibility conditions of ordinary conditionals right. Variants of Moore's Paradox provide one class of counter-examples. Consider the conjunction 'It is raining but there are no grounds for asserting that it is raining.' It is plausible to hold that there are no possible grounds for asserting this conjunction: any grounds for asserting the first conjunct will falsify the second conjunct. Accordingly, we shall (vacuously) have a method for transforming any possible ground for this conjunction into a ground for asserting a self-evident absurdity, such as $0 = 1$. Given the principle about conditionals, it follows that there is a ground – indeed a direct ground – for asserting 'If it is raining but there are no grounds for asserting that it is raining, then $0 = 1$.' But that conditional does not seem to be one that we shall wish to assert: in entertaining the supposition or hypothesis 'It is raining but there are no grounds for asserting that it is raining' we do not seem to be entertaining an absurdity but something which might well be the case.

The crucial point here is that in a conditional we conditionalize on the *truth* of the antecedent, not on its assertibility. Ironically, in some of his other writings Dummett makes this point very clearly. "In a sentence like 'If you go into that room, you will die before nightfall,'" he remarks, "the event stated in the consequent is predicted on condition of the truth of the antecedent (construed as the future tense proper[10]), not of its justifiability" (1990, p. 193). As a point about the meaning of conditionals in English this is clearly correct, and Dummett goes so far as to conjecture that it is when statements occur as antecedents of conditionals (and in related complex constructions) that we need to draw the distinction between truth and justifiability (1990, p. 193). However that may be, the view that Conditional Proof specifies direct grounds for the assertion of ordinary conditionals is miles from the truth.

One might respond to this by saying that some *other* rule justifies such assertions; on the view we are considering, it will be this other rule which specifies the sense of the conditional. Even if it were possible to formulate an alternative rule, however, that would not help in the present context. For (a) we *do* seem to be prepared to eliminate vernacular conditionals using the rule of *modus ponens* while (b) it is *modus ponens* which stands as the inverse of Conditional Proof (for a proof see, e.g., Negri and von Plato, 2001, p. 8).[11] In other words, whatever exactly they are, the rules which we actually go by in introducing and eliminating vernacular conditionals are not in harmony.

Severe problems also afflict the Fundamental Assumption as it applies to negated statements. According to the Assumption, we shall not be entitled to assert a statement in the form ⌜Not A⌝ unless we could have justified that assertion by applying the introduction rule for 'not.' According to that introduction rule, we may assert ⌜Not A⌝ when we have derived a contradiction from our premises along with the hypothesis A. In many circumstances where we take ourselves to be entitled to assert ⌜Not A⌝, however, it is hard to see what the appropriate premises might be. I look out of the window and see that it is not raining. I am surely entitled to assert 'It is not raining,' but what premises does my observation deliver that would enable me to justify that assertion by applying the rule of 'not'-introduction? In many circumstances of this kind, there is no plausible answer. In looking out of the window, I might see that it is sunny, but being sunny is compatible with rain. The only specification of the content of my experience that is guaranteed to be incompatible

with 'It is raining' is 'It is not raining,' but while I can indeed see that it is not raining, the ensuing belief that it is not raining serves as a *premise* in my reasoning. It is not a *conclusion* that has been reached by applying the rule of 'not'-introduction to some other premises.

In fact, the situation with negation is even worse than that with disjunction and the conditional. In stating the introduction rule for negation, I said that ⌜Not A⌝ may be derived from some premises when the combination of those premises with A yields a contradiction. But what is a contradiction? One answer might be: it is any statement in the form ⌜A and not A⌝ – but we shall know that such a statement is contradictory only if we already know what 'not' means, so we cannot invoke this notion of a contradiction in a rule which purports to give the sense of 'not.' What is worse, if we understand the term 'introduction rule' in the way proposed in §1, it is demonstrable that there is no classically or intuitionistically correct introduction rule for '¬.' More generally, let us follow Humberstone and Makinson in calling a k-place connective **C** *contrarian* if $\mathbf{C}(P_1,\ldots,P_k)$ is valued *False* when all of $P_1,\ldots,P_k$ are valued *True*. (Thus the *falsum* '⊥,' conceived as a zero-place connective, and the unary connective '¬' are both contrarian in this sense.) Then there is no classically or intuitionistically correct introduction rule for any contrarian connective.[12] For let **C** be such a connective and suppose its introduction rule comprises all instances of the scheme

$$< X_1 \Rightarrow A_1,\ldots,X_n \Rightarrow A_n / Y \Rightarrow \mathbf{C}(P_1,\ldots,P_k) >.$$

Since the rule is an introduction rule, it is elementary, so all the formulae in the premise sequents $X_1 \Rightarrow A_1,\ldots, X_n \Rightarrow A_n$ and in the set Y must be sentence letters. But then the rule cannot be classically correct. Consider the substitution instance got by replacing each sentence letter by a classical tautology: under this substitution, each premise sequent becomes classically valid while the conclusion sequent has antecedents that are all true but a false succedent. Since every intuitionistically correct rule is also classically correct, there is no intuitionistically correct introduction rule for a contrarian connective either.

This result may seem bizarre: we teach our logic students sequent rules for '¬,' after all. On reflection, however, it is no surprise that sequent rules *of the form described* cannot characterize the logically relevant meaning of '¬.' Such rules ensure the correctness of certain sequents – that is, they ensure that *if* certain antecedents are true, then so are certain succedents. No collection of such rules can exclude the possibility that all the formulae in the language L are true, but we need to exclude that possibility in order to characterize '¬,' or indeed any contrarian connective. We need to ensure, for example, that ⌜$A \wedge \neg A$⌝ is *not* true.

The operative conception of an introduction rule needs to be liberalized, then, if a contrarian connective is to possess one. From a formal point of view, the simplest and most common liberalization permits a sequent to have a null succedent. We move, in other words, from *set/formula* sequents to *set/formula-or-empty* sequents. Such a sequent is correct if and only if the formula in its succedent is true whenever every formula in its antecedent is true. When the succedent is empty, that is, when there is no formula in it, the sequent will be correct if and only if not every formula in its antecedent is true. The sequent, $Q \Rightarrow \varnothing$, for example, will then be correct if and only if Q is not true. When the logical rules regulate set/formula-or-empty sequents, it is straightforward to give an introduction rule for '¬,' namely, $X \cup \{P_1\} \Rightarrow \varnothing / X \Rightarrow \neg P_1$.[13] Indeed, as Makinson (2014) points out, in such a system we can give an introduction rule for any truth-functional connective apart from '⊥.' We should not expect '⊥' to have an introduction rule.[14] On the theory we are considering, such a rule would specify the canonical conditions for asserting '⊥'; it would be surprising if there were conditions in which a speaker would be entitled to assert a formula which is

understood always to be false. For any connective **C** not equivalent to '⊥,' however, there will be at least one structure v where $v(\mathbf{C}(P_1,\ldots, P_k))$ is true. Where $P_{j_1},\ldots, P_{j_m}$ are those sentence letters evaluated as true under v and $P_{l_1},\ldots, P_{l_n}$ are those evaluated as false there, we have corresponding to v the rule

$$<\varnothing \Rightarrow P_{j_1},\ldots, \varnothing \Rightarrow P_{j_m}, P_{l_1} \Rightarrow \varnothing,\ldots, P_{l_n} \Rightarrow \varnothing / \varnothing \Rightarrow \mathbf{C}(P_1,\ldots, P_k)>.$$

The union of such rules for all v where $v(\mathbf{C}(P_1,\ldots, P_k))$ is true is then the introduction rule for **C**.[15]

Natural as this liberalization is from a formal point of view, it comes at a philosophical price. As remarked at the outset, many adherents of the Harmony Thesis are also adherents of Inferential Role Semantics. As such, they are ambitious to characterize an expression's meaning by the rules that regulate its inferential *use*. The move from set/formula sequents to set/formula-or-empty sequents, however, involves a retreat from direct engagement with the way logical expressions are used in inference. A set/formula sequent represents an actual argument, in which a reasoner passes from a set of premises to a conclusion. Hence the correctness of such a sequent can be related to the intuitive acceptability of the corresponding inferential passage. Where a speaker fails to reach a conclusion, however, we do not have an inference; we merely have a list of statements. Accordingly, we cannot explain the correctness of a set/formula-or-empty sequent directly in terms of the intuitive acceptability of an inference. We shall need instead to give a metalogical account of correctness, such as that in the previous paragraph. This takes us further away from what, for an IRS theorist, is foundational.

There are, to be sure, alternative ways of liberalizing the formal system which cleave more closely to the ideal that its rules should record the way we use connectives. I expounded one of these in my essay '"Yes" and "No."'[16] The operational logical rules given there are 'bilateral' principles which regulate deductive transitions between premises and a conclusion in each of which a yes-no question is followed by one of its expected answers, as in 'Is Fred in Berlin? No. So is it the case that he is either in Paris or is not in Berlin? Yes.' But even if we find a way of remaining faithful to this ideal, the present strategy for justifying the Harmony Thesis has reached a dead end. Dummett conceded that his "examination of the fundamental assumption has left it very shaky" (1991, p. 277), and with this conclusion we can only concur. A theory of the meaning of the connectives which passes muster for 'and,' but which fails for 'or,' 'if … then,' and 'not' – which is committed, indeed, to counting these ubiquitous expressions as meaningless – is not doing at all well.

One might wonder how Dummett felt entitled to pursue his project of justifying the laws of intuitionistic logic, while delegitimating classical logic on the ground of its alleged violations of the Harmony Thesis, when he admitted that the grounds for the Thesis were so shaky. His reason is interesting. The laws of intuitionistic logic, he says, "are not going to be called into question by any uncertainties over the scope or status of the fundamental assumption, precisely because the classical logician will admit that assumption, interpreted in terms of an ideal observer" (1991, p. 279). His thought seems to have been this. At this point in the dialectic, we shall have been so completely persuaded – perhaps by Dummett's own 'manifestation argument,' or his argument about the acquisition of language – that truth needs to be dethroned from its place in the traditional explanation of consequence, that we shall accept the Prawitz–Dummett account of that notion in terms of preservation of direct grounds. It is simply that those people willing to assert (for example) the disjunction 'At the moment when Brutus first stabbed Caesar, there was either an odd or an even number of people in the Agora'

will do so because they are prepared to postulate a God-like ideal observer who was able to make a count of the people in the Agora in Athens at the very moment when the knife went in in Rome. The upshot of our discussion, however, is that this is quite the wrong moral to draw. There is no space to rehearse Dummett's arguments against the intelligibility of a notion of truth that goes beyond the existence of a verification. To put the point at its mildest, though, those arguments are far from conclusive, and our analysis suggests that a real strike against their conclusion is the immense difficulty we shall then face in trying to forge a notion of consequence to replace the familiar one cast in terms of truth-preservation.

More precisely, what we have seen are some of the difficulties in forging an alternative account of consequence that will sustain the Harmony Thesis. At every turn, the traditional account in terms of preservation of truth cries out to be restored. Of course, there is no suggestion that resurrecting the traditional account is going to open any direct path towards justifying classical logic: for one thing, one can adopt the traditional account of consequence without postulating the Principle of Bivalence. But the arguments we have so far considered for imposing a harmony requirement, and for deviating from classical logic because it violates that requirement, lead only into a morass. If this is the best that can be said in favor of the Harmony Thesis, the classical logician has nothing to fear from it.

4 Arguments from the 'Innocence' of Logic

The argument for the Harmony Thesis just analyzed assumes that the introduction rule for a connective specifies its meaning. That assumption is in any case far from compelling. It is more plausible to take ordinary competence with the indicative conditional, for example, to be manifest in applications of its elimination rule – *modus ponens* – than in mastery of whatever rule regulates its introduction.[17] The arguments for Harmony that I consider next do not assume any semantic priority for the introduction rules. Indeed, they do not assume that any one sort of rule – whether it be the introduction rules or the elimination rules – will by itself specify the meanings of the connectives.[18]

The first such argument rests on a premise about the nature of logic. Dummett sometimes writes as though the Inversion Principle follows from a general requirement of harmony that applies between the grounds and consequences of any meaningful statement. Florian Steinberger, *per contra*, argues as follows:

> Whatever misgivings one may have about Dummett's wider project, a strong case can be made for a logic-specific harmony requirement. The reason for this stems from the role logic plays in our assertoric practices. On the use-theoretic view [of meaning], the meanings of non-logical sentences (sentences not containing any logical operators) are thought to be given by their I- and E-principles.[19] Logic, in addition to the direct grounds for assertion given by the appropriate I-principles, offers indirect grounds for asserting non-logical sentences: we may assert a non-logical sentence if it can be correctly deduced from a set of accepted premisses. But for these indirect deductive routes to assertibility to be not only legitimate but to have the unassailable reliability we require of logical inference, our logical modes of inference must respect the conditions under which the (direct) assertion of non-logical sentences is justified. That is, logical inference alone may not license the assertion of non-logical sentences that we should not have been in a position to assert directly (at least in principle). Let us call this the *principle of innocence*: it should not be possible, solely by engaging in deductive logical reasoning, to discover hitherto unknown (atomic) truths that we would have been incapable of

> discovering independently of logic…. How can we make sure that innocence obtains? This is where harmony comes in. The primary purpose of harmony is to secure the innocence of logic. (Steinberger, 2011, pp. 619–620)

Steinberger further contends that harmony is the best way – perhaps the only way – of securing innocence:

> A moment's reflection reveals not only that harmony is an adequate measure, but that it seems entirely natural that any measure designed to guarantee the holding of the requirement of innocence should take the form of a harmony requirement. After all, our aim is to ensure that the meanings of the logical constants are fixed in such a way as not to perturb the non-logical regions of language. The best way to do this (at a local level) is by requiring that the introduction and elimination rules that govern the meanings of logical constants be exactly commensurate in strength. Why? Well, because when such an equilibrium between I-rules and E-rules obtains, we can rest assured that our deductive practices will not, as it were, create novel grounds for asserting non-logical sentences (as in the case, for example, of [Prior's invented connective] *tonk*). The requirement of harmony thus seems to be an eminently reasonable and natural safeguard for the principle of innocence. (Steinberger, 2011, p. 620)

Steinberger spells out as follows the equilibrium he has in mind: "nothing more and nothing less may be deduced from an assertion of $A\$B$ via \$-E than can already be deduced from the premisses of the corresponding I-rules. Put another way, … the E-rules ought to exploit *all* and *only* the inferential powers that the I-rules have bestowed upon it" (Steinberger, 2011, p. 620). His requirement of equilibrium, then, demands the satisfaction of Negri and von Plato's Inversion Principle, and something more besides. As we saw in §1, their Inversion Principle is satisfied when the standard introduction rule for '$\vee$' is paired with its quantum-logical elimination rule, but Steinberger insists that that elimination rule fails to exploit *all* the inferential power bestowed by the introduction rule (see his discussion of 'E-weak disharmony,' 2011, p. 621). If it works, then, Steinberger's argument justifies a form of the Harmony Thesis that is even more exacting (as far as the logical connectives are concerned) than that proposed by Prawitz and Dummett.

Does his argument work, though? There are strong reasons to doubt it.

First, the principle of innocence is far less compelling than Steinberger supposes. Since Mill's *A System of Logic*, with its notorious claim that "nothing ever was, or can be, proved by syllogism which was not known, or assumed to be known, before" (Mill, 1891, II iii 1), a central problem in the philosophy of logic has been to reconcile the conclusiveness of correct deduction with its ability to expand our knowledge. Part of the explanation of how deduction generates new knowledge is that premises founded on different sources of knowledge can entail a conclusion that no source founds by itself. A trusty informant tells me that John is either in the common room or in the library; I see that he is not in the common room; I deduce that he is in the library. I know the first premise through testimony and I know the second as result of observation. But whilst I come to know the conclusion, my knowledge of it does not stem from either testimony or observation alone: I was not told that John is in the library, nor did I see him there. Of course, this case is not itself a counter-example to Steinberger's principle of innocence. Although I did not in fact see John in the library, in principle I could have done. In our ordinary deductive practice,

however, we are fully prepared to splice together different sources of knowledge to deduce conclusions that could not be founded on any 'direct' evidence, even in principle. Suppose I know – through astronomical theory, and appropriate observations – that a body *B* is either in region *R* of the Andromeda Galaxy or is in a black hole. Suppose I make some further observations, and come to know that *B* is not in region *R*. I may then deduce that *B* is in a black hole. It is (we may assume) impossible even in principle to discover by direct observation whether a body is in a black hole. For all that, this second deduction appears to be just as cogent as the first. In each case, the deduction yields knowledge of its conclusion, even though in the second case such knowledge could not have been attained directly, even in principle. *Contra* Steinberger's principle of innocence, then, by engaging in deduction we can discover hitherto unknown atomic truths which we would have been incapable of discovering without logic. The principle of innocence is far from innocent. Were it accepted, it would seriously restrict the use we actually make of deductive logic in enlarging our knowledge.

Second, even if we grant the principle, it may be secured by a weaker requirement than that of equilibrium between introduction and elimination rules. As Steinberger acknowledges, innocence will be secured if the non-logical regions of language are unperturbed by the logical rules – that is, if those rules create no novel grounds for asserting non-logical (i.e., atomic) sentences. This condition will be met if the logical rules *en bloc* create no such novel grounds – a 'global' condition in his terms. To ensure innocence, then, we need not descend to the 'local' level and require the introduction and elimination rules of each individual connective to be in equilibrium.

There is, in fact, a natural way of making the global condition more precise. The direct grounds for asserting non-logical formulae will induce a consequence relation R^- on the sublanguage L^- that comprises only such formulae. Innocence will be secured if the expanded consequence relation *R* that is induced on the full language *L* when the logical rules are added is a *conservative extension* of R^-. That is, *R* as restricted to L^- does not extend R^-. Steinberger is well aware that this global condition may be satisfied even when the introduction and elimination rules of a certain connective are not in equilibrium (2011, pp. 625 and 634–638). The problem is that his principle of innocence only sustains the global condition. The conservative extension requirement is enough to ensure that the 'meanings' of atomic formulae – or better: the consequential relations between them – are left unperturbed. It also excludes Prior's rogue connective 'tonk,' whose introduction rule is $< P_1 / P_1$ tonk $P_2 >$ and whose elimination rule is $< P_1$ tonk $P_2 / P_2 >$ (Prior, 1960). 'Tonk' is indeed a runabout inference ticket, which licenses the move from one formula to any other, so its rules will violate conservativeness unless the pre-logical consequence relation R^- is already total (see Belnap, 1962).

Robert Brandom's conception of logic is similar to Steinberger's, but he is more circumspect about its implications for harmony (Brandom, 1994; 2000). On Brandom's view, what characterizes the logical notions is their role in 'making explicit' the relations between non-logical sentences that are traced out in material inferences and in recognitions of incompatibility. A good material inference takes a thinker from 'Edinburgh is north of London' to 'London is south of Edinburgh'; we may express our acceptance of that inference by asserting the conditional 'If Edinburgh is north of London, then London is south of Edinburgh.' Similarly, we express our recognition of the incompatibility between the table's being red all over and its being green all over by saying, 'If the table is red all over,

then it is not green all over.' What Brandom takes to follow from this doctrine is, simply, the conservative extension requirement:

> Unless the introduction and elimination rules are inferentially conservative, the introduction of the new vocabulary licenses new material inferences, and so alters the contents associated with the old vocabulary. So if logical vocabulary is to play its distinctive expressive role of making explicit the original material inferences, and so conceptual contents expressed by the old vocabulary, it must be a criterion of adequacy for introducing logical vocabulary that no new inferences involving the old vocabulary be made appropriate thereby. (Brandom, 2000, pp. 68–69; see Brandom, 1994, pp. 123–130 for a fuller exposition of the same argument)

Brandom is right, I think, to claim that his expressivist account of logic demands the conservative extension requirement. The important point for present purposes, however, is that it *only* demands that: conservative extension may be satisfied even if the rules for the connectives do not satisfy the Principle of Inversion, that is, even if the Harmony Thesis is false.[20]

This comes out clearly, indeed, in the case of the classical propositional calculus. As noted earlier, the introduction rule for negation is *Simple Reductio*: $X \cup \{P_1\} \Rightarrow \varnothing / X \Rightarrow \neg P_1$. The elimination rule which is in harmony with this is *Ex Contradictione Quodlibet*: $\{P_1, \neg P_1\} \Rightarrow P_2$. While these two rules together characterize the intuitionistic logic of negation, its classical logic demands a further principle. There are many additional principles which will do. For definiteness, let us add the rule form of Excluded Middle,

$$EM: \quad X \cup \{A\} \Rightarrow B,\ Y \cup \{\neg A\} \Rightarrow B / X \cup Y \Rightarrow B.$$

(Adding assumptions to a sequent is often called 'thinning,' so Harold Hodes aptly calls *EM* a 'thickening' rule: it allows the deduction of a sequent from other sequents with the same succedent whose antecedents include formulae which do not appear in the antecedent of the conclusion (Hodes, 2004, p. 148)). In the resulting system, the Harmony Thesis is violated: the logical behavior of '¬' is not regulated *only* by a pair of harmonious introduction and elimination rules. But the classical consequence relation conservatively extends whatever pre-logical consequence relation obtains among the non-logical formulae: where $P_1, \ldots, P_n$ and Q are atoms, there is a classically admissible truth-value assignment which assigns *True* to all of $P_1, \ldots, P_n$ and False to Q, so if Q is a consequence of $P_1, \ldots, P_n$, that must be because the pre-logical consequence relation determines it as such.[21]

5 Tennant's Argument for Harmony

Neil Tennant is an adherent of the Harmony Thesis who distinguishes sharply between harmony proper and the conservative extension requirement.[22] He also holds that the introduction rule and elimination rule for a connective *jointly* determine its sense, so that the Thesis cannot be justified by requiring the rules of one sort to keep faith with the meanings already laid down by rules of the other sort.[23] Rather, he holds, its justification arises from a requirement of coherence between the introduction and elimination rules for a given connective. As Prior's 'tonk' shows, not every pair of introduction and elimination rules succeeds in endowing the connective it purports to characterize with a sense. It is by spelling out the requirements for coherence that Tennant aims to justify the Thesis.[24]

The precise form of harmony that Tennant defends is subtly different from that in Negri and von Plato. To state it accurately we need some terminology. Let us say that a formula is a *maximally strong F* if it is *F* and entails any formula that is *F*; and let us say that a formula is a *maximally weak F* if it is *F* and is entailed by any formula that is *F*. Tennant's First Principle of Harmony may then be stated as follows. A formula whose main connective is **C** is to be

(a) a maximally strong statement that can stand as conclusion of the introduction rule for **C**, given the elimination rule for **C**; and
(b) a maximally weak statement that can stand as major premise of the elimination rule for **C**, given the introduction rule for **C**.

We may illustrate this First Principle with the case of '$\vee$.' To show part (a) for this connective, let *X* be any formula that can stand as the conclusion of $\vee$-introduction, with *A* and *B* as premises. We then have that *A* entails *X* and *B* entails *X*. By $\vee$-elimination, it follows that $\ulcorner A \vee B \urcorner$ entails *X*, showing that $\ulcorner A \vee B \urcorner$ is a maximally strong statement that can stand as conclusion of $\vee$-introduction. To show part (b), let *Y* be any formula that can stand as the major premise of $\vee$-elimination. Then, whenever *A* entails *C* and *B* entails *C*, *Y* entails *C*. By $\vee$-introduction, *A* entails $\ulcorner A \vee B \urcorner$, as does *B*, so *Y* entails $\ulcorner A \vee B \urcorner$. Thus $\ulcorner A \vee B \urcorner$ is a maximally weak statement that can stand as major premise of $\vee$-elimination.

As this demonstration shows, Tennant's First Principle is satisfied whether the $\vee$-elimination rule has its usual form, in which the use of side premises is permitted, or takes the restricted form it has in quantum logic, in which *C* may be inferred from $\ulcorner A \vee B \urcorner$ only if it follows from *A* alone and from *B* alone. The First Principle, then, fails to distinguish between the two forms of the rule. For this reason, Tennant also lays down a Second Principle. When a pair of introduction and elimination rules **CI** and **CE** for a connective **C** meets conditions (a) and (b), let us say that the pair is in harmony (with a small 'h'). We further say that the pair is in Harmony (with a capital 'H') if **CE** is the strongest elimination rule with which **CI** is in harmony and **CI** is the strongest introduction rule with which **CE** is in harmony. Tennant's Second Principle requires the rules for a meaningful connective to be in Harmony. The form of $\vee$-elimination which permits side premises is stronger than the form which does not: it allows us to derive more conclusions from a given disjunction. It is the unrestricted form of the elimination rule, then, which is in Harmony with the rule of $\vee$-introduction, so the restricted form falls foul of Tennant's Second Principle. It is good to have a criterion which improves on Negri and von Plato's Inversion Principle in excluding the restricted form of $\vee$-elimination. We shall, however, need a justification for requiring rules to be in Harmony as well as harmony.

Tennant contends that satisfaction of both his Principles of Harmony is 'a *conditio sine qua non* of' rules specifying or constituting a coherent meaning for the connective in question (1987, p. 94). He further claims that this condition has revisionary implications for logic. "The correct consequence relation, insofar as it should arise solely from the meanings of the logical constants, is, naturally, the least relation with respect to which the Harmony of the rules governing those constants can be sustained" (1987, p. 97). The least such relation, Tennant thinks, is that characterized by the system he calls intuitionistic relevant logic. "I intend thereby to reveal as unjustifiable excrescences the extra ingredients in the consequence relation of classical logic that have earned the generic labels (a) the fallacies of relevance, and (b) the classical laws of negation" (1987, p. 97). We need, then, to consider the arguments Tennant advances for two theses. The first thesis is his claim that satisfaction of the two Principles of Harmony is a necessary condition for a connective to possess a coherent meaning.

The second is the claim that any logical principles that go beyond a Harmonious pair of introduction and elimination rules are 'unjustifiable excrescences.' I shall contend that neither of these theses is well supported.[25]

How does Tennant argue for the first thesis? The precise course of his reasoning is somewhat hard to follow, but we are told that "the requirement for harmony emerges clearly if one follows a philosophical method that has the appearance of empirical speculation about the origins of language, but is actually designed to focus on constitutive features of meaning. This is the method of enquiring after the *aetiology of entrenchment* of expressions in a language and of conventions governing their use" (1987, p. 77). The general idea is that we shall be unable to explain how the logical connectives could have become entrenched in a language – that is to say, how they could have acquired a stable meaning – unless their introduction and elimination rules are in Harmony. The claim that Harmony is a *conditio sine qua non* for such rules to constitute or specify a connective's meaning duly comes at the end of a long passage describing how meanings for the connectives might have become entrenched.

What is Tennant's account of entrenchment? It certainly has the appearance of empirical speculation about the origins of language. We are asked to imagine a community of speakers who start off using only atomic statements; Tennant then asks how connectives could be added – one at a time – to their dialect. He suggests that we would be unable to understand how this could happen unless the rules governing those connectives satisfy his two Principles of Harmony.

This account exemplifies a genre which one might call the *Just So Story*. We find it hard to imagine how a meaningful connective could have been added to a language unless certain conditions are met. So we take those conditions to be necessary for the connectives to have a meaning. Of course, my name for the genre carries a warning. Kipling's account of how the elephant got its trunk does have a certain explanatory charm. Few people today, though, would regard it as even a remote approximation to the truth. So if we are, O Best Beloved, to venture forth to the philosophical tributary of the great grey-green, greasy Limpopo River, all set about with normalized proof trees, we shall need to take care. We shall need to make sure that if a condition is imposed on the connectives, the condition really is necessary for them to have a meaning and does not simply express a philosopher's preconceptions about how language ought to work. If we read Tennant's account with that warning in mind, we shall find his story even less persuasive than Kipling's.

The root of the problem is that Tennant's account of how the connectives get entrenched does not explain how they come to have their actual meanings. The difficulty comes out clearly in the case of negation – a case which is of course central to the choice between classical and intuitionistic logic. Our signs for negation, Tennant hypothesizes, originate in the need one speaker may have to contradict or challenge an atomic assertion by another: "dialogue, not monologue is where negation first flourishes" (1987, p. 83). Let us accept this for the sake of argument. "The challenger," he goes on, "must have information to the contrary, rather than be merely playing the role of the *uninformed* doubter" (1987, p. 84). Let us accept this too. Tennant further contends that a speaker who challenges A by saying $\ulcorner$ Not A $\urcorner$ is "saying something *about the same subject matter* as A" (1987, p. 84, emphasis in the original). If a speaker who says $\ulcorner$ Not A $\urcorner$ were merely doubting "the existence of a warrant for [A], then the challenge would be self-warranting, for nothing could serve as better evidence for such a claim than its own making" (1987, p. 84). Again, this seems right. Tennant infers from this that the sort of challenge to A that is expressed by $\ulcorner$ Not A $\urcorner$ "must be conceived of as possessing warrants that are as open to independent public assessment

as are the warrants of the assertions challenged" (1987, p. 84). We may accept this too. "Denial of *A*," he concludes, "has the force 'I have good reason to believe that there is no warrant for *A*' rather than the weaker 'I have no reason to believe (apart from your asserting it) that you have any warrant for *A*.' Denial … carries with it no in-built guarantee of excluded middle" (1987, p. 85).

That final conclusion, though, does not follow from the considerations that are adduced to support it, and in any case Tennant seriously misrepresents the way ordinary speakers actually use signs for negation. Of course Tennant is right to claim that someone who says ⌜ Not *A* ⌝ is saying more than 'I have no reason to believe that you have any warrant for *A*.' As Heyting pointed out long ago, if this were the right account of the meaning of 'not,' then someone who said 'Not every even number greater than two is the sum of two primes' would be making an autobiographical statement, not a mathematical one. But Tennant's account equally misrepresents the content of that negated claim. On his view, someone who makes the claim is saying 'I have good reason to believe that there is no warrant for the claim that every even number greater than two is the sum of two primes.' Now in certain circumstances that might be a perfectly sensible thing to say, and if one understands negation in this way, then the law of excluded middle will indeed fail to be valid. It is not, however, the way most of us understand negation. On Tennant's account, it would be correct to say 'Not every even number greater than two is the sum of two primes' if the Goldbach Conjecture were unprovable. For most of us, though, it would be correct to say as much only if the Conjecture were false – that is, only if some even number greater than two were not the sum of two primes.

It may be replied that to object in this way is to fail to take seriously the possibility that classical logic might need to be revised. Not so: the objection is simply to Tennant's argument for revising it. It is, we are told, impossible to understand how the use of 'not' could have become entrenched unless it originated in the way Tennant describes. But the story he tells fails to explain the patterns of use which have actually become entrenched. In this respect, his Just So Story is less persuasive than Kipling's, for Kipling was at least offering an explanation for something that is actually the case. Elephants, after all, really do have trunks.

So much for Tennant's first thesis. What about his claim that any logical principles that go beyond a Harmonious pair of introduction and elimination rules are 'unjustifiable excrescences'? As far as I can discern, the only argument he gives for this second thesis is in a parenthesis: "The correct consequence relation, insofar as it should arise solely from the meanings of the logical constants, is, naturally, the least relation with respect to which the Harmony of the rules governing those constants can be sustained" (1987, p. 97). That 'insofar as' clause is doing all the work. Tennant seems to take it to be obvious that the logical laws regulating a connective will arise solely from its meaning, but he gives no argument for this claim, which is in truth very far from obvious. Certainly, it is not obvious that only introduction and elimination rules may regulate a connective's logical behavior. A classical logician might hold the position sketched at the end of §4, whereby the introduction and elimination rules for negation are the intuitionistic ones – namely, the rules of *Simple Reductio* and *Ex Contradictione Quodlibet* – but where an additional rule concerning negation – the thickening rule *EM* – is nevertheless valid.[26] There is no question of trying to justify *EM* by way of harmony considerations: it has the form neither of an introduction rule nor of an elimination rule. However, in the absence of any argument for the claim that the only valid principles that concern a connective are a Harmonious pair of such rules, there is no basis for Tennant's claim that *EM* is an 'unjustifiable excrescence.'

Tennant may protest that the case of 'tonk' shows that there must be some constraints on the introduction and elimination rules for a meaningful connective. Many people believe that those constraints amount to Harmony. Adding extra logical rules for a connective threatens to destabilize the equilibrium that Harmony guarantees, and thereby deprive the connective in question of a coherent sense. But there is a far better explanation of why 'tonk' is meaningless than that it violates Harmony. It is not meaningful, because a formula whose main connective it is does not *say* anything; such a formula does not say anything because it does not have truth-conditions. Thus consider the formula '2 is prime tonk 4 is prime.' This formula follows by 'tonk'-introduction from '2 is prime,' which is true, so it must be itself true. Yet '4 is prime,' which is not true, follows by 'tonk'-elimination from it, so the formula cannot be true. No coherent truth-condition can be assigned, then, to '2 is prime tonk 4 is prime,' and since both components do have truth-conditions, the culprit is clearly 'tonk.' As an explanation of why 'tonk' is meaningless, this explanation is superior to Belnap's, according to which 'tonk' is defective because it non-conservatively extends the pre-existing consequence relation. We shall sometimes want to do that, as when we add a truth-predicate to a mathematical theory (see n. 21 above), but we shall never want a declarative formula to lack truth-conditions. If a formula succeeds in saying something, it will have a truth-condition, *viz*., the condition that is satisfied if, and only if, things are as the formula says they are. So the only declarative formulae that lack truth-conditions are those that fail to say anything.[27]

6 Harmony and Inferential Role Semantics

Our examination of three prominent arguments for the Harmony Thesis has left it without any justification. Supposing it is false, does that threaten IRS? I think not. Our discussion of the Dummett–Prawitz argument for Harmony revealed the huge difficulties that confront the project of trying to explicate the notions of consequence and validity *directly* in terms of the rules which, for the IRS theorist, constitute the meanings of the connectives. But the IRS theorist is free to take an indirect approach. He might take the rules that characterize a connective's inferential role as specifying its sense, but allow that it also has a reference, or a semantic value. This semantic value will be the contribution the connective makes to the truth-conditions of a formula in which it occurs. Once we have a specification of truth-conditions for formulae of the relevant language, we can apply the traditional account of consequence in terms of the preservation (or necessary preservation) of truth.[28]

This oblique approach plainly requires an account of *how* the inferential roles determine semantic values – in Fregean terms, how sense determines reference. That is, it requires what Christopher Peacocke calls a 'determination theory.' In his paper "Understanding logical constants: a realist's account" (1987), Peacocke begins to develop such a theory for the connectives, and Hodes (2004) has pursued the matter further. The best hope of an IRS theory of meaning lies, I think, with this approach, and the determination theory goes more smoothly if the inferential roles played by the connectives are characterized by the 'bilateral' rules mentioned at n. 16 above, rather than the more familiar 'unilateral' rules. The kernel of any determination theory for the connectives will be the principle that the rules the reasoner goes by (or ought to go by) must preserve the correctness of sequents. For unilateral sequents, correctness is in turn a matter of preserving truth. Even given Bivalence, however, this constraint on the classical sequent rules fails to ensure that ⌜Not A⌝ is true whenever

A is false (see Peacocke, 1987, p. 164, and Hodes, 2004, p. 162). By contrast, that fact about the semantic value of 'not' may be 'read off' the intuitive correctness of the bilateral sequent rule exemplified by 'Is Fred at home? No. So is it the case that Fred is not at home? Yes.'

Whether a fully satisfactory determination theory can be given for the connectives is an open question – one of the most interesting and pressing in the philosophy of logic and language. The verdict on the immediate issue, though, is clear. Some people like Górecki's Third Symphony but few would say that it is a patch on Beethoven's. One reason is that Beethoven knew better when to leaven harmony with dissonance. As in music, so in logic: there is no universal requirement of harmony.

Notes

1 This chapter derives from an address delivered to a conference on Logic and Inference held at the University of London on March 20, 2015. I am much indebted to the organizers, Julien Murzi and Florian Steinberger, and to those who participated in the discussion: Sinan Dogramaci, Gilbert Harman, Gail Leckie, David Makinson, and Joshua Schechter. I also thank the editors of this volume for helpful comments on a draft.

2 On my account, then, introduction and elimination rules are rules in a sequent calculus. Some of the writings to be examined below take harmony to be a relation between rules in natural-deduction formalizations of logic. In a rigorous treatment of this topic, however, it is best to work in a sequent framework, where the assumptions on which a conclusion depends are explicitly represented. The philosophical arguments for harmony proposed by those who prefer natural-deduction formalizations transpose to the sequent framework.

3 For these definitions, cf. Humberstone and Makinson (2012, §2). As they remark (§2, n. 5), a rule which is elementary in the present sense will be both 'pure' and 'simple' in the terminology of Dummett (1991).

4 In the first edition of *Elements of Intuitionism* (1977, pp. 394–395), Dummett argued that the theory could be made compositional, all the same. For skepticism about his proposed way of achieving this, see Prawitz (1987, esp. pp. 156–163) and Pagin (2009, esp. pp. 724–734). Dummett entirely rewrote this passage for the second edition of *Elements*, and there concluded that the form of compositionality that could be justified was only "a very thin one" (2000, p. 274).

5 On the history of inversion principles, with references to Lorenzen (1950; 1955) and Schroeder-Heister (1984) as well as to Gentzen (1935) and Prawitz (1965), see Moriconi and Tesconi (2008).

6 Thereby gratifying a *desideratum* of Gentzen's: "By making these ideas more precise it should be possible to display the *E*-inferences [i.e., the elimination rules] as unique functions [*eindeutige Funktionen*] of their corresponding *I*-inferences [introduction rules], on the basis of certain requirements" (Gentzen, 1935, p. 189/1969, p. 81).

7 The same problem attends Stephen Read's requirement of 'general-elimination harmony.' See Read (2010, p. 566).

8 As Negri and von Plato recognize, their Inversion Principle yields more general forms of $\wedge$-elimination and of $\rightarrow$-elimination than one usually finds in the textbooks (see 2001, pp. 6–7 and 8–9). I do not object to this aspect of their theory, which might well be a bonus rather than a drawback. However, the inability to justify the unrestricted form of $\vee$-elimination is a difficulty.

9 Kripke presented this case in lectures which remain unpublished, but Lewis (1997) contains a brief account of it. Kripke has long been on record as an opponent of counterfactual and dispositional accounts of color; see n. 71 to *Naming and Necessity* (Kripke, 1980, p. 140).

10 Dummett contrasts the 'proper' or 'genuine' future tense with "the future tense used to express present tendencies." "The latter occurs, e.g., in an announcement of the form 'The wedding announced between *A* and *B* will not now take place.' Such an announcement cancels, but does

not falsify, the earlier announcement, and is not itself falsified if the couple later make it up and get married after all; if this were not so, the 'now' would be superfluous" (Dummett, 1972, p. 21).

11 Vann McGee (1985) presents a case where, he thinks, we are not prepared to use *modus ponens* in drawing consequences from an indicative conditional; but see Rumfitt (2013, pp. 176–178 and 185–186) for an alternative analysis of his case.

12 This result is the first 'Observation' in §3 of Humberstone and Makinson (2012).

13 In *The Logical Basis of Metaphysics*, Dummett adopts a very different approach to the problem of finding an introduction rule for negation. He works in a language with an infinite collection Q_1, Q_2, … of atomic formulae. In our notation, his introduction rule for '¬' is the infinitary rule whose underlying tuple is $< P \Rightarrow Q_1,\ P \Rightarrow Q_2,\ \ldots / \varnothing \Rightarrow \neg P >$ (Dummett, 1991, p. 295). He also proposes a cognate introduction rule for '⊥': $< / Q_1, Q_2, \ldots \Rightarrow \bot >$. In the event that the atomic formulae of the language form a consistent set, his introduction rule for '¬' allows A and $\ulcorner \neg A \urcorner$ both to be true. Similarly, his introduction rule for '⊥' allows '⊥' to be true in those circumstances. These features are surely weaknesses in his theory. Since Dummett was not a dialetheist, an account which leaves it an open matter whether there can be true contradictions must be failing to characterize logically relevant aspects of the meaning of the negation sign. Similarly, an account which leaves open the possibility that the *falsum* might be true is not capturing the intended sense of '⊥.' Dummett may be right to say that in his system "no logical laws could be framed that would entail" that not every atomic sentence can be true (1991, p. 295), but that is a limitation of his system. In a system of set/formula-or-empty sequents, the rule $< / A, \neg A \Rightarrow \varnothing >$ entails that A and $\ulcorner \neg A \urcorner$ cannot both be true, and the infinitary rule $< / Q_1, Q_2, \ldots \Rightarrow \varnothing >$ excludes the possibility that $Q_1, Q_2, \ldots$ form a consistent set.

14 It has, of course, an elimination rule: $< / \bot \Rightarrow \varnothing >$.

15 We may liberalize introduction and elimination rules to those governing set/formula-or-empty sequents while retaining the requirement that such rules must be elementary. If we do this, we shall exclude the introduction and elimination rules that Stephen Read proposes for his paradoxical zero-place connective 'bullet,' a proof-conditional Liar sentence (Read, 2000, pp. 140–142). Those who regard the bullet as meaningless will wish to retain the requirement of elementariness.

16 Rumfitt (2000). When I wrote that paper, I still thought there might be something in the Harmony Thesis, so I was concerned to show how the operational rules of my system conformed to an analogue of the harmony requirement. I no longer see any grounds for requiring such conformity.

17 See again n. 11 above on purported counter-examples to *modus ponens*.

18 Recognizing the difficulties confronting his Fundamental Assumption, Dummett briefly canvassed an alternative theory whereby every connective's meaning is given by its elimination rule. On this view, justifying the Harmony Thesis "will depend upon an inverse fundamental assumption, namely, that any consequence of a given statement can be derived by means of an argument beginning with an application of one of the elimination rules governing the principal operator of that statement, in which the statement figures as the major premiss. This assumption is open to fewer intuitive objections than the fundamental assumption on which our original justification procedure rested. It is more plausible that we derive simpler consequences from complex statements only when those consequences follow logically than that we assert such statements only when they follow logically from simpler statements we have previously accepted" (Dummett, 1991, p. 281).

Dummett's account of this alternative 'pragmatist' theory is sketchy, although Prawitz (2007), Queiroz (2008), and Litland (forthcoming) have developed it further. In particular, Litland (forthcoming, §4) corrects various mistakes in Dummett's sketch, and shows that a cleaned-up Inverse Assumption justifies precisely the intuitionistic introduction rules for the connectives, given the intuitionistic elimination rules for them. It is good to know where this approach leads. In later writings, however, Dummett came to doubt if the sort of pragmatist theory of meaning that the Inverse Fundamental Assumption requires could be coherently elaborated (see especially Dummett, 2007). In Rumfitt (2017), I identify a number of foundational problems that pragmatist theories of meaning must face, and criticize extant attempts to solve them.

19 In Steinberger's terminology, the 'I-principles' pertaining to a sentence *A* state the conditions in which a speaker of the relevant language is entitled to assert *A*. The corresponding 'E-principles' state what a speaker who asserts *A* is thereby entitled to do. (See 2011, p. 618.)

20 Peregrin (2008) argues that intuitionistic logic is the strongest logic that makes inferences explicit. He reaches this conclusion, however, by importing a number of contentious assumptions into the explanation of what it is to make an inference explicit.

21 If the introduction and elimination rules of a new connective are in harmony, will the resulting system conservatively extend the pre-existing consequence relation? Prawitz (1994, p. 374) argued not: the natural introduction and elimination rules for the truth-predicate are in harmony, but the result of adding a truth-predicate to Peano Arithmetic is not a conservative extension of it. See, however, Hodes (2004, pp. 148–150) and Steinberger (2011, pp. 635–637) for reasons to doubt whether the scope of introduction and elimination rules should be extended to encompass predicates as well as operators.

22 See especially Tennant (1987, ch. 10), which patiently untangles passages in Dummett's early writings on the topic (1975a; 1975b) that mix up the two requirements.

23 At least, he does in his book *Anti-Realism and Logic* (Tennant, 1987). In *The Taming of the True*, he holds that the introduction rules give the meanings of the connectives as they are used in *a priori* science whereas the elimination rules give their meanings as they appear in empirical discourse. Harmony is then needed to ensure that there is no equivocation between the two sorts of occurrence (Tennant 1997, p. 23). Unfortunately, I lack the space to analyze this argument here.

24 See especially p. 94: "There is another kind of equilibrium, which would be of interest even to one who refuses to acknowledge the asymmetric division of rules into those that are constitutive and those that are merely explicative of meaning. This way is to regard the rules of introduction and elimination as equally involved in specifying or constituting meaning, but to demand harmony as a *conditio sine qua non* of their doing so. The thought would be that not just any set of rules will do in order to confer determinate meaning on a logical operator."

25 It is Tennant's second thesis that justifies his claim that the correct laws of logic are confined to the rules of intuitionistic *relevant* logic. This logic yields the *least* consequence relation that satisfies his two Principles of Harmony. Litland (forthcoming, part II) shows in effect that full intuitionistic logic is the strongest logic that satisfies the two Principles.

26 This is, indeed, Hodes's position in his (2004). He holds that only introduction and elimination rules can constitute the sense of a connective (p. 147), and requires that the elimination rule should be the maximum inverter of the introduction rule and that the introduction rule should be the maximum invertee of the elimination rule (p. 156). (This amounts to Tennant's requirement of Harmony.) Hodes defines the 'basic logic' of a language to be that comprising only the sense-constituting rules for the connectives (p. 151). Given his requirement of Harmony, he takes the basic logic for English to be first-order intuitionistic logic (p. 151). However, he allows that other sorts of rule, including *EM*, are fully justified (p. 154), so that the 'total logic' for ordinary mathematical English is classical.

Hodes advances no argument for the Harmony requirement: he simply presents it as a conjecture whose implications are worth tracing out. Given that he allows the legitimacy of *EM*, though, his acceptance of the Harmony Thesis is in any case somewhat half-hearted. On his view, *EM* is a legitimate part of our inferential practice with negation. From an IRS perspective, then, it *is* part of the meaning of 'not.' I do not see the point of saying that, because *EM* is neither an introduction nor an elimination rule, it is not part of the *sense* of that word.

27 This account of what is wrong with 'tonk' is essentially that proposed by J. T. Stevenson in his reply to Prior (Stevenson, 1961). Stevenson's reply was rather eclipsed by Belnap's, which appeared the following year and started the harmony hare running. Brilliant as Belnap's paper is, I think it was Stevenson who gave the better explanation of why 'tonk' fails to have a sense.

28 In the Dewey Lectures which he delivered at Columbia University in 2002 (published as Dummett, 2006), Dummett retreated to this position. "The proponent of a truth-conditional

theory of meaning," he wrote, "must argue that [the] use [of sentences] cannot be described without appeal to the conditions for the truth of statements … To an important degree, such an argument would be correct" (Dummett, 2006, p. 29). Truth is 'indispensable' in describing how sentences are used because "a salient part of using a language is to give arguments in support of some conclusion," so that a full description of their use "needs a notion of truth, as that which is guaranteed to be transmitted from premisses to conclusion of a deductively valid argument" (2006, pp. 29, 31, 32).

Meaning and Privacy

EDWARD CRAIG

1 Introduction: The Two Questions and their Consequences

It has been widely held that certain states of sentient creatures are private, in the technical sense that their nature cannot be known by anyone other than the subject who experiences them. For instance, the phenomenal quality of perceptual states has often been seen in this light. "I know you call that color by the same name, but I can't know whether you see it in the same way as I do" is a position familiar to most students of philosophy, both amateur and professional. Involved, clearly, are issues in both the philosophy of mind and epistemology, but it is not the purpose of this chapter to go into these in depth; for the moment the reader should assume – or at least be prepared to entertain the hypothesis – that there are indeed states which are private in the sense defined. We may call them epistemically private items (EPI).

A general question arises about the role, if any, of such EPI in the meaning of language. A highly influential tradition makes the meaning of a word depend on the nature of the "idea" associated with it, whilst treating ideas as items before the consciousness of speakers and their hearers, hence as strong candidates for epistemic privacy. Much recent argument, on the other hand, denies that the epistemically private can have any such part to play, and that it is precisely the fact of its privacy that rules it out of semantics.

The debate thus broadly characterized focuses not on one question, however, but two, close enough to be conflated by the unwary, yet quite different enough for all hope of clarity to be gone if they are not carefully distinguished. One concerns the semantics of the "public" language, the one in which we communicate, or apparently succeed in communicating, with each other; the other is the notorious question about the possibility of a "private" language, that is to say a language used by a person for the sole purpose of communicating with their own (later) self, and in principle unusable for communication with anybody else. We shall have to ask:

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

(1) whether the nature of our EPI affects, or can affect, the semantics of a natural language used for interpersonal communication
(2) whether there can be a private language, in which a person records facts about their EPI for their own later information.

The content of the first of these questions is easy enough to grasp, even if the arguments that are brought to bear on it may be less so. But a "private" language sounds like a highly artificial construction, and a little time must therefore be spent inquiring just what such a language is supposed to be.

The *locus classicus* is Ludwig Wittgenstein's *Philosophical Investigations*, §243:

> The words of this language are to refer to what can only be known to the person speaking: to his immediate private sensations. So another person cannot understand the language.

As an introduction to the concept of a private language this passage is not without its difficulties. The first sentence appears to commit itself to at least a limited skepticism about the contents of other minds, though it is probably better read as a definition of the concept of privacy, with the plausible assumption added that if there is anything private in this sense, the phenomenal quality of states of consciousness will be so. The second sentence implicitly brings in another assumption: that A can understand B only if he *knows* the nature of the objects B is referring to. We shall later see that this is open to question, with the result that it may make a difference whether we take "private language" to be defined by the first sentence of the quotation or the second. By no means all the literature on the topic pays due attention to this possibility.

Since the assimilation of Wittgenstein's *Philosophical Investigations* (1953) it has been common, indeed almost standard, to answer both questions in the negative: EPI have no role to play in the semantics of any public language; and there can be no such thing as a private language. Moritz Schlick, in a series of lectures delivered in London in 1932, in effect had made both these claims. More recently Michael Dummett (Dummett, 1973) has offered reasons in favor of the negative thesis about EPI and public language; the extent to which these arguments are new, and the extent to which they reformulate or adapt points from earlier literature, will be considered in what follows.

The two questions have not, in the main, been pursued for their own sakes, but rather because negative answers to them have been thought to entail important consequences in the philosophy of mind, the theory of knowledge, and metaphysics.

One major question affected, bridging the first two of these areas, is that of skepticism about knowledge of other minds – which dissolves as unstatable if the answer to (2) is negative. Another, obviously central to the philosophy of mind, is that of the true meanings of *prima facie* EPI-words, which is obviously much affected by a "No" to (1).

(It might be thought that (1) was capable of resolving or dissolving skepticism about other minds without the assistance of (2). For if those ("private") aspects of our mental states on which the skeptic may with good prospects focus attention have no effect on what any word of our common language means, it would seem to follow that we cannot say anything to each other about those aspects, hence cannot pose the question of whether they are the same in others as they are in ourselves. But this overlooks the fact that, without a negative answer to (2), it still remains a possibility that each of us can formulate for ourselves the question "Are their EPI like mine?" and then doubt whether we can know the answer.)

In epistemology, a "No" to (2) poses problems for those "foundationalist" theories which purport to ground knowledge on beliefs about items that might be taken to be EPI; also for doctrines which "analyze" propositions about the *prima facie* public into propositions about the *prima facie* private, such as phenomenalism. It could be said that so long as (2) only speaks of what can/cannot be *said*, it doesn't affect these doctrines (which only require assumptions about what can be *thought*); but – apart from the fact that the implied distinction between being sayable and being thinkable may prove troublesome – one must consider that we shall find arguments being deployed against a private language which attack the notion of thought about one's EPI in the first instance, and language only derivatively.

Further (and more recently), the answer to (1) has been suggested (by Dummett) to be of critical importance in a central question of ontology: that of the debate between realists and anti-realists. (See Chapter 20, REALISM AND ITS OPPOSITIONS.) A negative answer, in Dummett's view, leaves the anti-realist in the ascendant. Later on we shall briefly consider whether (1) really is central for the realism versus anti-realism debate.

2 Private States and Public Language: The Possibility

Michael Dummett has denied that EPI can play any role in the semantics of the public language. For this view he advances a group of three closely related arguments, which we may call respectively the arguments from Communicability, from Acquisition, and from Manifestation.

Suppose that what I mean by some expression of the public language is affected by the nature of certain states epistemically private to me. Then, argues Dummett, that expression has a meaning which I will not be able to communicate to anyone else. Because the states are private, nobody else can know their nature, hence neither can they know what I mean by that expression. Others do not understand it, therefore it is not, after all, an instrument of the public language, which is by definition a vehicle of interpersonal understanding.

The Argument from Acquisition asks us to consider the position of learners acquiring the use of a language, some of whose expressions depend for their meaning on the nature of their teachers' EPI. Since *ex hypothesi* this is something they cannot know, they cannot make the associations needed to know what the expressions mean; in other words, they cannot acquire a grasp of the language.

The Argument from Manifestation looks at the same situation from the point of view of those who, like the teacher, have to judge whether or not the learners now use the expressions of the language with the accepted meanings. But if these meanings are affected by speakers' EPI, there is nothing the learners can do to "manifest" their understanding, no way in which they can let the competent speaker know that they have learnt their lesson properly.[1]

In short, if EPI affect meaning, then what anyone means is unknowable to anyone else, and language cannot serve mutual understanding or communication. Hence it is not a public language. Anyone who thinks that interpersonal communication is of the essence of language will be prepared to drop the word "public" from that sentence, and say that such a "language" is not a language, *tout court*; but so long as the possibility of a private language is undefeated we should stop at the narrower conclusion.[2]

It will be noted that all these arguments turn on the same point: if the meaning of other speakers' expressions depends on the nature of their EPI it cannot be known. They are thus very close relations of an argument that has frequently been directed at the classical empiricist

theory of meaning. That theory equated meanings (and thoughts) with image-like items entertained before the mind's eye, that is to say with some of the strongest candidates for epistemic privacy; so it had the intolerable consequence that nobody could know what anyone else meant or thought.

The most direct approach to the arguments from Communicability, Acquisition, and Manifestation will therefore be to ask two questions. First, is it true that if EPI have a role in semantics there can be no interpersonal knowledge of the meanings of the expressions in whose semantics they figure? Second, if that be so, how much does it matter? – is it the catastrophe that the arguments imply it to be, or can a supporter of EPI-semantics just take it in his stride?

The answer to the first question must be yes, since it follows straight from the definition of an EPI, given the principle that if A is an essential constituent of B, the nature of B can be known only if that of A is knowable too. But there is a complication which should be considered, if only to avoid being confused by it. This is the thought that until we have inspected the cases for and against skepticism about Other Minds, the traditional "Argument from Analogy," and the like, it must remain an open question whether we can know what someone else means, even if their meaning is determined, or partially determined, by their inner states.

In one respect the introduction of this thought at this point is just an irrelevance, for it is aimed not so much at the thesis that EPI can play no role in public-language semantics as at the question of whether there are any EPI at all, any facts about persons which are epistemically private in the defined sense. But in another respect, the matter of the *application* of the thesis rather than its internal logic, it is very much to the point, since it asks whether there is in fact anything at all about us which the thesis would, if true, exclude from semantics and pronounce incommunicable. We shall return to this later, though only briefly. Responses to skepticism about other minds are very varied, as are the conceptions of the mental which they trade upon or promote, so that a serious discussion of these possibilities would lead us too far away from our topic of the relation between private states and meaning.

So let us for the moment accept the obvious affirmative answer to our first question, and move to the second. One reason for announcing a catastrophe sufficient to discredit the position it follows from runs: Understanding someone is knowing what they mean. So if I don't know what you mean then I don't understand you. Hence any theory which makes the meaning of expressions of the public language dependent on EPI in effect denies that we understand each other when using these expressions; and that means that, by definition, they are not elements of the public language at all.

It may be doubted, however, whether understanding someone is necessarily to be equated with knowing what they mean. Accounts of the concept of knowledge vary, and some allow that knowledge exists where others deny it, so that any casual equation of understanding with knowledge of meaning needs more rigorous investigation. We may approach this, whilst keeping in touch with our main question, by considering the possible effects of what I shall call "Burke's Assumption":[3] we naturally assume that others have, in broadly similar external circumstances, broadly similar internal states. In so far as the latter are epistemically private there is no question of our knowing whether, or when, the assumption is true, but nevertheless it is one we all naturally make. Under exceptional circumstances (Fred can't see which traffic light is on, Mabel can't tell whether that is a trombone or a flute – whatever the incentive we offer them to get it right), we start to adjust our beliefs, but this is a departure from our first, firm inclinations. And let us assume further, that these assumptions are in fact mostly right.

Given Burke's Assumption, it will often be the case that speaker and hearer, teacher and pupil have the same, true beliefs about the qualities of each others' EPI; and hence there will no barrier in principle, and usually none in fact, to each arriving at the same, true beliefs about what the other means, even though their EPI affect their meaning. Is this enough for the operation of a public language in the semantics of which EPI have a role? And if it is enough, what of the assumptions that were necessary to allow us to reach this position?

To begin with the first question, we still have to admit that none of our speakers *knows* that the others mean what he takes them to mean. But this would not seem to prevent anyone from understanding anyone else. There is no particular reason to think that to understand correctly one must know that one understands correctly. And there seems to be no reason to deny that such true beliefs about the meanings that others attach to their expressions are enough to constitute understanding. After all, speakers will be expressing the thoughts that their hearers confidently take them to be expressing, and why should that be held to fall short of understanding them? They do not have any guarantee of mutual understanding, but why should there not be understanding without a guarantee?

Perhaps the objection is a rather different one, however. Whatever may or may not be required for understanding, it remains the case that we *do* know that we understand each other. And that rules out all theories which cast publicly unknowable items in any essential semantic role.

With this we are back at the point we touched on earlier, and the proponent of EPI-driven semantics has two lines of reply. One would be to adopt, at least as a defensive measure, some "externalist" account of knowledge such as reliabilism, and then point out that if we do make such assumptions as Burke suggested, and these assumptions are, in the main, correct, then our methods of coming to beliefs about other people's EPI are reliable, and the beliefs accordingly are knowledge; the supposed EPI aren't private after all. It still applies, admittedly, that if there are any states of persons about which others have no reliable ways of coming to true beliefs, then they really are EPI and can have no effect on the public language; but whether there are any, and if so which, becomes a very obscure and perhaps from the very nature of the case uninvestigatable question.

The trouble with this blocking response is that it relies on a particular, by no means uncontroversial, account of the concept of knowledge. And even if this account be accepted, the objector to EPI-semantics might well not agree that his worries had been adequately addressed. What the objector is really saying that there must surely be (quite independently of the correct analysis of "S knows that p," even if such a thing exists) is some good reason – something which we can see to be a good reason without needing to know already that the beliefs are true. And it is precisely this which there cannot be, with respect to our belief in mutual understanding, if EPI have any effect on meaning.

This argument will be as strong as the claim made by our objector, that there must be some reason (of an "internalist" kind) for this belief. How strong is that? Perhaps not very strong, for there is a plausible line of thought that sheds a good deal of doubt on it. Reaching a belief by reasoning to it from premises antecedently believed is a slow and uncertain process, easily thrown off course. Seeing that for practical purposes many beliefs are needed quickly, and with the degree of conviction necessary to give rise to immediate and decisive action, evolutionary development is not likely greatly to have favored it over "blind," as it were mechanical methods of acquiring beliefs. Once a certain level of sophistication has been reached, the power of reasoning, used at the right time and place, may become a most valuable way of extending our stock of beliefs; but there are no grounds for thinking that it

took much part in the beginnings of human mental activity when our basic types of belief and methods of forming them were being developed. What happened then was that we grew some successful psychological hardware. But that means that when we now consider some class of beliefs (such as those involved in Burke's Assumption), we are not entitled to *assume* that they must be retrospectively certifiable by any process of rational inference; they may turn out to be so, and then again they may not. And one thing we should certainly not do is think that they must be rationally certifiable just because we find them so convincing.

If allowed, this argument seriously weakens the claim that, since it would mean that in many cases we could give no good reason for thinking that we understand each other, EPI can have no part in semantics. For perhaps we can give no such reason. But some may think that the argument ought not to be allowed, after all. They can point to the unquestionable fact that there are many beliefs that we almost certainly would not have unless we could give reasons for them, and then they *may* be able to argue that the belief in mutual understanding is likely to be one of them. How to turn this possibility into a concrete proposal, however, is not obvious; and the present writer knows of no published attempt to do so.

Those who think that the nature of speakers' EPI may, without disaster, be assigned a role in the meaning of expressions of the public language thus seem to have the better of this phase of the argument, if only perhaps for the time being: at least until further arguments are brought, they can stave off the objection that their proposal puts our confidence in mutual understanding beyond the scope of rational support. But there is another, quite different line of attack against which they will also have to defend themselves.

The idea was to achieve mutual understanding, without banishing EPI from semantics, by relying on Burke's Assumption. More explicitly, we were to suppose that we all have a strong tendency to attribute to others EPI like our own under like circumstances, and that this tendency mostly leads us to true beliefs. The first type of objection focused on the *consequences* of this supposition, and turned on the question of whether they were unacceptably skeptical or not. The second type of objection is directed at Burke's Assumption itself: does it really make sense? Whether true or false, Burke's Assumption makes essential use of the notion of interpersonal comparison of inner states: we generally assume, it says, that those of others are similar to our own. It has been argued, however, and in more than one way, that this notion is in fact incoherent.

One such line of argument comes, unsurprisingly, from verificationism. Any doctrine which links meaningfulness at all closely to verifiability, whatever may be the exact nature of the link, is bound to find difficulty in alleged comparisons between the EPI of different persons. For since no subject can, in principle, have knowledge of both terms, any such comparison is as good an example of unverifiability-in-principle as can be found in a sentence that neither introduces "nonsense" vocabulary nor flouts any basic rule of grammar. If verificationism doesn't exclude this as meaningless, how could it exclude anything that we wouldn't all exclude anyway?

Nothing can safely be concluded from this, however. Notoriously, it proved extremely difficult even to formulate the verification principle in any way fully satisfactory to its proponents; so it is hardly surprising that the few published attempts to argue for its acceptance have turned out inconclusive. In any case, those likely to accept directly verificationist lines of thought are nowadays far fewer than was the case a generation ago. (See Chapter 4, MEANING, USE, VERIFICATION.) A much more fashionable assault on Burke's Assumption issues from Wittgenstein's discussion of rules and what it is to follow them.

Saul Kripke (1982) has offered an argument inspired by Wittgenstein's writings on rule-following, if not actually to be found in them. Suppose that a speaker uses a word on some occasion in the same way, that is to say with the same meaning, as he has used it on an earlier occasion. There must be something in virtue of which his present use of the word is consistent with previous uses (rather than having another, new meaning on this occasion). What could this something be? It cannot be either a publicly observable fact about him or his behavior, or a fact about his inner mental state.[4] So it cannot be a fact solely about *him* at all, but must include something about the behavior of other speakers of his community, to the effect that they would speak as he does in these circumstances, or regard his way of speaking as correct. The notion of sameness or consistency of meaning therefore demands the existence of some communal practice and is illusory without it.

If this be true (a very difficult buck which I here thankfully pass), then there is certainly a *prima facie* threat to the participation of EPI in semantics. I think we may take it that meaning is not a property of totally isolated utterances, but arises because expressions, and ways of combining them, are used consistently in accordance with specific rules. It follows that something can be a factor in the meaning of an expression only if it relates in a consistent way to the use of that expression, which means that, whatever it is, there must be a coherent notion of its being "the same thing again" or "another of the same sort." Is there any such notion where EPI are concerned? On the assumptions we are making about the outcome of the rule-following debate, that reduces to the question of whether, as regards the description of EPI, there is such a thing as communal agreed practice. And the temptation is to say no, precisely because they are private.

Before succumbing to it, however, there is a somewhat convoluted line of thought which we need to follow through. To start with, note that the principle about communal practice will surely have to be hypothetical in form, a matter of how others *would* describe something if they were well placed to do so. Otherwise we invite the result that if some potholer is the only person ever to see a certain underground rock formation, he cannot possibly describe it, either correctly or incorrectly. So perhaps our question should be not: How do others describe my EPI? but rather: How would others describe my EPI if they were well placed to do so?

Now this might seem the right moment to say that others never are or could be well placed to describe my EPI, precisely because they are private to me. So our conditional ("If others were well placed …") isn't assessable, even in principle, and the original temptation beckons again. Easiest would be just to give in to it; but we shouldn't, because if Burke's Assumption is true, then we frequently are well placed to describe other people's EPI. Perhaps we aren't *as well placed as they are*, but why should that be necessary? For after all, the requirement we allowed ourselves to start from, provisionally accepting it as a consequence of the rule-following debate, was the need for "communal practice." It would be a further thing to demand that this communal practice be based on *knowledge* of the items being described. Whether it could be justified or not could only be settled by a detailed scrutiny of the arguments about rules; but since it has not been established uncontroversially that even our provisional assumption really does follow from them, the prospects for a yet stronger version specifying knowledge as an essential basis of the communal practice must be quite doubtful.

It appears likely, then, that this type of attack on Burke's Assumption merely begs the question; its pivotal claim, that no relevant communal practice exists, can be made only when it has *already* been shown that Burke's Assumption is false, or incoherent. The possibility that EPI may have a part to play in the semantics of a public language remains open.

Another line of attack begins with the arguments against the possibility of a private language. If these arguments show that we cannot communicate with ourselves (or perhaps it should be "our later selves") about our EPI, then surely *a fortiori* we cannot communicate with others? But even this question is cloudy. It was pointed out earlier that the *locus classicus*, Wittgenstein's *Philosophical Investigations*, §243, actually offers two definitions of a private language. Wittgenstein appears to have assumed that a language in which someone speaks of "what can only be known to the person speaking; … his immediate private sensations" would necessarily be one which others could not understand. But our argument so far suggests that this may well be mistaken, in which event the two definitions fall apart and clarity demands that we look at them and their consequences separately.

Fortunately we can quickly clear the air, at least to some extent. If a private language be defined as "a language which only one speaker can, in principle, understand," then its alleged impossibility can have no effect at all on the question of whether EPI can figure in the semantics of a language which many people can understand, *unless* we take it that such a language would refer to the speaker's EPI, and that that is the ultimate reason for its impossibility. Otherwise the notion of an epistemically private item will simply not get a foothold in the logic of the argument, and our investigation reaches a dead end. In effect, we find ourselves forced back to the definition of a private language in terms of EPI.

So: if a private language, understood as one in which speakers refer to their own EPI, had been shown to be impossible, wouldn't it follow that EPI had no role in the public language either? But still the mists won't disperse, because we have to answer that we can't yet say: it will depend on just why a private language is impossible. If the agreed reason is that for EPI there is no legitimate notion of "being the same" or "being of the same kind," then will this not affect the private and public questions equally?[5] Perhaps, but only if the reasons for declaring there to be no such notion apply to the public case as strongly as to the private case. If they are verificationist reasons, then surely they do; it is hard to imagine how interpersonal verification could be thought possible when intrapersonal verification was not. But what if they are reasons drawn from the rule-following debate, to the effect that meaningfulness calls for a social practice, in other words a multiplicity of speakers? Wouldn't they have force only against the private language, leaving the public language, where by definition there is more than one speaker, untouched?

If we find that last line of thought convincing, however, then that can only be because we are still conflating the two definitions of a private language. The definition we are now supposed to be concentrating on doesn't say anything about a private language having only one speaker; it defines a private language as one in which you refer to your own EPI. And the crucial point is that until our earlier arguments about understanding and Burke's Assumption have been decisively refuted, it remains possible that the public language may be a private language as well; for if the public language permits us to talk to each other about our EPI, then why not also to ourselves? The idea may sound paradoxical, but only if we are still caught up in the second half of Wittgenstein's unfortunate double definition, and so feel that a private language *must* be a language with only one speaker.

Contrary to much recent thought, then, it begins to seem quite possible that there are no conclusive reasons for banning EPI from the factors that can give expressions of the public language their meaning. But that only brings us to the next two questions: Provisionally accepting that it is *permissible* to do so, should we ever *actually* involve EPI in our account of meaning? And what difference will it make if we do?

3 Private States and Public Language: The Effects

The immediately obvious candidates for EPI-affected semantics are expressions which purport to describe sensations (like "itch" or "headache"), and those standing for properties at least plausibly thought of as powers to produce sensations of certain kinds (such as "red" or "shrill"). Here it is tempting to think that what a speaker means depends on the phenomenal quality of his experiences; and most people would take the view that, whereas there may be other examples, if there are to be any at all then these must be amongst them.

But even here there can seem to be two options. One is to give in happily to the temptation. The other is to stick to the idea that the function of the public language is the adjustment and coordination of behavior, and that anything surplus to that, whatever its standing, is no part of linguistic meaning; so that provided we agree about what is to be called "red," stop at red lights, anticipate sweetness in red apples, we agree on the meaning of "red," and would do even if our respective visual experiences were quite different. Plenty that is epistemically private is going on, on this view, when we see red lights or have headaches; but whatever its significance for human life, it doesn't affect the meanings of any of the expressions we use to talk to each other.

Coming at the present stage of the argument, however, this seems unmotivated. If we have already agreed that nothing bars EPI from playing a semantic role in principle, isn't it merely doctrinaire to insist that they never do so in fact? The restrictive view of the function of language described in the last paragraph has usually stemmed from a decision that only what is public can be of any import in semantics, and there is no obvious reason to stick to it if that decision is itself in doubt. Admittedly it is sometimes useful to distinguish between understanding a speaker's words and understanding the speaker, in the sense of knowing what it is like for them to be in the situation that their words describe: you may know exactly what is meant by my utterance "There's a snake coming toward me," whilst having no idea how I feel about it. But what principally makes the distinction useful in this case is that what I have said may be true *however* I feel about it; so it has no application to a case in which what I am doing is describing my feelings.

Anyone prepared to go this far, and to allow that private states may affect, indeed be objects of, public discourse, is already quite a long way away from what has become, since the *Philosophical Investigations*, more or less the standard position. But most recent interest in the question about the semantic role of private states arises from the belief, advocated by Michael Dummett, that a very deep and general metaphysical issue depends on it: whether it is permissible to take a realist view of the world.

That issue is naturally, if vaguely, understood in terms of the world's dependence on, or independence of, human styles of thought and methods of investigation. But Dummett would have it understood, at least in the first instance, as a question about the right form for a theory of meaning: should the meaning of a sentence ultimately be characterized in terms of its truth-conditions, or in terms of the conditions under which we regard it as assertible? We need not here concern ourselves with Dummett's reasons for recommending this question as a fruitful entrance to the debate about realism, but can concentrate on his view that a decision against any possible role for EPI promotes the "assertibility conditions" approach to semantics. (See Chapter 20, REALISM AND ITS OPPOSITIONS.)

Grasp of meaning, once any part is denied to EPI, must consist in the capacity for some kind of publicly accessible behavior. So argues Dummett, and he goes on to say what that behavior must be: recognition of the circumstances under which the sentence can properly

be asserted. We may think we understand sentences whose truth-conditions, if they obtain, we cannot recognize as obtaining. If so, we delude ourselves, since under those circumstances our understanding could not be manifested, but would have to consist in some epistemically private feature of our minds, in breach of the principle that EPI have no legitimate business in semantics. Assertibility conditions, not truth-conditions, must therefore be primary in a theory of meaning.

This argument certainly has some force, once we accept the ban on the private from which it starts. But two corners have to be negotiated before it can be fully convincing, and they should at least be signposted here. First, we have to consider whether the explicit recognition of the fact that certain conditions obtain really is the *only* sufficient way of manifesting grasp of the meaning of a sentence. Second, it may be asked whether such "explicit" recognition really is as publicly accessible a phenomenon as the proposed use of it demands.

Neither question is easily resolved. The first is obscured by the point that manifestation must mean manifestation to someone, in this case other speakers of the relevant part of the language, which is to say other human beings familiar with the subject-matter. But do we not then need to know in advance that we cannot entertain unverifiable thoughts? For if we can, may there not be numerous ways in which someone can manifest to others that he is thinking some such thought, and using a certain sentence to express it? If this is a thought we can entertain, perhaps we also have a shared pattern of reactions to it, a pattern that can signal to others that a speaker is indeed expressing it.

The second question raises the problem of the nature of intensional states. Recognizing something, in this case the obtaining of certain truth-conditions, is not just a matter of assenting *when* they obtain, but of doing so *because* they obtain, and because *they* obtain rather than because of some other conditions which accompany them. Thus the notion of recognition brings with it something which might be called the "perspective" of the subject who does the recognizing; and it is not obvious that this can be accounted for in terms restricted solely to publicly available features of the subject and the situation. Perhaps it can, but complex issues are involved.

So it should not be thought that anti-realism in the theory of meaning follows directly from the thesis that EPI can play no part in semantics. On the other hand, it would be just as bad a mistake to think that if that thesis is shown to be groundless we can at once help ourselves to meaning-theoretic realism. True, it would then have been shown that if we can entertain thoughts about states of affairs whose existence we could not in principle detect, those states of affairs could be the truth-conditions of sentences of a mutually understandable public language, regardless of whether entertaining such a thought called for the occurrence of certain private states. But we would still not have addressed the question of what it would be to think such a thought; nor would that question necessarily be any easier just because we were allowed to appeal to EPI in answering it.

4 The Possibility of a Private Language

We now return to the second question broached at the beginning of this chapter: the possibility of a language in which a subject can, comprehensibly at any rate to himself, express thoughts about his own private states. This question is for historical reasons now inseparably connected with certain passages from Wittgenstein's *Philosophical Investigations*, and any treatment of it must take account of them; but they will be used

here simply as the obvious door to the debate, and no attempt will be made to decide any of the trickier questions of Wittgensteinian exegesis.

It was remarked in §1 of this chapter that Wittgenstein introduces the notion of a private language with a double definition; its words are to "refer to what can only be known to the speaker" (his "immediate private sensations") – and it is a language which no one else can understand. It will be obvious from §2 that I would wish to drop the second clause from consideration as causing far more trouble than it is worth. We shall concentrate on the idea of a language with terms that refer to a speaker's own EPI, and the crucial question is whether even the speaker himself could understand it, whether it really could be a language even for him.

But that way of putting it, though it has become standard, still does not reliably capture quite what most philosophers have had in mind when thinking about private language. What is essential is not so much the idea of terms that have the speaker's EPI for their *reference*, but rather of terms whose sense or meaning depends in some degree on the nature of the EPI of the person using them. It is, of course, true that some such terms, by virtue of their meaning, may well be usable to refer to the speaker's EPI; and it is also true that Wittgenstein's most famous example is about the (purported) use of just such a term to record recurrences of a particular type of sensation (see Wittgenstein, 1953, §258). Nevertheless, the wider formulation just suggested will serve us better. It covers more possibilities; it gives a closer parallel with the question about EPI and public-language semantics discussed in earlier sections; and the arguments of the private-language debate as actually conducted apply to it at least as well as they do to the version which, by following the standard translation of *Philosophical Investigations*, §243, makes the notion of reference sound primary.

All who argue the impossibility of a private language, and all those who defend private language against them, seem agreed on one central point: that meaningfulness requires the rule-governed, or at the very least consistent, use of a symbol; so that whatever it is about the use of a word which determines its meaning must be capable of *recurrence*, of being the *same again*. That principle has an obvious consequence for the words of a private language: epistemically private items, or those aspects of them which affect the meanings of the private vocabulary, must be the sort of thing which can repeat: it must be possible for there to be *another thing of that kind*. And this simple commitment is, according to various arguments, the Achilles' heel of the idea of a private language.

One such line of argument makes appeal to verificationism. Whether it is to be found in Wittgenstein is a matter of controversy, but there is little room for doubt that verificationism was at least one of the planks on which Schlick rested certain negative claims about private language (though he did not use that expression) in lectures given in London in 1932 (see Schlick, 1938, pp. 177–179). The critical question for him was, anticipatably, whether a color seen today was of *the same* shade as one seen yesterday. What did it mean? That was to be determined, he said, by looking at the way in which an answer could be tested. So long as we were allowed to resort to such things as the opinions of other people, the persistence of the colored object, and the empirically determinable probability of its having changed color, no special problem arose. But it was quite otherwise, Schlick held, in a case in which there was nothing to appeal to beyond the memory of the person making the judgment. In that case we should

> have to declare it impossible to distinguish between a trustworthy and a deceptive memory; we therefore could not even raise the question whether it was deceptive or not; there would be no

> sense in speaking of an "error" of our memory…. I recall it so, and that is final; in our supposed case I cannot go on asking: do I remember correctly? for I could not possibly explain what I meant by such a question. (Schlick, 1938, p. 179)

Not even in communication with oneself, Schlick concluded, can words convey the nature of a private experience.[6]

Now in so far as this argument rests on the principle that the meaning of a statement is its method of verification, few philosophers nowadays will rush to endorse it; even fewer in so far as it is felt to rest on an application of the "Picture Theory of Meaning."[7] And, as all readers of Wittgenstein will have recognized, the above passage bears a striking resemblance to parts of the *Philosophical Investigations*, striking enough to raise the question whether Wittgenstein really added anything new. But it is widely held that he did: that the *Investigations* contain an argument to the impossibility of a private language that makes no use of either the picture theory or of the verification principle.

This argument is usually located in §258, where Wittgenstein asks how the user of the private language is to give meaning to its signs. An inward ostensive definition, with the attention concentrated on the relevant private item, will be just an idle ceremony of no semantic consequence unless it brings about consistent usage: the "speaker" really does thereafter apply the sign correctly, that is to say in connection with EPI of *that* type. The trouble is that

> in the present case I have no criterion of correctness. One would like to say: whatever is going to seem right to me is right. And that only means that here we can't talk about "right."

In that event, Wittgenstein leaves us to conclude, there is no difference between a language and what merely seems to its "speaker" to be a language. And that only means that here we can't talk about a language. What vitiates private language is the collapse, in the case of EPI, of the distinction between "seems" and "is."

A distraction at this stage is the notion, introduced in §258, of an ostensive definition. Earlier in the *Philosophical Investigations* (see Wittgenstein, 1953, §28 and following) Wittgenstein discusses the business of giving meaning by ostension, arguing that its effectiveness depends on a great deal of cooperation from the recipient of the definition, who needs the right antecedent mental "set" if he is to discern what kind of thing is being pointed out as an example of the term. It is often suggested, not implausibly in view of §§257–258, that these thoughts about ostensive definition are part of Wittgenstein's weaponry against private language.

If they are, it is because, in Wittgenstein's opinion, ostensive definition can work only under conditions which the private linguist doesn't satisfy. Such at least seems to be the message of §257: "a great deal of stage-setting in the language is presupposed." And the implication of the last sentence of the paragraph is that the stage-setting in this case has to come from the public language, in particular from its use of the word "pain."

This raises a little swarm of questions. In the first place, is what is at issue here the possibility of a private language as, following *Philosophical Investigations*, §243, we defined it earlier? Or is it rather the possibility of having a private language whilst not speaking any public language? For it looks as if the most that §257 will show is the impossibility of the latter, and not of the former. (If the would-be private linguist does have the use of the word "pain" in public English, why should he not build on it a term designed to express the particular character of certain pains of his?)

Second, we should note that though ostensive definition calls for prior "stage-setting," it cannot always call for prior stage-setting *in a language*, since otherwise we could never get started. So the claim that our private linguist requires part of the public language as his stage, rather than just a particular mental set, needs special argument and shouldn't be accepted without it.

Third, we should notice the way in which §257 begins: we are to imagine a special situation, in which human beings have pains but show no outward signs of having them. Now it is quite reasonable to suppose that, under those circumstances, that part of the public vocabulary could not be taught, and so would not exist. So if there were good grounds to think that "stage-setting" of that kind would be necessary for the inner ostensive definition to work, then a private language might well turn out to be impossible. But that would have been shown to hold, we have to remember, only for the imaginary circumstances posited at the beginning of the paragraph. We could then react in two ways: we could either say that this shows nothing at all about the impossibility of a private language under the actual conditions of human life, or we could modify our understanding of what a private language is supposed to be.

The necessary modification would be to think of an EPI not just as something the nature of which could be known only to its experiencing subject, but to require also that there should be no outward sign of its occurrence. Such an extra load on the concept of an EPI would render the thesis that private language is impossible weaker and very much less important. This can be seen by reflecting that it could be accepted by the most unreconstructed Cartesians, provided that they were prepared to say that some outwardly observable feature of the material body went along with every inward feature of the mental substance of the mind, and that they would not then have to alter their views about the nature of the mental in any way at all. It would therefore be much more to the point if we could show the impossibility of private language on the old, unrevised concept of the epistemically private.[8]

Back then to the argument from the collapse of the seems/is distinction. Why is it held to have collapsed? Why shouldn't whether this EPI of mine really is of the same kind as that of yesterday be one question, whether it seems to me to be the same another? One line, we have seen, is to say that the only way to verify an answer to the first question is to ask the second – and then conclude that the two questions can't, after all, be distinguished. No more about the verificationism of that argument; but it is worth asking whether its other premise ('the only way to verify an answer to the first question is to ask the second') is true.

It could be said that the only way to verify an answer to any question at all is to find out whether it seems to us to be the right answer. But for most questions that will be true only if "seeming to us to be the right answer" is allowed to describe the result of a complex procedure in which several avenues of inquiry lead us to the same point. (What we seem to see coincides with what we seem to hear, with what Fred and Mabel seem to be telling us, and with our memory of what is normal under the circumstances seeming to obtain, for instance.) It is this that gives the seems/is distinction content: it becomes possible that something might seem, by one investigative route, what it turned out (on the witness of the other routes) not to be. And what causes the trouble for the private linguist is that in the case of an EPI there is none of this complexity, only a once-and-for-all judgment, unanswerable to any further investigation, that it seems to be of the right kind. But is that true? Must all judgments about EPI have this "one-track," structureless character?

Some writers have thought not, but suggest that there is no reason of principle why EPI should not fall into patterns and exhibit regularities (see, e.g., Harrison, 1974, ch. 6,

especially §37). One might add that there is a powerful *de facto* reason why they should: since they are our perceptual states, they must exhibit all manner of regularities if we are to perceive a stable and regular world, as of course we do. And if so, there will be more than one question which the private linguist can ask when trying to decide whether a particular item was of a certain type or not. Besides just "Did it strike me as being of that type?" there is also "Did it seem to be accompanied by the items that usually – as it seems to me – accompany items of that type?" A response to this would have to take one of two courses: either to retreat, saying that the argument only applied to such EPI as don't fall into any such patterns, whilst allowing a private language to encompass all that do; or to argue that the existence of such patterns would have no tendency to reinstate the seems/is distinction.

If we are hoping for a robust version of the anti-private-language thesis, only the second option will be of much interest. Its proponents must tread carefully, lest their reasons for denying the seems/is distinction in the private case get out of hand and threaten the distinction for public objects, thus undermining public language as well. The threat is serious enough, since it might well be thought that the only thing that enables us to make a distinction at all between seeming to be and actually being is the existence of *various ways* in which a given proposition may seem to be true, so that we can think of being true as the concurrence of the different ways of seeming true.

Suppose, then, that this debate turns out in favor of the seems/is distinction for EPI and their properties. Would that reinstate private language? Not by itself. Perhaps two EPI of mine do each possess the feature F, but in order that my word W should apply to them both something else is needed: that W really is my word for F-ness. It is not enough that I do in fact utter W whenever this type of EPI occurs. (I may say "Ouch" whenever a certain type of EPI afflicts me; that does not make "Ouch" *mean* that sort of inner state.) Somehow, most likely to do with my intentions regarding it, I must have given the word W meaning. So: under what conditions can there be meaning, and stable intentions, and does the private linguist fulfill them?[9]

It can certainly be doubted. Saul Kripke (1982) ties the rejection of private language to Wittgenstein's views on following rules, drawing attention in particular to *Philosophical Investigations*, §§201–202 and seeing it as an outcome of the material beginning around §139. Here we are harking back, of course, to the position sketched in §2 of this chapter: meaning requires consistency of use, and consistency can be understood only against the background of communal practice. Therefore no facts about an isolated individual are sufficient to confer meaning; and isn't the speaker of a private language isolated in the relevant sense?

If we take a private language to be one which only its speaker can understand, presumably the answer is yes. But we have seen reason to ignore that part of Wittgenstein's double definition, and think of private language as defined by the epistemic privacy of the objects to which its terms refer. Then the question is less straightforward, since it seems possible (at least until Burke's Assumption can be refuted) that there may be communal linguistic practice relating to EPI; this because Burke's Assumption would allow us to have, and express, beliefs about the private states of others, even though we cannot *know* what these states are like. It will allow us to confirm, from our own impressions, others' statements about their EPI, even to reject their claims on occasion, at least where insincerity or inattention is suspected. So a private language still seems possible; indeed, it looks possible that the public language may also be a private one, in that each of us can use it for referring to their EPI.

Can it be countered at this stage that what we have just described does not count as a communal practice in the required sense, because the required sense demands a practice amongst (so to speak) epistemically equal partners? Without going further into the concept of epistemic equality, it does seem reasonable to agree that Burke's Assumption will not provide it; but will the argument from rule-following really justify the demand? After all, the practice described above is not a mere sham, in which one person makes a statement about their EPI and everyone else respectfully parrots it; the participants are making independent judgments, even if one of them has a favored vantage point. The rule-following arguments are fascinating; they are also complex and controversial, and there must be some room for doubt as to whether they prove the necessity for a communal practice at all. To demand a proof of the need for a community of *epistemically equal* individuals is to impose a substantial further burden on them. Perhaps they can bear it; but that needs to be shown carefully and explicitly.

Two relatively minor points should be mentioned. Christopher Peacocke has proposed what he calls the "Discrimination Principle," claiming that it rules out private language (Peacocke, 1988, especially pp. 491–493). He states it as follows:

> for each content a speaker may judge, there is an adequately individuating account of what makes it the case that he is judging that content rather than any other. (Peacocke, 1988, p. 468)

If, then, p and q are different judgments, there must be something about the act of judging that p which distinguishes it from the act of judging that q. And there are propositions which the supporter of private language will have to claim it possible to judge, which, however, do not satisfy the Discrimination Principle with respect to some other proposition which he is committed to distinguishing from them.

We need not enter into the details of the argument. For whilst this approach may offer a *framework* for discussion of the possibility of a private language, or of many other issues, it cannot by itself settle anything. The Discrimination Principle is nothing but a special case of the trivial truth that if two things are different in respect of a certain property (in this case two judgments in respect of their content), then there is some difference between them relevant to the property in question. And from this nothing can follow as to which particular judgments are legitimate, which spurious, until we add some more substantial premises telling us which factors can be relevant to the content of a judgment. But that falls little short of saying: until we add a theory of meaning. The Discrimination Principle leaves everything still to be contested.

Finally, there is one early approach that can with some confidence be written off: the private-language argument is not, and never really has been, based on skepticism about the memory when exercised about previous EPI. A. J. Ayer (Ayer, 1954) appears to have taken it in this way, and consequently had little difficulty in disposing of it with the counter that reliance on memory was equally necessary for the verification of utterances in the public language. Certain it is that this line has no prospects whatever unless backed up by reasons for thinking memory especially fallible in the private case. And this is not what has been argued – not by Schlick, and not, on any plausible account of his intentions, by Wittgenstein. Their view was not that our memory is especially likely to fail us where the properties of past EPI are in question; it was, rather, that there are no genuine statements or thoughts, and hence nothing for the memory to report, whether truly or falsely, reliably or not.

Notes

1 For further discussion of these arguments, see Chapter 20, REALISM AND ITS OPPOSITIONS, §2.

2 We can see already the need to treat the private-language question separately; for all the above arguments turn on the unknowability of an EPI by *others*, and so clearly do not apply to the case of a private language, where there are no others to be considered.

3 In Craig (1982) I called this "the assumption of uniformity." Readers should take it that only the ugly name has been changed. Edmund Burke wrote (1757, p. 13):

> We do and must suppose, that as the conformation of their organs are nearly, or altogether the same in all men, so the manner of perceiving external objects is in all men the same, or with little difference.

4 Here I just baldly state the next major lemma of the argument. Fuller discussion will be found elsewhere in this volume: see Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING, §2.

5 Given, that is, the assumption that meaningfulness always involves rules, so that whatever is relevant to meaning must be capable of playing the same role consistently.

6 Schlick favors putting all this in terms of a distinction between "Form" and "Content," thus introducing complexities which I have here attempted to skirt round. His main thesis throughout this sequence of lectures is that language can convey only Form, never Content, and this he bases on a view of meaning not wholly unrelated to the notorious "Picture Theory" of Wittgenstein's *Tractatus Logico-Philosophicus*, to the effect that an utterance can only express a fact if it shares its Form. Some may like to read the lectures with this connection in mind.

7 See n. 6 above.

8 It might be thought that the revision cannot be avoided, since only events which had no corresponding outward sign could be epistemically private in the original sense. But this seems wrong; the fact that an inner state has an externally observable correlate means that others have a clue as to when it is occurring, but that is far from saying that the outward sign is so revealing that they can know from it what the inner event is like.

9 In this connection see Wright (1991).

Postscript

GUY LONGWORTH

Two central questions about meaning and privacy are the following. First, could there be a private language – a language the expressions of which have meanings that are available in principle to only one person? Second, assuming that the languages that we employ are not entirely private in that broad sense – so that at least some of the meanings they carry are available, in principle, to pluralities of speakers – does that fact serve to rule out otherwise plausible views about the natures of those meanings? In particular, does it rule out views on which meanings determine reference to elements about which only one person can know? The earlier part of this chapter focused largely on the second question, and this part retains that focus. (For discussion of the former question, with reference to Wittgenstein's important discussions, see Wright, 1986, and Stern, 2011.)

I'll focus on a specific range of issues that arise from the conjecture that the meanings of some of an individual's expressions purport to determine reference to objects, conditions, processes, or occurrences that are private to that individual – say, the individual's experiences, or aspects of their experiences. And I'll begin with an initial characterization of what it is for such referents to be private, according to which their privacy entails that they are such that only one person can have propositional knowledge about their existence (or obtaining, occurrence, or unfolding) or their intrinsic properties. (The qualification that the properties be intrinsic is aimed at finessing technical issues that arise from someone knowing, about a referent, only that they know almost nothing about that referent.) We'll later briefly consider a weakening of the operative characterization of privacy. (For discussion of Wittgenstein's animadversions against the claim that experiences, or aspects of experience, are private see Snowdon, 2011.)

A natural and popular view is that understanding an expression is a matter of knowing what it means. More specifically, it might be held that one understands a use of an expression if and only if, for some meaning *M*, one knows that the expression, as so used, means *M*. Suppose in addition that propositional knowledge of the meaning of an expression requires propositional knowledge about the referents determined by the expression. That is, suppose that one knows that an expression means *M* only if, for all referents *R* determined by *M*, one knows that the expression refers to *R*. On that supposition, the natural view about understanding would deliver a straightforward argument from the privacy of referents to the impossibility of more than one person understanding an expression the meaning of which determined those referents. However, there are apparently reasonable grounds for skepticism about the natural view of understanding.

Is it true, then, that if one understands an expression, then there is a meaning *M* such that one knows that the expression means *M*? In the earlier part of the chapter, the claim was challenged on the grounds that reliably true belief about what expressions mean – perhaps as supported by further reliably true belief that the beliefs about meaning are reliably true – might suffice for understanding those expressions. (See the discussion there of what Craig calls Burke's Assumption, pp. 252–257, 263–264.)

Additional grounds for doubt may be provided by reflection on cases in which a speaker appears to understand the use of an expression and yet appears not to meet plausible conditions on knowing what it means. For instance, it's a plausible necessary condition on knowing what an expression means that one has relevant beliefs about what it means – for example, that where one knows that the expression means *M*, one believes that it means *M*. However, consider a case in which you believe that you are in the control of an evil super scientist who has made it so that all of your present experience is hallucinatory. Because of your belief about your circumstances, you withhold belief in how things appear experientially to you. Thus, for example, when you have an experience of a person talking to you, you take it to be the upshot of a hallucination and so do not form the belief that there is someone talking to you. And when you have an experience of the person saying to you that it's a nice day, you fail to form the belief that the person has said to you that it's a nice day. So, you don't believe that the person said to you that it's a nice day. On the assumption that it's impossible for one to know that they said that it's a nice day if one doesn't believe that they said that it's a nice day, this would be a circumstance in which you don't know that they said that it's a nice day. Despite that, it's plausible that – since the person did in fact say that, and you were aware of them doing so – you understood what they said. So, there are plausible grounds for allowing that it's possible to understand what someone said – or to know what, on that occasion, they meant – without knowing what they said. (See Hunter, 1998; Longworth, 2008.)

Another way of generating such doubts would be the following. It's a plausible condition on knowing that such-and-such that, in believing as one does, one couldn't too easily have been wrong. Thus, if, in sufficiently similar circumstances, one would have formed a similar belief, in a sufficiently similar way, and yet that belief would have been false, then it's plausible that, in the actual case, one doesn't know. One wouldn't know because one's true belief could too easily have been false. Given that plausible condition on knowing, grounds for doubt about the claim that if one understands, then one knows, would be provided by plausible cases in which one understood an expression by believing it to mean what it in fact means, and yet one's belief could too easily have been false.

Consider the following case. Imagine that you have acquired competence in English via a normal route. Normally, we can imagine, you are in a position to understand what people are saying to you in English and, moreover, to know what they are saying to you. However, your present circumstances are not normal. You are presently under the control of an evil super scientist, so that the vast majority of your present experiences are hallucinatory. Although the contents of your hallucinatory experiences are prosaic, their natures are such that most of the beliefs that you form naturally on their basis will be false. However, for a few moments each day the scientist relinquishes control of your experience, in such a way that the transition between hallucinatory and genuine experience is not noticeable. During one of these periods, the scientist speaks to you in English, saying to you that it's a nice day. Plausibly, during your brief respite from hallucinations, it is possible for you to see and hear the scientist speaking to you. That is so, despite the fact that it is plausibly impossible for beliefs that you form on the basis of what you see and hear in those circumstances to be

knowledgeable, since it would be so easy for you to have so believed and to have been wrong. Furthermore, and of more immediate relevance, it's plausible that it's possible for you to understand what the scientist says to you. Again, that seems plausible despite the fact that it's plausible that you can't know what the scientist is saying to you since it would be so easy for you to have so believed that he was saying it and to have been wrong. So, it's plausible that it's possible to understand what was said in one's presence even in cases in which one doesn't know what was said. (See Pettit, 2002; Longworth, 2008.)

Suppose that that's right. It would follow that it's possible to meet necessary conditions on understanding what was said without thereby meeting sufficient conditions on knowing what was said. In that case, even if we were to accept that it is not possible for one to know what was said – because, for example, that would require knowledge about the referents of what was said, and that is precluded because of their privacy – it wouldn't follow immediately that it is not possible to understand what was said. For it may be that the reason that knowledge of what was said is precluded is because one's circumstances mean that there is too great a danger that one's beliefs about what was said might be false. Since – by the present supposition – one can understand what was said even in cases in which there is a significant danger of believing falsely, that would present no bar on one's understanding what was said.

In summary, whether the impossibility of knowing what an expression is used to mean translates into the impossibility of understanding what the expression is used to mean depends on two factors. First, it depends on which conditions on knowing figure in determining the impossibility of knowing what the expression means. And, second, it depends on whether those conditions are also conditions on understanding what the expression means.

Let's set that issue to one side and turn to a different range of issues that arise if we assume that understanding what is said requires knowing what is said. The initial characterization of privacy about referents was that a private referent is something such that only one person can have propositional knowledge about its existence or its intrinsic properties. It might seem to follow straightforwardly from that characterization of privacy that it's impossible for more than one person to know what someone says about such a private referent. As a concession to that line of thought, let's assume that someone's saying something about such a referent entails that the referent occurred or that it has one or another intrinsic property. And suppose that a strong closure condition applies to knowing. Specifically, suppose that if one knows that *p*, and if it being so that *p* entails it being so that *q*, then one is in a position to know that *q*. (Compare Craig on p. 253.) Given those assumptions, it's plausible that no one other than the speaker could know what the speaker says about their private referents. For suppose that a speaker *A* says that *p*, and that they are the only person able to know about the existence or the intrinsic properties of a referent determined by the proposition that *p*. And now assume, for purposes of *reductio* that a speaker *B*, distinct from *A*, comes to know that *A* said that *p*. *A*'s having said that *p* entails that the referents determined by the proposition that *p* occurred or that they have one or another intrinsic property. By the strong closure condition, it follows from *B*'s knowing that *A* said that *p* that *B* is in a position to know that the referents occurred or that they have one or another intrinsic property. But by assumption, since at least one such referent is private according to the initial characterization, *B* is not in a position to know that that referent occurred or that it has one or another intrinsic property. And so, given our assumptions, the supposition that *B* knows that *A* said that *p* entails a contradiction and, so, must be rejected.

An obvious problem with that derivation is that it depends upon the correctness of the strong closure condition. For the strong closure condition is obviously too strong, entailing,

for example, that if one knows the Peano–Dedekind axioms, then – regardless of one's knowledge of what those axioms entail – one is thereby in a position to know all arithmetical facts. Furthermore, the natural weakening of the closure condition would be too weak to deliver the required conclusion. For the natural weakening would be the following: if one knows that *p*, and if *one knows* that it being so that *p* entails it being so that *q*, then one is in a position to know that *q*. And that condition would have as a consequence that it is impossible for *B* to know that *A* said that *p* only if *B knew*, of the private referents determined by *A*'s saying that *p*, that *A*'s having said that *p* entails that those private referents occurred or that they had one or another intrinsic property. Not only is there no immediate reason to think that an arbitrary *B must* have the required knowledge but, in addition, there is reason to think that, because of the privacy of the subject-matter of the entailment's consequent, *B can't* have the required knowledge. So, even if the weaker closure condition were acceptable – and even the weaker condition is, at best, controversial – it would not obviously furnish the required connection between the knowledge of meanings and knowledge of referents determined by those meanings. (See, e.g., Dretske, 1970; Hawthorne, 2005.)

Perhaps, however, there is an alternative form of closure condition that is more plausible than the strong closure condition and that, in addition, sustains the required consequence. Although it doesn't appear to be true in general that knowledge is closed under entailment, perhaps it's true that knowledge is closed under a subclass of cases of entailment. Suppose that the subclass could be shown to include all cases in which the entailment relation is underwritten by the connection between someone saying something and the existence or the intrinsic qualities of the referents that are determined by what they say. In that case, closure would apply in the case at issue, connecting knowledge of what *A* said and knowledge about the private referents determined by what *A* said. And that would suffice to reinstate the conclusion that *B* cannot know what *A* said.

Rather than pursue the large and delicate question whether the required form of closure condition is defensible, I propose instead to consider a more local issue. Assume that the required form of local closure condition is correct. We've seen that that closure condition, in conjunction with referents that are private according to our initial characterization, entails that at most one person can understand what is said when what is said determines those referents. For according to the initial characterization of a private referent, it is something such that only one person can have propositional knowledge about its existence or intrinsic properties. The difficulty with that as an argument to our target conclusion is that in assuming that initial characterization of privacy, it seems to assume an overly demanding conception of privacy.

The initial conception seems overly demanding for the following reason. It is liable to seem natural – at least to a proponent of private referents – to hold that there are referents that are available, for instance as objects of knowledge, in a particular way to only one person. For example, a proponent of private referents might hold that there are objects of private experiences that can be known in a peculiarly first-personal way only to their subject. Furthermore, it is arguable that, unlike objects of public experience, such referents can be known at first hand to only one person, the subject of the experience. However, even if such a conception of private referents were defensible, it would not immediately support the claim that such referents are unknowable to anyone other than their subject. In order to support the latter claim, a case would have to be made that such referents are not knowable at *second* hand, on the basis of understanding and accepting what the subject says about them.

The considerations that we've discussed to this point seem powerless to sustain such a case. For example, any such case would have to go beyond appeal to the weak closure condition considered above, on which knowledge is closed under known entailment. For the weak closure condition would serve, at most, to impose the requirement that one who understands what is said about a private referent is placed, thereby, in a position to acquire knowledge about that referent. (At most, since, as was noted above, it would deliver that result only with respect to subjects who knew the operative entailments.) And one might meet that condition via understanding what a subject tells one about the referent, even if no non-vicarious route to such knowledge were available to one. For example, one might gain the required epistemic position by reasoning from facts about meaning and facts about what those facts entail. What would be needed, in addition, in order to make the required case would be a defense of the further condition that one must be in a position to know the known entailments of what one knows independently, and in advance, of knowing the entailing facts. Furthermore, our ordinary judgments about cases seem consistent with allowing the possibility of purely second-hand knowledge about the things to which an interlocutor refers. For example, it seems possible for you to acquire knowledge about someone with whom you are not acquainted – say, my friend Kim – solely on the basis of my testimony about them. Argument would be required to show that one couldn't similarly come to know about another's private referents on the basis of their testimony. (See, e.g., Evans, 1982, pp. 122–129; 1985, pp. 6–8; Raven, 2008.)

Let me summarize the foregoing. I've considered the prospects for an argument from the privacy of a referent determined by the meaning of an expression to the impossibility of more than one person understanding a use of the expression. I considered a line of argument based on an initial characterization of privacy, according to which a private referent is something such that only one person can have propositional knowledge about its existence or intrinsic properties. The argument was, in effect, based upon two assumptions: first, that understanding the meaning of a use of an expression requires knowing the meaning of the expression; second, that knowing the meaning of an expression requires knowing about the referents of the expression. I suggested some grounds for doubting both assumptions. Finally, I suggested that the initial characterization of privacy might be too demanding. And the adoption of a more reasonable characterization of privacy would further dim the prospects for a compelling argument from privacy of referents to the impossibility of mutual understanding.

Tacit Knowledge

ALEXANDER MILLER

1 Introduction

Competent speakers of a natural language know what the sentences of that language mean. A theory of meaning for a natural language, if correct, specifies what each well-formed declarative sentence of that language means.[1] Thus, the following question naturally suggests itself: What sort of relationship, if any, obtains between speakers of, and a correct theory of meaning for, a given natural language? In this chapter I shall examine a number of answers that have been given in response to this question. In particular, I shall be considering whether any account of the relationship can provide an adequate justification for what has been an article of faith of those engaged in the construction of systematic theories of meaning for natural languages: the requirement that such theories be compositional. A theory of meaning is compositional if and only if (a) it has only finitely many proper (non-logical) axioms, and (b) each of the meaning-delivering theorems ("meaning-specifications") served up is generated from the axiomatic base in such a way that the semantic structure of the sentence concerned is thereby exhibited.[2]

What motivation is there for seeking compositional semantic theories in preference to their more readily available, non-compositional counterparts? Why should the construction of a semantic theory be constrained by the requirement that it reflect the semantic structure of the language concerned? As Crispin Wright notes, in a wide-ranging survey of these issues (1986; see also his 1980, ch. 15; 1981; 1988), the answer generally given to this question is that the construction of such theories is supposed to take us some way towards providing answers to each of the following three questions:

1. How is it possible, given the finitude of their capacities, for speakers of a natural language to understand a potential infinity of sentences?
2. How is it possible to *learn* a natural language?
3. How is it possible to understand utterances of previously unencountered sentences?

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

In what follows I shall ignore (1), and look only at (2) and (3). It is not clear to me what the claim that speakers understand a potentially infinite number of sentences amounts to and, in any case, as we shall see, Gareth Evans makes it clear that the demand for compositionality in semantic theories has nothing essentially to do with this alleged "potential infinity": it can be leveled with equal force at theories dealing with languages containing only a finite number of possible sentences. I shall proceed as follows. I begin, in §2, with Michael Dummett's idea that answers to (2) and (3) might be facilitated if competent speakers of a natural language can be credited with *tacit knowledge* of the axiomatic base of a compositional theory of meaning for their language. I shall then explain that viewing tacit knowledge of semantic axioms as a bona fide propositional attitude-state is implausible, because a plausible constraint (outlined by Evans and Wright) on a state's being a propositional attitude is thereby violated. In §3 I examine Gareth Evans's suggestion that ascription of tacit knowledge of a semantic theory can be empirically well founded, so long as we are clear that in ascribing it we are not ascribing a set of genuine propositional attitudes but only a set of *mere dispositions*, one for each primitive expression of the language, to the speaker. Crispin Wright has raised a number of objections against Evans's account, and in §4 I shall show that Evans's suggestion, as developed and modified by Martin Davies, has the resources to respond to those objections. §5 briefly looks at how the modified account can provide answers to questions (2) and (3) above. In §6 I argue that Wright's alternative to Davies's mirror constraint actually *presupposes* it. I finish, in §7, by considering whether the project of constructing semantic theories in accordance with the mirror constraint is in tension with Wittgenstein's reflections on rule-following.

2 Tacit Knowledge and Propositional Attitudes

Dummett writes:

> A theory of meaning will, then, represent the practical ability possessed by a speaker as consisting in his grasp of a set of propositions: since the speaker derives his understanding of a sentence from the meanings of its component words, these propositions will most naturally form a deductively connected system. The knowledge of these propositions that is attributed to a speaker can only be an implicit knowledge. In general, it cannot be demanded of someone who has any given practical ability that he have more than an implicit knowledge of those propositions by means of which we give a theoretical representation of that ability. (Dummett, 1976, p. 70)

It is clear from this passage that tacit knowledge of a semantic theory's axiomatic base is taken by Dummett to be a species of knowledge: that the state of tacitly knowing an axiom of such a theory is taken to be a propositional attitude-state, a state which represents the information codified in that axiom. As Wright comments,

> The explanatory ambitions of a theory of meaning would seem to be entirely dependent upon the permissibility of thinking of speakers of its object language as knowing the propositions which its axioms codify and of their deriving their understanding of (novel) sentences in a manner mirrored by the derivation, in the theory, of the appropriate theorems. (Wright, 1986, p. 207)

It is *tacit* knowledge because competent speakers will generally be unable to formulate the theory of meaning whose axiomatic base they tacitly know, and will generally be unable to recognize a correct formulation of the theory of meaning if it is presented to them. But for all

that, it is still knowledge, and knowledge of propositions. It is easy to see how this contributes to answering (2) and (3) above. Say that a language L is learnable when it is possible for its speakers "to come to know the meanings of all the sentences of L by way of exposure and projection" (Davies, 1981a, p. 60). Thus, we can say that a language is learnable when one needs explicit training with only a relatively small number of sentences in order to secure competence with a possibly very large set of sentences outwith that set. So we can see that to say that a language is learnable is just to say that speakers can understand novel utterances, without explicit training in their use. Question (2) collapses, therefore, for natural languages at any rate, into (3). And there is no problem for Dummett in answering (3): speakers can understand novel utterances because they have at their disposal the information, codified in their tacit knowledge of the theory of meaning for the relevant language, of the semantic properties of the sentence's parts. This tacit knowledge provides them with the resources for understanding the sentence, in the same way that the axioms of the theory of meaning provide the resources for the derivation of a meaning-specification for the relevant sentence.

There is, no doubt, much to be said about Dummett's idea. But for the rest of this section I want to focus on a set of arguments whose upshot is that, whatever tacit knowledge of the axiomatic base of a semantic theory is, it cannot be construed as a genuine propositional attitude or intentional state.

Evans and Wright have argued that there is a necessary condition which all genuine intentional states must satisfy to qualify as such, and that putative states of tacit knowledge of meaning-theoretic axioms do not satisfy this condition. In order to motivate this condition they ask us to contrast, on the one hand, the belief that a man might have to the effect that a certain substance is poisonous, with the disposition that a rat might have to avoid a similarly contaminated substance. Can we describe the rat as having a genuine belief that the substance is poisonous? Evans and Wright suggest not: for whereas in the case of the man the belief is, to use Evans's phrase, "at the service of many distinct projects," and can interact with others of his beliefs and desires to produce new beliefs and desires, none of this obtains in the case of the rat's disposition. In the case of the man, for instance, the belief could be at the service of projects such as killing an adversary, retaining good health, or getting out of an obligation by taking a small dose, to name but a few. None of this is possible in the case of the rat: the putative "belief" is harnessed to the single "project" of avoidance of the substance. This is supposed to be a reflection of the fact that propositional attitudes and intentional states, such as beliefs and desires, come in *articulated systems* or *holistic networks*. And it is because genuine beliefs come in such networks and can thus interact with other beliefs, that they can indeed be at the service of many distinct projects. For example, the man's belief that the substance is poisonous can be at the service of the project of getting out of a particular obligation because that belief can, together with the beliefs that a small amount of the substance causes only a mild illness and that a mild illness will release him from the obligation, lead to the belief that taking a small amount of the substance will enable him to avoid fulfilling the obligation.

A crude version of the constraint suggested by the Evans–Wright discussion might therefore run as follows:

> *Constraint 1*: A state P of an agent W is a genuine propositional attitude or intentional state only if P can interact with others of W's propositional attitudes and intentional states to produce new propositional attitudes or actions – thus putting P at the service of many distinct projects of the agent.[3]

Where does this leave the tacit knowledge a speaker might have of a meaning-theoretic axiom? Evans and Wright both claim that such a state of a speaker violates the constraint above. Far from being at the service of many distinct projects, the tacit knowledge is, says Evans,

> exclusively manifested in speaking and understanding a language; the information is not even potentially at the service of any other project of the agent, nor can it interact with any other beliefs of the agent (whether genuine beliefs or other "tacit" beliefs) to yield further beliefs (Evans, 1981, p. 133)

while Wright puts it like this:

> The (implicit) knowledge of a meaning-theoretic *axiom* would seem to be harnessed to the single project of forming beliefs about the content of sentences which contain the expression, or exemplify the mode of construction, which it concerns.

He asks the following (rhetorical) questions:

> What is supposed to be the role of *desire*? What is the (implicit?) desire which explains why the subject puts his axiomatic beliefs to just this use, and what are the different uses to which they might be put if his desires were different? (Wright, 1986, pp. 227–228)

No plausible answers to these questions suggest themselves, so the conclusion is that states of tacit knowledge of semantic axioms cannot plausibly be viewed as propositional attitudes. Evans appears to view the objection as applying to tacit knowledge *tout court*, that is, not only to states of tacit knowledge of axioms but also to states of tacit knowledge of meaning-theoretic *theorems*, which codify the rules governing the use of whole sentences. But Wright quite clearly sees the objection as applying only to tacit knowledge of the axioms; as he says, "someone who is credited with implicit knowledge of a meaning-delivering theorem may express his knowledge in an indefinite variety of ways, including, in appropriate contexts, lying, assent, and silence." So no reason emerges "to doubt the propriety of crediting [speakers] with implicit knowledge of the content of meaning-delivering theorems" (Wright, 1986, pp. 227 and 237–238). Thus, Wright's defense of genuinely intentional tacit knowledge of meaning-specifying theorems is in effect a claim that tacit knowledge of such theorems can be inferentially integrated with the rest of the agent's propositional attitudes in the manner required by Constraint 1.[4] But how can my semantic belief concerning the meaning of a given sentence interact with my propositional attitudes to give rise to new propositional attitudes? An example should suffice to convince us that this is indeed possible. I have a certain intentional state, the possession of which is constitutive of my understanding of the sentence "Catriona is getting married to Seamus on Saturday": this intentional state can interact with my belief that Catriona is getting married to Sean on Saturday to lead to the belief that the sentence "Catriona is getting married to Seamus on Saturday" is false; or it can interact with my desire to annoy Patrick (an unsuccessful suitor of Catriona's) to lead to the belief that I ought to utter "Catriona is getting married to Seamus" in Patrick's presence; and so on. Examples can quite easily be multiplied: this shows how the tacit knowledge of semantic theorems, unlike the tacit knowledge of semantic axioms, can indeed be at the service of many distinct projects of the agent concerned.

Let's suppose, as seems plausible, that Wright is correct in claiming that the objection just considered does not apply to states of tacit knowledge of the meaning-specifying

theorems, for the reason stated. Then the following question suggests itself: Why cannot we view the tacit knowledge of an axiom as a genuine intentional state after all, in virtue of the fact that although it is *directly* harnessed to the single project of forming beliefs about the content of sentences in which it figures, it can make an *indirect* contribution to the other projects of the agent *via* the states of tacit knowledge of the theorems corresponding to those sentences? The state of tacit knowledge of an axiom is at the service of many of the agent's projects because the project to which it is *directly* harnessed is itself at their service. Or equivalently, a state of "tacit knowledge" of an axiom can lead inferentially to a vast number of other propositional attitudes because it *can* lead inferentially to genuine intentional states (i.e., those that consist in implicit knowledge of the appropriate theorems), which *in turn* can lead to almost any other intentional state, modulo the other intentional states which we suppose the agent to possess.

So what is important in determining whether a state is a genuine propositional attitude is not the *number* of intentional states to which it can give rise, or the *number* of the agent's projects which it is at the service of; rather, what is crucial is the nature of the potential *routes* from the given state to the rest of the propositional attitudes, and the nature of the potential routes via which the information in question is placed at the service of a multiplicity of the agent's projects. I suggest, then, that in order to draw the required distinction in such a way that tacit knowledge of semantic axioms is excluded, we need something along the lines of the following amended version of Constraint 1:

> *Constraint 2*: A state P of an agent W is a genuine propositional attitude or intentional state *only if* P can interact *directly* with others of W's propositional attitudes and intentional states to produce new propositional attitudes and actions – thus putting P *immediately* at the service of many distinct projects of the agent.

Of course, the questions facing us now are: (a) What exactly do we mean by "directly" as it appears in Constraint 2? and (b) Does Constraint 2 provide us with a plausible means of drawing the distinction between intentional and non-intentional states?

Let's attempt to answer (a) first. We can say that a cognitive state P interacts directly with a given propositional attitude only if the interaction takes place without the mediation of some other propositional attitude R in the causal generation of which P plays a part. Getting clear on why states of tacit knowledge of axioms fail to satisfy the constraint will help secure our grip on this notion of directness. Such a state can interact with other states only via the states of tacit knowledge concerning the sentences in which the expression corresponding to the axiom figures, because of Frege's insight that a speaker's understanding of a subsentential expression can be manifested only through the use that he makes of whole sentences in which that expression figures: it is always by means of complete sentences that we perform linguistic acts or, more figuratively, make moves in a given language game. Thus, suppose that there is a cognitive state of mine which represents the information that a given predicate, for example, "horse," has such-and-such satisfaction conditions. Suppose also that I hear someone utter the sentence "I have a horse with five legs." Then I might form the belief either that the person in question simply has an understanding of the predicate which differs from mine, or that he has a very rare and unusual sort of horse. But these beliefs can be formed *only* via my implicit knowledge of the meaning of the whole sentence "I have a horse with five legs," because it is only in the context of a whole sentence that a linguistic act involving the predicate can be effected.

So, tacit knowledge of an axiom can never interact directly with other putative intentional states, because it always has to interact with them via states of tacit knowledge of the appropriate meaning-theoretic theorems, in whose causal generation it plays a part.

But now for question (b): Is the fact that a given state fails to satisfy Constraint 2 good grounds for refusing to describe that state as genuinely intentional? Two further questions we might ask in attempting to decide on the plausibility of Constraint 2 are: (1) Is there any good *a priori* motivation for the constraint?, and (2) Does the constraint rule out the states which intuitively ought to be ruled out?

I won't spend a great deal of time on (2). I will limit myself to noting, first, that no genuine belief state can be ruled out by Constraint 2 since I can move from the belief that P to almost any other belief that Q quite simply, by coming to possess the belief that $P \rightarrow Q$ and drawing out the appropriate inference: where the interaction between the belief that P and the belief that $P \rightarrow Q$ needn't take place via any further intentional state causally generated by the belief that P.[5] And, second, that the constraint does appear to rule out at least some of Stich's intuitive examples of subdoxastic states: in the case of Hess's experiment with the retouched photographs, for example, it seems that it is only via their role in generating genuine beliefs that the states representing information about pupil size can interact with other of the agents' propositional attitudes.[6]

So I would tentatively suggest that we can give an affirmative answer to (2). But what about (1)? Why should a state which fails to satisfy Constraint 2 be discounted from being a genuine intentional state? I think this latter question can only be answered after some reflection on the role played by the postulation of intentional states in the rationalistic explanation of human behavior. Some sorts of behavior exhibited by a human agent call for explanation in terms of the beliefs, desires, and other propositional attitudes possessed by that agent, and the use of language is clearly one such kind of behavior. So we attempt rationalistically to explain a person's use of his language by crediting him with a range of intentional states. The crucial point is that once we have credited him with intentional states corresponding to the theorems of a correct theory of meaning for his language, we have everything we need in order to run the appropriate explanation: crediting the speaker with intentional states corresponding to the *axioms* adds nothing whatsoever to the rationalistic explanation of the speaker's behavior provided by ascribing to him intentional states concerning the rules for the use of whole sentences. The explanatory redundancy of the ascription of states of tacit knowledge of the axioms is guaranteed by the fact that they only ever play a part in explaining behavior via states of tacit knowledge of theorems: if it were possible for states of tacit knowledge of axioms to interact directly with other intentional states, then this crucial point about explanatory redundancy could not be made.

So it seems that room can be found for the states corresponding to semantic axioms only within a purely causal explanation of speakers' behavior, and accordingly we can view such states only as purely causal states which play a part in the proximate causal history of the (intentional) states corresponding to the theorems in the semantic theory. Ascribing to speakers intentional states corresponding to various parts of the axiomatic base would simply be to load our explanatory theory with more baggage than is warranted by its explanatory brief: if P only ever "interacts" with other propositional attitudes via a state P* of which it is a causal antecedent, and if describing P as intentional exceeds the explanatory demands on the theory – in the sense that describing P as an intentional state makes *no* contribution whatsoever to that explanation – then it seems that the most that we can claim concerning P is that it is a causal state which plays a part in the proximal causal history of P*.[7]

This seems to rule out Dummett's idea that states of tacit knowledge of the axioms of a semantic theory can be viewed as genuine propositional attitudes. Is there an alternative way of construing the relationship between speakers and the axiomatic base of the semantic theory, and can we still justify the demand for compositionality? Evans's alternative to Dummett attempts to answer these questions, so it is to Evans's discussion that we now turn.

3 Tacit Knowledge and Dispositional States

Evans's discussion proceeds with reference to the relatively simple, and finite, language L consisting of 10 names "a," "b," "c," …, which stand for Harry, John, Bill, …, and 10 predicate expressions "F," "G," "H," …, which stand for happiness, baldness, heaviness,.... L thus has 100 syntactically admissible sentences, each consisting of the concatenation of a name with a predicate.

Suppose that a semantic theorist sets out to find the correct theory of meaning for this language. One constraint is that the theory settled for should have the right *output*: the meaning-specifying theorems which it issues in should be *correct*. Suppose that what the semantic theorist is after is a correct, Davidson-style truth-conditions theory for L. Then we will regard the theory as acceptable if it delivers the following set of truth-conditions specifications:

"Fa" is true-in-L iff Harry is bald
"Fb" is true-in-L iff John is bald
…
"Ga" is true-in-L iff Harry is happy
…
"Oj" is true-in-L iff Michael is anxious.

But then the following problem arises. Call two theories which issue in the same set of truth-conditions specifications *extensionally equivalent*. Then the following two theories for L will be extensionally equivalent:

T1: the *listiform* theory, which has 100 axioms, one for each individual sentence of L (i.e., simply the full list of truth-conditions specifications given immediately above).

T2: the articulated theory consisting of 21 axioms, one for each of the proper names (e.g., "a" denotes Harry), one for each of the predicates (e.g., an object satisfies "F" iff it is bald), and an axiom for the subject-predicate mode of combination (e.g., "a sentence coupling a name with a predicate is true iff the object denoted by the name satisfies the predicate").

T2 is clearly closer in spirit than T1 to the theories which semanticists have in fact been attempting to construct for natural languages; but Wright's demand for a motivation for compositionality can now be stated as follows: given that the constraint that a theory issue in the correct truth-conditions specifications is not by itself sufficiently strong to discriminate in favor of T2, can any further constraints be imposed which will provide a motive for

the preference of T2 to T1? In other words, can there ever be empirically respectable evidence which will discriminate between two extensionally equivalent theories?[8]

Evans suggests the following constraint: the theory should aspire to provide not just the correct truth-conditions specifications, but also a description of the *dispositions* corresponding to each of the expressions for which that theory has a proper axiom. So if we find that speakers have 100 dispositions of the relevant type we will be justified in opting for T1, whereas if we find that they have 20 such dispositions, the acceptance of T2 will be warranted. But what are the dispositions "of the relevant type" alluded to above? In the case of T1, the dispositions corresponding to its primitive expressions (the expressions to which it devotes an individual axiom) are easy to specify: each disposition is simply "a disposition to judge utterances of the relevant sentence-type as having such-and-such truth-conditions" (Evans, 1981, p. 124). T2 is more problematic because its primitive expressions are not whole sentences, but rather proper names and predicate expressions, and it is only sentences which can be said to have truth-conditions. As a consequence, the dispositions corresponding to the primitive expressions of T2 have to be interdefined. Evans suggests characterizing the dispositions as follows:

> We might say that a speaker U tacitly knows that the denotation of "a" is Harry iff he has a disposition such that:
>
> (Πφ)(Πψ) if:
> (i) U tacitly knows that an object satisfies φ iff it is ψ
> (ii) [if] U hears an utterance having the form φ^a, then U will judge that the utterance is true iff Harry is ψ.
>
> Connectedly, we say that a speaker tacitly knows that an object satisfies "F" iff it is bald iff he has a disposition such that:
>
> (Πx)(Πα) if:
> (i) U tacitly knows that the denotation of α is x
> (ii) [if] U hears an utterance having the form F^α, then U will judge that the utterance is true iff x is bald.
>
> In these formulations, "Π" is a universal substitutional quantifier, with variables having the following substitution classes: φ, names of predicate expressions of the (object) language, α, names of names of the (object) language: ψ, predicate expressions of our language (the metalanguage), and "x," proper names of our language. (Evans, 1981, pp. 124–125)

How can we tell whether or not a speaker has the dispositions possession of which constitutes tacit knowledge of T1 or of T2? Evans suggests three sources of empirical evidence.

The first source is connected with Evans's insistence that the notion of a disposition involved in his account has to be taken in a full-blooded way: the ascription of a disposition is not to be regarded merely as a statement that some regularity obtains:

> These statements of tacit knowledge must not be regarded as simple statements of regularity, for if they were, anyone who correctly judged the meanings of complete sentences would have a tacit knowledge of T2. When we ascribe to something the disposition to V in circumstances

> C, we are claiming that there is a state S which, when taken together with C, provides a causal explanation of all the subjects V-ing (in C). So we make the claim that there is a common explanation to all these episodes of V-ing. Understood in this way, the ascription of tacit knowledge of T2 … involves the claim that there is a single state of the subject which figures in a causal explanation of why he reacts in a regular way to all the sentences containing the expression …. The decisive way to decide which [ascription of tacit knowledge] is correct is by providing a causal, presumably neurophysiologically based, explanation of comprehension. With such an explanation in hand, we can simply see whether or not there is an appeal to a common state or structure in the explanation of the subject's comprehension of each of the sentences containing the proper name "a." (Evans, 1981, pp. 125–127)

In addition, we can also examine the patterns of acquisition of knowledge of the meanings of sentences manifested in the linguistic behavior of L-speakers. For example, evidence suggestive of tacit knowledge of T1 would be that even when a speaker has acquired dispositions to judge correctly of the truth-conditions of Ga and Fc, he is not thereby (in the absence of further training and exposure) disposed to judge correctly of the truth-conditions of Gc. Evidence suggestive of tacit knowledge of T2 would be that he is, under the same conditions, so disposed.[9]

Further evidence is provided by the patterns of loss of knowledge of meanings exhibited in speakers of L. If such a speaker is initially competent with each of the 100 sentences of L and if, by knocking out his competence with, say, Hd, we thereby disturb his competencies with all other sentences containing the expressions "H" and "d," then tacit knowledge of T2 will be ascribable. But if the other competencies remain undisturbed by the speaker's loss of competence with Hd, then the ascription of tacit knowledge of T1 will be in order.

It seems, then, that we have found an empirically respectable way of deciding which of T1 and T2 should be accepted for the language L. It is perhaps worth noting that at this stage the central idea underlying Evans's account seems to be the following: the derivational structure of a theory of meaning (the canonical routes from its axioms to its theorems) should in some sense reflect the causal structure found among the competencies of the speakers of the language under scrutiny (the causal routes leading from the dispositions associated with the language's names and predicates to the intentional states associated with the whole sentences of the language). In the remainder of this chapter I shall elaborate upon and question the constraint motivated by this central idea.

4 Wright's Attack on Evans

In this section I outline three criticisms that Wright has raised against Evans's dispositionalist account of tacit knowledge of semantic axioms, and the responses that have been offered by Martin Davies on Evans's behalf. I shall argue that the responses offered by Davies to two of Wright's criticisms are unsuccessful as they stand, and sketch my own alternative defense of Evans against them. I will then show how Davies's response to the third objection is plausible as it stands.

Wright's first objection to Evans concerns characterization of the dispositions which constitute tacit knowledge of T2. We can see from the quotations above that the dispositions corresponding to the names and predicate expressions of L have to be interdefined, that is, the dispositions which constitute tacit knowledge of the denotation conditions of the

proper names of the language are defined in terms of tacit knowledge of the satisfaction conditions of L's predicate expressions; and the dispositions which constitute tacit knowledge of the satisfaction conditions of the predicates are defined in terms of tacit knowledge of the denotation conditions of L's proper names. Why is this a problem? As Wright puts it, "to characterize a disposition ought to be to characterize both what it is a disposition to do and the circumstances under which it will be manifest" (Wright, 1986, p. 233). Suppose, for example, that we are trying to give a dispositional account of ductility, and that we come up with: X is ductile iff the observable phenomena $c_1, \ldots, c_n$ occur under background circumstances C. Suppose further that the conditions C include the possession by X of the additional dispositions $d_1, \ldots, d_k$. Wright's point is that if, in characterizing the manifestations distinctive of some one of the further dispositions d_i, say, we have to refer to background circumstances *which include the assumption that X is ductile*, we will have said thereby *nothing whatsoever* as to what ductility consists in: we will simply have failed to say what ductility is.

This point seems to me to be fundamentally correct, and it is easy to see how it applies to Evans's account of tacit knowledge of T2. Take the disposition which constitutes tacit knowledge of the denotation of the name "a." What we are after in characterizing this disposition is something of the form: X tacitly knows that the denotation of "a" is Harry iff observable phenomena $c_1, \ldots, c_n$ occur under background conditions C. In this case the background conditions include the possession by X of the further dispositions $d_i, \ldots$ = tacit knowledge of the satisfaction conditions of certain of the predicate expressions of L. But a characterization of the distinctive manifestations of the d_i's is possible only if we make reference to background conditions in which X is assumed to have tacit knowledge of the denotation conditions of the names of L, and it is precisely *this* species of tacit knowledge which we are trying to explicate. So our account turns out to be viciously circular, and we fail altogether in our attempt to say what tacit knowledge that the denotation of "a" is Harry consists in.

Wright himself is not pessimistic about the possibility of a solution to this problem:

> I offer the point more as something which someone who wished to advance Evans's account should say something about than as an objection. Perhaps a more sophisticated account of the notion of a disposition would remove the worry; my own suggestion would be that Evans's proposal should have proceeded by reference to states of a different sort – his real interest, after all, is in the underlying 'categorical' bases. (Wright, 1986, p. 233)

And Davies subsequently offers what seems to be a respectable way around the trouble threatened by Evans's characterization. Davies suggests that we cast our account of tacit knowledge in terms of "underlying explanatory states," rather than in terms of dispositions; instead of defining tacit knowledge in terms of the dispositions a speaker has concerning truth, satisfaction and denotation conditions, we define it in terms of the states which make up the "categorical bases" underlying those dispositions.[10] The speaker with tacit knowledge of T2 will not now be characterized as having 20 dispositions defined *à la* Evans, but as being the bearer of 20 *causal explanatory states*, each of which is the basis of one of those dispositions. This allows us to state the constraint that was breaking through the clouds at the end of §3:

> If, and only if, a speaker who has dispositions to judge correctly of the truth-conditions of $S_1, \ldots, S_n$ is thereby (and without any further training or exposure) disposed to judge

> correctly of the truth-conditions of S, should the semantic resources sufficient for the canonical derivation of truth-conditions specifications for S_1, …, S_n be sufficient for the canonical derivation of a truth-condition specification for S.

Under our first revision of Evans's account in terms of underlying states, this becomes what Davies terms the *mirror constraint*:

> If, and only if, the operative states implicated in the causal explanation of a speaker's beliefs about the meanings of S_1, …, S_n are jointly sufficient for a causal explanation of his belief about the meaning of S, should the semantic resources sufficient for a canonical derivation of truth-conditions specifications for S_1, …, S_n be sufficient for the canonical derivation of a truth-condition specification for S.

However, I have the following worry about whether this does satisfactorily avoid Wright's problem concerning interdefinability and vicious circularity: If our only means of *individuating* the categorical bases underlying the dispositions is via the dispositions which they underlie, then doesn't the problem simply carry over into the revised account in terms of causally operative states? Is it possible to characterize the causally operative state which underlies my disposition concerned with the denotation condition of the name "a" *without* referring to the causal states underlying the disposition I have connected with the satisfaction conditions of L's predicates? If not, and if this holds vice versa, then I suggest that we have again failed to say what tacit knowledge that the denotation of "a" is Harry consists in, because we will have failed to individuate the causal state, possession of which allegedly constitutes that tacit knowledge. So we are faced with the following dilemma: either we must provide an account of how the operative states can be individuated without reference to the dispositions which it is claimed they underlie – which account is at present lacking – or, on the other hand, the problem that arose for Evans's account arises again for Davies's proposed revision.

Is Wright's objection, then, fatal to Evans's account? We would be over-hasty in concluding that it is: Davies's switch to talk of underlying causal states and categorical bases, indeed, does nothing to remove the circularity which Wright focuses on, but how *vicious* is that circularity? I will suggest that the circularity here will infect any constitutive account of the mastery of individual sub-sentential expressions, no matter whether that account is couched in terms of dispositions, underlying causal states, or anything else we care to choose. This should raise our suspicions about whether circularity can be regarded as a *defect* in such an account.

Any account of what competence with a name consists in will have to contain resources sufficient for an account of what competence with the sentences containing that name consists in, since it is only in the use of whole sentences that competence with the name can be manifested. This means that we will also require an account of what competence with predicate expressions consists in; and when we try to give this latter account – an account of what understanding the sentences containing the predicates consists in – we find ourselves back at the point we started out from, requiring an account of what competence with names consists in. Thus, *any* account of what competence with a name consists in requires an account of what competence with predicate expressions consists in, and vice versa.

This points to the proper line of response to Wright's objection. Isn't it the case that something analogous to this interdefinability property is possessed by beliefs and desires?

Intentional action requires both beliefs and desires to be present, and, more generally, beliefs, desires, and propositional attitudes are ascribable to an agent only in systems, and not individually. When we attempt to give, say, a constitutive account of the belief which partially rationalizes a certain action, we stand in need of a similar account of the appropriate desire, and vice versa. But we would not take this to signal the impossibility of providing a constitutive account of either belief or desire; rather, the conclusion drawn is that the relationship between the beliefs, desires, and the behavioral facts which ground their ascription is irreducibly *holistic* (see Chapter 15, HOLISM). How, then, do we say what beliefs and desires are? I think, roughly speaking, that there are two components to this. First, by showing how the propositional attitude ascriptions relate *to each other* by giving the *a priori* principles which constrain the relations *between* the various sorts of propositional attitude; and second, by giving the interpretative principles which link the propositional attitudes holistically to the behavioral facts which ground their ascription (see Fricker, 1981). In summary, we individuate a propositional attitude not by picking it out individually, but by giving its place in the network of propositional attitudes which form part of any agent's mental armory. So the fact that we *can't* pick out such states in isolation from the entire network in which they occur needn't give us too much cause for concern.

I suggest that an analogous point is available in the case of states of tacit knowledge. All the interdefinability focused on by Wright shows is that tacit knowledge, too, has to be ascribed in a holistic fashion. We do not give an account of what tacit knowledge of, say, a name "a" consists in, apart from an account of what constitutes tacit knowledge of the complete axiomatic base: and we give such an account by delineating the constraints which govern the ascription of tacit knowledge of the axiomatic base *as a whole*. This is where the mirror constraint has a crucial part to play: faced with a semantic theory T, we decide whether or not a speaker should be ascribed tacit knowledge of T by seeing whether the theory meets the mirror constraint with respect to that speaker; in other words, by seeing whether the derivational structure *of the whole theory* is isomorphic in the relevant sense to the causal structure found in that speaker's overall competence. Just as we give an account of what beliefs are by giving their location within a wider network of propositional attitudes, we give an account of what tacit knowledge is by showing how the causal states in question are located in a wider causal structure: having given the structure, we need say nothing more about the composition of the individual states. The mental, unlike the metallurgical, is essentially holistic.[11]

I now move on to look at Wright's second objection to Evans's account of tacit knowledge. I will argue that although the solution which Davies proposes is a good solution to a problem which Evans perhaps ought to have taken account of, it simply fails altogether to engage with Wright's objection in the deeper form in which he originally raised it. I will then show how Davies ought to have responded to Wright's deeper objection.

Davies summarizes the objection thus:

> The second objection relates to the account of tacit knowledge as a certain kind of causal structure. Suppose that a subject knows (tacitly or in the ordinary sense) what the various sentences of L mean; and suppose that underlying those pieces of knowledge there is indeed a causal structure of the kind which, on Evans's account, is required for tacit knowledge of T2 – the articulated theory. Wright asks why such a subject would not be at least as well described by a two-part theory. The first part would be the *semantic* theory T1 – the listiform theory; the second part would be 'some appropriate hypotheses of a *non-semantic* sort, about the presumed

> causal substructure of the dispositions which T1 describes'. Why, in short, does mere *causal* structure justify articulation in a *semantic* theory? (Davies, 1987, pp. 443–444).

The suggested problem seems to be that not all attributions of causal explanatory structure will be pertinent to the ascription of tacit knowledge to the speaker concerned; and in order to bring this point home Davies provides an example of a case in which "a pattern of breakdown is intuitively misleading as to the attributability of tacit knowledge … [but where] … the evidence is not obviously misleading as to the presence of some kind of causal structure" (Davies, 1987, p. 451).

Consider the speaker C who has a language system which performs derivations in an explicit representation of the semantic theory T1 – the matrix in Figure 12.1 is supposed to show how the representations of the 100 axioms of T1 are arranged, and each of its elements represents an information storage unit. Now we elaborate the example somewhat and suppose that in order to function properly the individual units of the matrix have to be supplied with certain nutrients, which flow through the matrix in channels. Suppose also that there are two types of nutrient X and Y, that the X nutrient flows through the matrix in 10 channels X_a, …, X_j "each of which serves the ten storage units for the ten sentences containing a single name," and that in a similar fashion the Y nutrient flows in 10 channels Y_F, …, Y_O "each of which serves the ten storage units for the ten sentences containing a single predicate." The supposition crucial for the example is that each of the storage units will *fail* to function if it doesn't get its supply of *each* of the nutrient types, so that "failure of a unit prevents nutrient flow through at least one of the channels serving that unit."

The difficulty should now be clear: we want to say that if the speaker has tacit knowledge of any theory then he must have tacit knowledge of T1, but the patterns of breakdown likely to occur in his linguistic behavior will suggest the ascription of tacit knowledge of T2. For example, if his competence with Gg is knocked out, because of the implications this has for the channels of nutrient flow, his competencies either with all other sentences containing G or with all other sentences containing g, or both, will be knocked out also.

Figure 12.1

Davies's first point seems basically correct: not all causal structure will be germane to the attribution of tacit knowledge, so we need some account which will enable us to discriminate between causal structure that is thus relevant, and causal structure that is not. Nutritional structure is causal structure, but is intuitively irrelevant to the ascription of tacit knowledge. Why is this so? Davies suggests that this is because "the causal explanatory structure in the example is in no way *sensitive* to the *information* stored in the units," and that this lack of sensitivity is manifested in the fact that the patterns of *revision* of semantic beliefs are unlikely to follow the patterns of semantic decay: "we do not expect that *revision* of C's belief about the meaning of 'Fa' would go hand in hand with corresponding revisions of his beliefs about other sentences" (Davies, 1987, p. 453). So we need to revise our account of causal structure, and with it the mirror constraint, in such a way that the required sensitivity to informational content is introduced. In accordance with the remarks above, this is introduced via the notion of revision, so that the mirror constraint is modified thus:

> If, and only if, the operative states implicated in the causal explanation of a speaker's beliefs about the meanings of S_1, …, S_n are jointly sufficient for a causal explanation of his belief about the meaning of S; *and* those first states together with the revision of the speaker's belief about the meaning of S provide an explanation of the speaker's corresponding revisions in his beliefs about the meanings of S_1, …, S_n, should the semantic resources sufficient for the canonical derivation of truth-conditions specifications for S_1, …, S_n be sufficient for the canonical derivation of a truth-condition specification for S.

But does the introduction of the notion of sensitivity to information really solve the difficulty which Wright raised? I want to suggest that it does not, and that in fact Davies has misunderstood the character of Wright's objections here.

Wright's problem was *not* that some patterns of causal structure were irrelevant to tacit knowledge ascriptions, but that *even if* we could find a good constitutive account of tacit knowledge in which some form of causal structure was relevant to its ascription, this still would not justify articulation in the derivational structure of a semantic theory. Even if we *grant* the assumption that certain of the causal interrelations amongst speakers' competencies *are* worth describing, the objection raised is that we needn't run the risk of having the structure of these interrelations reflected indirectly via the derivational structure of a theory of meaning. Such structure could equally well be described (in the case of language L) by a listiform theory like T1, supplemented with a rider along the following lines: speakers are generally able to understand novel utterances provided they only involve familiar semantic primitives, and changes in their semantic beliefs about a sentence tend to be associated with changes in their semantic beliefs about all sentences containing one or more of the semantic primitives figuring in that sentence. More *detail* can then be obtained via the recursive syntax which was initially wedded to the listiform semantic theory. It might be worthwhile to pause briefly and investigate precisely how the relevant detail can be brought to light.

Wright suggests that the recursive *syntax* will provide this detail on the condition that it itself satisfies the mirror constraint. Now what does it mean to say that a syntax satisfies the mirror constraint? I suggest the following reconstrual of the mirror constraint for syntactical theories:

> If, and only if, the causal states implicated in the causal explanation of a speaker's beliefs about the meanings of S_1, …, S_n are jointly sufficient for a causal explanation of his belief about the meaning of S; *and* those first states together with the revision of the speaker's belief about the meaning of S provide an explanation of the speaker's corresponding

> revisions in his beliefs about the meanings of S_1, …, S_n, should the syntactic resources sufficient for the canonical derivation of well-formedness specifications for S_1, …, S_n be sufficient for the canonical derivation of a well-formedness specification for S.

If a syntactical theory satisfies this then *its* derivational structure (the canonical routes from its axioms to its specifications of well-formedness) will mirror with at least as much clarity the causal structure of speakers' competencies which was initially mirrored in the derivational structure of the semantic theory. It is important to note that this objection holds good even where the causal structure *is* sensitive to the informational content stored in the units of the representation of a semantic theory. Davies betrays his misunderstanding of this point in the following passage:

> It may be that by Wright's lights, no refinement of the notion of causal structure could ever justify the idea that a *semantic* theory should mirror that structure. But, to the extent that any refinement ensures that the salient causal structure can be described as an information-processing structure, this extreme view will be hard to sustain. (Davies, 1987, p. 454)

I disagree with this: even if we find that the salient causal structure can in fact be described as an information-processing structure, the objection still stands. The problem is not one of answering the question of how *causal* structure justifies articulation in a semantic theory, but rather of answering the question of how causal structure justifies articulation in a *semantic* theory.

Thus, notwithstanding the fact that Davies's revised account provides a useful sharpening-up of the notion of causal structure considered as relevant to the attribution of tacit knowledge, I would suggest that that revision leaves Wright's objection, properly read, completely untouched.

How, then, can we deal with Wright's objection? Wright's thought was that causal structure can be reflected by a purely syntactical – that is, non-semantic – theory, and that therefore some additional reasons have to be provided to ground the preference for reflection in theories of meaning. I think we can undercut Wright here by *denying* that he has shown how to reflect the salient causal structure in a non-semantic theory. Let's look more closely at the conjunction: listiform semantic theory plus syntactical theory which meets the mirror constraint. The latter part of the conjunction will reflect the same causal structure as any semantic theory which satisfies the mirror constraint. But is it really *non-semantic* in nature? I would say that it is not – that if we stipulate that the syntactical theory must meet the mirror constraint (as modified to apply to such theories) then it is no longer *purely* syntactical. Agreed, the theorems which form the output of this theory are concerned solely with the well-formedness or otherwise of the sentences of the language. But what a theory is *about*, what *sort* of theory a given theory *is*, is determined not only by the content of the sentences which make up its output, but also by the constraints in accordance with which that output is generated. Suppose, for example, we have a theory A whose output consists of sentences detailing the amount of money possessed by a sample of 100 Scottish women, and a theory B whose output consists of sentences detailing the amount of money possessed by a sample of 100 people, but which has been constructed in accordance with the constraint that the people included in the sample space should all be Scottish women. Then, even though theory B's output is couched in pronouncements of the form "Person X has £x" which feature no mention of Scotland or women, there is a clear sense in which that theory is still *about* Scottish women. To get back to the linguistic case, we should note that the mirror constraint is a *semantic* constraint – it makes reference to beliefs about the *meanings* of sentences and to relations that obtain between these beliefs. So, any theory

which is required to satisfy the mirror constraint will be a semantic theory to the extent that it will encode semantic information, including, despite appearances, any theory whose output mentions only the grammaticality of the language's sentences.

I thus deny that Wright has shown how the relevant causal structure can be reflected by a non-semantic theory: what he has given us is, in fact, an account of how that structure can be reflected in another *semantic* theory. Indeed, it is perhaps misleading even to speak of *another* semantic theory: just as the theory B above seems to be little more than a *reformulation* of the theory A, given the extensional equivalence of T1 and T2, the conjunction of T1 with a recursive "syntax" which is really partially semantic seems to me to be little more than a reformulation of the explicitly semantic T2.[12]

I now look at the third objection which Wright raises against Evans. According to Evans's original account, the job of the theory of meaning is to describe the dispositions which speakers have, corresponding to each of the expressions for which that theory provides a separate axiom. But if this is *all* that the theory is meant to do, then the twenty-first axiom of T2 – the compositional axiom – ought to be redundant, because someone who only has the dispositions described by the other 20 axioms will thereby be disposed to judge correctly of the truth-conditions of the sentences of L. This is again a consequence of the fact that the dispositions connected with the names and predicates are interdefined. However, without the compositional axiom the theory T2 will be paralyzed: it will be impossible to derive any truth-conditions specifications for the sentences of L. So "Evans has not shown how we are to construe an articulated semantic theory as a description of speakers' dispositions" (Davies, 1987, p. 444).

The way out of this difficulty is again to switch from talk of dispositions to talk of the states underlying those dispositions, and of the reflection of causal explanatory structure via the satisfaction of the mirror constraint. The job of the theory of meaning is now viewed not as the description of dispositions, but as the reflection of a certain sort of causal structure. There is, then, no obstacle preventing the theory T2 from satisfying the mirror constraint, and hence no obstacle to its reflecting the structure in question and thus doing its proper job.

Let me try to clarify this point with the aid of one of Davies's examples. Consider another semantic theory T3, which has the same axioms as T2 for the proper names of L, but differently styled axioms for its predicates. These axioms will instead be of the form:

> A sentence coupling a name with the predicate "F" is true iff the object denoted by that name is bald.

As Davies puts it, "What T3 does is to parcel out the content of T2's compositional axiom among the ten predicates of the language" (1987, p. 445), so that T3 is not open to Wright's objection even when we take the Evans line about the description of dispositions. More importantly, when we take the line in terms of causally operative states and reflection of causal structure, it seems that there is nothing to choose between the ascription of tacit knowledge of T2 and the ascription of tacit knowledge of T3. To see this, define a relation of *DS-equivalence* (equivalence in point of derivational structure) on theories of meaning as follows:

> Two (extensionally equivalent) theories Tk and Tm are DS-equivalent iff, for any sentences S_1, …, S_n, S: the semantic resources in Tk which suffice for the canonical derivation of truth-conditions specifications for S_1, …, S_n suffice also for the canonical derivation of a truth-condition specification for S if and only if the semantic resources in Tm which suffice

for the canonical derivation of truth-conditions specifications for S_1, …, S_n suffice also for the canonical derivation of a truth-condition specification for S.

Then it turns out that T2 and T3 are DS-equivalent, for "although T2 has an extra axiom relative to T3, the use of this resource in T2 is constant across all derivations of meaning-specifications for whole sentences" (Davies, 1987, pp. 446–447). I'll clarify this by means of an example. In T2 the semantic resources sufficient for the derivation of a truth-condition specification for "Ga" and "Fb" are sufficient also for the derivation of a truth-condition specification for "Fa":

Ga	(1)	"a" denotes Harry	(axiom for "a")
	(2)	an object satisfies "G" iff it is happy	(axiom for "G")
	(3)	a sentence coupling a name with a predicate is true iff the object denoted by the name satisfies the predicate	(compositional axiom)
	(4)	"Ga" is true iff Harry is happy	(from (1), (2), and (3))
Fb	(1)	"b" denotes John	(axiom for "b")
	(2)	an object satisfies "F" iff it is bald	(axiom for "F")
	(3)	a sentence coupling a name with a predicate is true iff the object denoted by the name satisfies the predicate	(compositional axiom)
	(4)	"Fb" is true iff John is bald	(from (1), (2), and (3))
Fa	(1)	"a" denotes Harry	(axiom for "a")
	(2)	an object satisfies "F" iff it is bald	(axiom for "F")
	(3)	a sentence coupling a name with a predicate is true iff the object denoted by the name satisfies the predicate	(compositional axiom)
	(4)	"Fa" is true iff Harry is bald	(from (1), (2), and (3))

We can see that the resources used in T2 in the derivations of the specifications for "Ga" and "Fb" were the axioms for "a," "b," "F," "G," and the compositional axiom. These give all we need in order to derive a specification for "Fa." Now, because of the way the compositional axiom is built into the axioms for the predicates in T3, the same thing holds in T3. Witness,

Ga	(1)	"a" denotes Harry	(axiom for "a")
	(2)	a sentence coupling a name with the predicate "G" is true iff the object denoted by the name is happy	(axiom for "G")
	(3)	"Ga" is true iff Harry is happy	(from (1) and (2))
Fb	(1)	"b" denotes John	(axiom for "b")
	(2)	a sentence coupling a name with the predicate "F" is true iff the object denoted by the name is bald	(axiom for "F")
	(3)	"Fb" is true iff John is bald	(from (1) and (2))
Fa	(1)	"a" denotes Harry	(axiom for "b")
	(2)	a sentence coupling a name with the predicate "F" is true iff the object denoted by the name is bald	(axiom for "F")
	(3)	"Fa" is true iff Harry is bald	(from (1) and (2))

Here the resources used in the derivations of specifications for "Ga" and "Fb" were the axioms for "a," "b," "F," and "G." And again, these give us all we need in order to derive a specification for "Fa." We could do this again for all the appropriate sentences of L, and this would amount to a conclusive proof of Davies's assertion that T2 and T3 are DS-equivalent.

We thus find ourselves in the following position: because of the DS-equivalence of T2 and T3, either both theories satisfy the mirror constraint for a given speaker, or neither does; so that the 5% difference – the difference between the 20 axioms of T3 and the 21 axioms of T2 – *doesn't* in fact matter. Given that we are not concerned with the description of dispositional states apart from their position in a causal web whose structure we are concerned to reflect, the fact that we can describe that causal structure in causal theories which do not devote an individual axiom to name–predicate concatenation is innocuous: it does not vitiate its reflection in theories which *do* contain such an axiom.

However, as Davies realizes, there is now another objection in the offing. Suppose we are trying to decide whether a given articulated semantic theory satisfies the mirror constraint with respect to a particular speaker of L. Suppose also that that speaker revises his belief concerning "Fb" from "John is bald" to "John is baldish." In accordance with the mirror constraint, we will check whether he revises his beliefs about "Fa," "Ga," and "Gb" *correspondingly*. But what counts as the *corresponding* revision of, say, "Gb"? Is it the null revision, which leaves the speaker with the belief that "Gb" means that John is happy, or is it the revision which leaves him with the belief that John is happyish? No one of these answers seems to be uniquely correct, and according to Davies this latent indeterminacy is a time-bomb which threatens the stability of his proposed account of tacit knowledge. But this threat seems to dissipate somewhat when we note that the indeterminacy can in fact be resolved "according as we look at the semantic properties of a language through the grid of one theory rather than the other" (Davies, 1987, p. 459). Precisely how this resolution is achieved can be seen from the following quotation from an earlier paper of Davies's – to say that the revision of the semantic belief concerned with S_i corresponds (considered from the viewpoint of a particular semantic theory) to the revision in the semantic belief concerned with S is to say that:

> If A were to revise his belief about the meaning of S in that respect of the meaning which the semantic theorist discerns as a deductive consequence [in the semantic theory in question] of the presence in S of the syntactic item Γ assigned the semantic property Δ, and if what A believed about the meaning of S as the result of this revision were to be the deductive consequence of a revision of Δ to Δ^*, then A would revise his belief about the meaning of S_i (and the meanings of any other sentences containing Γ) in such a way as would be the deductive consequence (in the theory in question) of the assignment to Γ of Δ^* rather than Δ. (Davies, 1981b, p. 149)

Given this, we can now say which revisions merit the ascription of tacit knowledge of T2, and which merit the ascription of T3. And it seems that these will not coincide:

> If we consider T2, then there are two possible changes in the proper axioms, each of which would result in "Fb" being assigned the meaning that John is baldish. A change in T2's axiom for "F" has one pattern of consequences: a change in the 21st axiom – the compositional

> axiom – has a different, and more extensive pattern of consequences. If we consider T3, on the other hand, then there is only one possible change to the proper axioms which would result in "Fb" being assigned the meaning that John is baldish. (Davies, 1987, p. 459)

So, our original account, in which the ascription of tacit knowledge of T2 simply was ascription of tacit knowledge of T3, and vice versa, will have to be revised in such a way as to take this into account. For consider the following two speakers A and B

> [f]or whom, a form of the language of thought hypothesis is true. For these speakers, language comprehension – in particular, the assignment of meaning to sentences – is a matter of derivations in a semantic theory explicitly represented in a special purpose language processing system. Suppose that speaker A conducts on his inner blackboard derivations in theory T2, while speaker B conducts derivations in theory T3 … For the purposes of tacit knowledge ascriptions speakers A and B are grouped together. (Davies, 1987, pp. 447–448)

But now:

> Just as theory T2 with its 21 axioms provides an extra locus of content sensitivity over theory T3 with its 20 axioms, so the causal explanatory structure in speaker A provides an extra locus of systematic revision over the causal explanatory structure in speaker B. So, not altogether surprisingly, it is speaker A – conducting inner derivations in theory T2 – who meets the condition for tacit knowledge if the indeterminacy is resolved by looking at the language through the grid of T2. And it is speaker B who meets the condition if the indeterminacy is resolved by looking at the language through the grid of theory T3. (Davies, 1987, p. 459)

What is going on here? The suggestion is that *only if* we have a one-to-one correspondence between the axioms of a theory of meaning and the explanatory loci of systematic revision which go towards making up the causal explanatory structure in a speaker can we spell out satisfactorily the notion of systematic revision amongst the implicit semantic beliefs that constitute that speaker's linguistic competence. For if the axioms for the language's expressions and the speaker's competencies with those expressions correspond with each other one by one, then since "for each axiom or rule, the required notion of *systematic revision* can be spelled out in a quite determinate way," similarly, determinate sense can be made of the notion of systematic changes in the nature of the speaker's competencies, that is, in his revisions of his semantic beliefs. If this is correct then the 5% difference *will* matter – A will be viewed as having tacit knowledge of T2 (and not of T3) while B will be viewed as having tacit knowledge of T3 (and not of T2).

Although I am suspicious of the details of Davies's example of the speakers A and B – it is unclear, for instance, whether A really has the 21 causal explanatory states required for tacit knowledge of T2 (what state now corresponds to the compositional axiom?), and witness the hardly uncontroversial assumption about the language-of-thought hypothesis – I think we can accept that he has provided a good argument to the effect that a speaker with causal states underlying Evans's dispositions can only be ascribed tacit knowledge of T3 and not T2, because in the latter case we would have no means of resolving the indeterminacy which surrounds the possible revisions which such a speaker could make in his semantic beliefs. However, as Davies himself points out, this amounts only to a minor revision, and certainly not to a wholesale rejection, of the account of tacit knowledge which has its roots in Evans's suggestions. As Davies puts it, "the form of Evans's original proposal shines through" (1987, p. 461).

5 The Mirror Constraint and Understanding Novel Utterances

Can the imposition of the mirror constraint help us understand speakers' capacities to understand novel utterances, provided they include only familiar semantic primitives and modes of construction? Suppose that a speaker can come to understand S after exposure to the sentences S_1, …, S_n, that loss of competence with S occasions loss of competence with at least some of S_1, …, S_n, and that a revision of a speaker's belief concerning the meaning of S occasions corresponding revisions in his beliefs about the meanings of each of S_1, …, S_n. Then, on the basis of this evidence we shall claim that: the operative states implicated in the causal explanation of the speaker's beliefs about S_1, …, S_n are jointly sufficient for a causal explanation of his belief about the meaning of S, and those first states, together with his revision of his belief about the meaning of S, are sufficient for an explanation of the corresponding revisions in his beliefs about the meanings of S_1, …, S_n. Of course, to make such a claim is not yet to *provide* the causal explanation alluded to, so that we are still left with the question: How is it possible that the operative states implicated could be thus sufficient? It is precisely this question that is answered by showing how the semantic resources sufficient for the canonical derivation of meaning specifications for S_1, …, S_n are sufficient for the canonical derivation of a meaning specification for S, by the provision of a semantic theory in which they are so sufficient. That is, the move from the operative states to the belief about the content of the novel utterance is viewed as being explained by the provision of a theory which generates, on the basis of the information represented by the relevant operative states – represented by the axioms of the theory – a meaning-specifying theorem which gives the content of the novel utterance in question. So, the provision of a compositional theory of meaning is supposed to make explicable the notion that a speaker could come to form an implicit belief about the content of a novel utterance on the basis of a pre-existing set of causally operative states, because the route from the operative states to the belief about content is reflected by the derivational route from the axiomatic base of the semantic theory to the appropriate meaning-specification. Thus, the construction of a compositional semantic theory, and the notions that speakers might have, in the requisite sense, tacit knowledge of such a theory, is supposed to help answer the question as to how it is possible for speakers to understand utterances of previously unencountered sentences.[13] Davies thus goes beyond Evans, who claims that "the notion of tacit knowledge of a structure reflecting theory of meaning, explained as I have explained it, cannot be used to explain the capacity to understand new sentences" (1981a, p. 134). I shall return to this difference between Evans and Davies in the final section.

6 Wright's Proposal

In addition to the objections responded to in §4, Wright complains that whereas the account of tacit knowledge given by Evans – and by implication, the development of that account via the imposition of Davies's mirror constraint – requires the semantic theorist to pay attention to empirical facts about language acquisition, loss, and revision, *actual* semantic theorizing seems to have proceeded in happy ignorance of such facts. Loath to conclude that the right conception of the semantic theorist's task "has not greatly impinged upon the consciousness of workers in the field," Wright proposes an alternative account of what theorists of meaning ought to be doing, which is claimed to harmonize better with their actual *modus operandi*. In this section I briefly outline Wright's alternative proposal, and argue that it

presupposes, rather than undercuts, the Evans–Davies account which proceeds via the imposition of the mirror constraint.

Speakers are able to understand novel utterances provided they include only familiar semantic primitives; and the semantic theorist's task is to give an answer to the question, "How do they do it?" Wright sees this question as dividing into two sub-questions: (a) How is it possible for there to be a device which could, when fed with information concerning the visible or audible structure of a sentence, process that information in such a way that a theorem about the meaning of the sentence is generated? and (b) How is it possible for such a device actually to be embodied in normal, competent speakers of a natural language? Question (a) is conceived of as being answerable *a priori*, independently of the empirical evidence upon which Evans and Davies lay so much stress: it will have been answered when a suitable "computer program" has been written, the writing of which will not demand elevation from the armchair. Wright thus thinks that if we view semantic theorists as attempting to answer question (a) in the manner he describes, the discrepancy between the account of what their project is, and what they actually do, will vanish. And he views the provision of an answer to (a) as an essential prerequisite for any attempted answer to (b):

> The sort of understanding of the actual capacities of speakers which is called for would be achieved exactly when enough was known about them to enable us to understand how in detail they embody such a device. And, of course, there can be no such understanding before we have formed the appropriate theoretical conception of the powers which the device must have. Doing that requires writing the computer program. (Wright, 1986, p. 236)

However, it seems to me that Wright has overlooked something crucial here. Given that we are interested in answering the question "How do *they* do it?" even after (a) and (b) have been answered there remains the further question: (c) Do they, in reality, embody the device whose theoretical powers the computer program describes? An affirmative answer to this question is crucial if the answers given to (a) and (b) are to have any explanatory value: an account of the theoretical powers of the device and an account of how it might be *possible* for speakers to embody it will have no explanatory value as an answer to the question "How do they do it?" if they do not actually embody the device in question. Questions (a) and (b) together tell us how it *could* be done, but what we are really after is an account of how it *is* done, and for this we need an answer to (c). And, of course, the provision of an answer to (c) is an empirical matter, dependent on the sort of empirical evidence concerning language acquisition and loss Evans and Davies focus on: whether or not a speaker actually does embody a particular information-processing mechanism is a matter which is amenable to empirical investigation. We will not view a particular speaker as embodying a particular information-processing mechanism unless the derivational structure of that mechanism is isomorphic to the causal explanatory structure, the existence of which is suggested by the appropriate sorts of empirical data.

So if semantic theorists are out to answer the question "How do they do it?" of our capacity to understand novel utterances, they are at some point going to have to pay attention to empirical detail. The question is, of course, where? Two broad answers to the question suggest themselves. The semantic theorist could begin to pay attention to such detail at the final stage of his enterprise: having written the appropriate computer program, and having shown – somehow or other – that it is possible for it to be embodied in speakers, he could then *go on* to ask whether or not they actually do embody it. And it is at this final stage that the usual sources of empirical evidence will be crucial. The semantic theorist would thus be

attempting to answer the questions (a), (b), and (c) in a straightforwardly linear fashion. But it is clear that this could be an extremely inefficient way of going about things: once answers to (a) and (b) have been provided, there is no guarantee that the required affirmative answer to (c) will be forthcoming. The semantic theorist could write out his program, argue that it is possible for the information-processing device to be embodied in actual speakers, and then discover – to his horror – that it is in fact *not* actually embodied. And this could happen time and time and time again. Of course, he might get an affirmative answer to (c) on one of his early attempts after all; but it is clear that if he is proceeding in the linear fashion described, this could only have the status of a happy accident.

An alternative, and much more efficient, way of proceeding would be to write the computer program out as before, but this time in accordance with empirical constraints which ensure that, once (a) and (b) have been answered, no obstacle remains to the production of an affirmative answer to (c). In effect, this involves writing the computer program – constructing the theory of meaning – in accordance with some constraint along the lines of the mirror constraint. The semantic theorist is thus still viewed as attempting to answer the questions (a), (b), and (c), but no longer in the simple linear fashion described above. We answer (a) and (b) subject to the constraint that there is an affirmative answer to (c) via the imposition of something like the mirror constraint, and we are justified in so doing because without an affirmative answer to (c) the answers to (a) and (b) will have no explanatory value as answers to the question, "How do they do it?" There is no point in writing a program describing the theoretical powers of an information-processing device which we do not embody if the whole aim of the enterprise is to achieve an understanding of how *we* can understand novel utterances.[14]

My conclusion is thus that, far from providing an account of the semantic theorist's task which does not involve the imposition of the mirror constraint, Wright's suggestions, in the end, only serve to highlight the need for the imposition of that very constraint.[15]

7 Tacit Knowledge and Rule-Following

In the above, I have been attempting to defend the suggestion that the construction of theories of meaning should be subject to Davies's mirror constraint. But there is at least one major problem outstanding which anyone wishing to embrace the account I have defended would have to face up to. I cannot do more than briefly mention this problem here. It stems from the fact that our account attempts to give an explanation of language mastery – in particular of the capacity to understand novel utterances – in *cognitive-psychological* terms. In Wright's words, it is an ability we are conceived to have

> because we are appropriately related to a finite body of *information* which may be inferentially manipulated in such a way as to entail, for each novel string on which we can exercise our "linguistic-creative" power, appropriate theorems concerning its grammaticalness and content,

which commits us to

> the picture of language as a kind of syntactico-semantic mechanism, our largely unconscious knowledge of which enables us to compute the content which, independently and in advance

> of any response of ours, it bestows on each ingredient sentence … [and in which] the mechanism does the generating and the competent adult keeps track of what (and how) it generates. (Wright, 1989, pp. 233 and 238)

Prima facie, this seems like an accurate description of our account: the information codified in the causal states corresponding to semantic axioms is conceived of as settling in advance, and independently of anything we go on to say or do, the content of the totality of admissible sentences in the language.

But why should this be a problem? What is wrong with the picture of language as a syntactico-semantic mechanism whose output competent speakers are able to track? Wright's suggestion is that it is precisely this sort of picture of the ability constitutive of language mastery which is the ultimate target of Wittgenstein's remarks in the *Investigations* and elsewhere on the nature of rule-following: that if we try to construe language mastery as an ability to track states of affairs constituted independently and in advance of what we say or do, we shall find ourselves unable to give any coherent account of the epistemology of the tracking accomplishment. (For further discussion, see Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING, §4.) Thus, the question here is: *Does the account of tacit knowledge which uses the mirror constraint actually commit us, as Wright suggests, to conceptions of meaning and linguistic understanding which the rule-following considerations would counsel us against?* Perhaps one way to try to avoid an affirmative answer to this question would be to retain Davies's version of the mirror constraint as it stands, but drop the claim that the causal explanatory states corresponding to semantic axioms have informational content – that they represent information – which somehow settles in advance the content of the intentional states constitutive of sentential understanding. It is difficult to assess this suggestion in the absence of an account of what the relationship between the causal states and the axioms is, and of when causal states which are not genuinely intentional can be claimed to have informational content.[16] John Campbell takes Evans to be suggesting that the causal states underlying language mastery have no such content:

> [Evans suggests that] the discernment of structure by a description of understanding is in effect a discernment of non-psychic, purely neural structure … [and that] there is no *psychological* machinery which typically explains a speaker's perception of the meaning of the heard sentence. (Campbell, 1982, p. 24)

Davies, on the other hand, is explicit in his desire to take the opposing view:

> We ought to explore the differences between propositional attitudes *and other information-containing cognitive states*. (Davies, 1986, p. 140; see also his 1989)

Deciding who is right would require a full account of the sort of content possessed by "subdoxastic states," together with an account of the conditions under which such content should be ascribed. This question should, perhaps, be the starting point for any future discussion of the notion of tacit knowledge. Rather than address that here, though, I'll finish by pointing the reader in the direction of a series of papers in which I argue that Wright's own account of the upshot of the rule-following considerations is consistent with the idea that the underlying causal states mentioned in the mirror constraint can be viewed as possessing informational content in a way that would subserve a cognitive-psychological explanation of our capacity to understand novel utterances.[17]

Notes

1 We should distinguish between two senses of the phrase "theory of meaning." This could signify, on the one hand, a theory relating to a single language which attempts to state the meaning of every sentence in that language; or, on the other, a theory relating to language in general, which "attempts to analyse, elucidate, or determine the empirical content of the concept of meaning in general" (Sainsbury, 1979, p. 127). In this chapter we will be concerned exclusively with theories of meaning in the former sense. I shall assume that a natural language is one which is learned by training and projection from that training.

2 In what follows I assume that the meaning-specifications have the form of truth-condition specifications, in the manner of essays 1–5 of Davidson (1984). (See also Chapter 2, MEANING AND TRUTH-CONDITIONS: FROM FREGE'S GRAND DESIGN TO DAVIDSON'S.) This assumption has been widely disputed: see Dummett (1975; 1976). But I do not enter into these issues in this chapter: for our present purposes, nothing of importance hinges on the outcome of that particular debate.

3 Stephen Stich (1978) suggests a necessary condition on a cognitive state's counting as a genuine belief which is very similar in spirit to the constraint which we just extracted from the Evans–Wright discussion. Stich uses the notions of *inferential integration* and *insulation*. Whereas genuine beliefs form inferentially integrated subsystems of an agent's cognitive states (in the sense that there are *many* inferential routes, both deductive and inductive, from a given belief to any other belief), *subdoxastic* states, in contrast, are inferentially insulated from the vast majority of the subjects' genuine beliefs, in the sense that a subdoxastic state will be linked inferentially to only a very limited range of the agent's beliefs.

4 Might there be other reasons for finding the notion of tacit knowledge of meaning-delivering theorems problematic? How could the theorems encapsulate a rule governing the use of sentences, followed even by competent speakers who do not register the theorem in consciousness? As Wright puts it (1986, p. 218), "How can a principle function as a rule if those who engage in the practice which it is supposed to regulate have no consciousness of it?" Wright convincingly rejects this line of objection to tacit knowledge of theorems. In addition, we might add that if Wittgenstein's rule-following considerations have taught us anything, it is that the following question is no easier to answer: How can a principle function as a rule if those who engage in the practice which it is supposed to regulate *are* in fact conscious of it?

5 Note that it would be a mistake to think that a similar argument could reinstate tacit knowledge of a meaning-theoretic axiom as a genuine propositional attitude, since tacit knowledge of an axiom A can equally interact with a multiplicity of other states, namely, those corresponding to the sentences in which the expression governed by A appears. There is no real analogy with the example concerning genuine beliefs, since the states corresponding to the axioms will be implicated only in the causal explanation of the agent's possession of the states corresponding to the theorems. No such implication need hold in the belief example: for example, the belief that P might not play any part in the causal generation of the belief that $P \rightarrow Q$. ("Interact," as it appears in Constraint 2, really concerns *rationalistic* explanation: to say that state A interacts with state B to lead to state C is to say that state A and state B together rationalistically explain the presence of the state C. The crucial point about the axiom-theorem case will then be that the citation of the state corresponding to the axiom will be redundant, so far as rationalistic explanation is concerned (as I go on to argue in the text).)

6 Hess took two photographs of the same girl, enlarged the pupils of her eyes in only one of them, and then showed the two pictures to a range of male subjects who were unaware of the change. Hess found that the males consistently described the girl as looking more attractive in the altered picture, although they were unable to say in what the difference consisted. The idea is that there must have been causal states of the males containing information about relative pupil size which played a part in the causal production of the explicit beliefs about relative attractiveness, although those causal states are not to be counted as genuine beliefs in themselves. For a fuller discussion of the Hess experiment, see Stich (1978, pp. 503, 505–506, and 511).

7 In correspondence, Lars Dänzer has suggested that although tacit knowledge of a semantic axiom never figures non-redundantly in a rationalistic explanation of linguistic action, nevertheless, since beliefs about word meaning *can* figure non-redundantly in rationalistic explanations of beliefs about sentence meaning, there are still grounds for viewing knowledge of a semantic axiom as a genuine intentional state. This is an interesting suggestion, but I'm unconvinced for the following reason. As we'll see more clearly below, tacit knowledge of an axiom such as

(1) "a" denotes Harry

is to be viewed as underlying competent use of sentences in which the name "a" is *used* (such as e.g., the sentence "a is F"). However, a belief about the meaning of "a," on Dänzer's suggestion, is implicated in the rationalistic explanation of a speaker's acceptance of a sentence in which the name "a" is *mentioned* rather than used – for example, his acceptance of the sentence "'a is F' means that Harry is bald." So the fact that a belief about word meaning can figure in this latter sort of explanation does not license the construal of tacit knowledge of a meaning-theoretic axiom as a genuine propositional attitude. The distinction on which this point turns is perhaps masked by the fact that the formulations of the mirror constraint given below are couched in terms of a speaker's beliefs *about* the meanings of sentences. In these formulations, though, "a speaker's belief about the meaning of a sentence S" really refers to the cognitive-psychological state implicated in his understanding *of* S rather than to a belief that potentially rationalizes his acceptance of sentences in which S is mentioned. (For reasons similar to these, I suspect that Bernhard Weiss's (2004) argument that – *contra* Evans and Wright – knowledge of word meaning can count as a genuine propositional attitude fails to establish that tacit knowledge of a semantic axiom can also be viewed as a genuine propositional attitude.)

8 Note that the analogue of the listiform theory for a language with an infinite number of sentences is provided by an infinitary axiom schema: A is T iff P, "where 'P' may be replaced by any declarative sentence of the object language and "A" by the quotational name of that sentence" (Wright, 1986, p. 211).

9 There's an obvious connection here with Gareth Evans's "Generality Constraint": see Evans (1982, pp. 100–105).

10 We ought to note, in fairness to Evans, that this seems to be precisely what he was after in the first place – witness his claim that dispositions have to be given a full-blooded characterization.

11 Note that this holism does not imply that we shall not be able to pair explanatory states with individual axioms.

12 Darragh Byrne (2004, p. 73) attempts to criticize the argument of mine outlined in this and the previous paragraph. He suggests that Wright's objection is that Evans has not done enough to justify the idea that the states corresponding to the axioms of T2 have genuine representational contents. He argues that it is irrelevant that the recursive syntax that satisfies the mirror constraint is "semantic in nature": "[T]he 'supplement' which Wright suggests might explain the structure underpinning the speaker's competence is not this mirror-constraint-satisfying syntactic theory *itself* – the 'supplement' is *based* on that syntactic theory" (2004, p. 73, Byrne's emphases). It's not obvious to me that Byrne's characterization of Wright's objection is correct, but even if we assume that it is, his remarks are unconvincing. Wright clearly takes the syntactic theory itself to provide the necessary detail about the relevant causal structure. He writes: "Admittedly, such a rider [what Byrne calls the 'supplement' – AM] would not be a detailed, or axiomatic, description of the interrelations which the Mirror Constraint would have a theory of meaning reflect. *But there is every reason to think that the recursive syntax which the theorist adjoins to his infinitary semantic theory would supply the materials for the more specific descriptive task*" (Wright, 1986, pp. 213–214, my italics in the second sentence). Wright clearly thinks that the detail on the causal structure is provided by the *syntax* rather than the rider ("supplement"). And even if Byrne were correct in thinking that it was the rider that provided the relevant detail, his admission that it is *based* on an explicitly syntactical (but implicitly semantical) theory would leave my argument against Wright intact.

13 Given my remarks at the start of §2, this shows that the construction of semantic theories in accordance with the mirror constraint can also help to answer the question about learnability.
14 Louise Antony independently runs a similar line of argument in her (1997).
15 So although I do not want to go so far as to claim that "the right account has not greatly impinged upon the consciousness of workers in the field," I would suggest that the most efficient way of implementing that account seems to have eluded many of its practitioners.
16 Note, though, that if we take this line we appear to lose the possibility of explaining, in cognitive-psychological terms, our capacity to understand novel utterances.
17 The relevant papers are Miller (2007; 2012; 2013). A fuller discussion of tacit knowledge would also have to include a discussion of "the doctrine of essential linguistic structure," as discussed in Fricker (1981) and Sainsbury (1979). I discuss this issue – doubtless not at the length it deserves – in Miller (2012, §4). I would like to thank Michael Clark, Lars Dänzer, Martin Davies, John Divers, Jim Edwards, Bob Hale, Bob Kirk, Greg McCulloch, Joe Mendola, Stephen Read, Ali Saboohi, Mark Sainsbury, Laura Schroeter, Roger Squires, Jim Stuart, and Crispin Wright for very helpful comments and discussion.

Radical Interpretation

JANE HEAL

1 A Bird's-Eye View of Some Options

To engage in radical interpretation is to set about investigating the meanings of utterances in some completely unknown language. It has been suggested that reflection on how such interpretation should proceed will throw light on the nature of meaning. The most influential proponent of this idea is Donald Davidson (1984, especially essays 9–12). This chapter will therefore be much concerned with his proposals. But it aims also to locate his views in a broader context and to consider alternative approaches.

The structure of this chapter is as follows. The remainder of this section discusses the location of radical interpretation within the broader field of philosophy, and identifies some of the options and their presuppositions. §2 outlines the ideas of Davidson; and §§3, 4, and 5 consider their contrasts with alternative views, seeking to identify the crucial issues.

Two things need clarification at the start. The first is that the epistemological appearance of the enterprise, if taken too seriously, could be misleading. To think that we should get illumination on the ontology or metaphysics of some concept by asking how judgments using it are established is characteristically an empiricist view. But talk of "what one would need to know in order to establish such-and-such" may also be a mere rhetorical device for the vivid presentation of independently motivated metaphysical proposals. We should regard our reflections on the imagined procedures of radical interpretation in the second way and not the first. This is clearly the approach of Davidson and others; the investigations they speak of are highly idealized, and neither they nor we wish to commit ourselves at the outset to controversial aspects of empiricism (see Davidson, 1990, and Lewis, 1983, pp. 110–111).

A second point needing early clarification is that our quarry is not just the notion of linguistic meaning but also a broader notion of meaning or representational content, in which such content may be attributed to psychological states as well as to linguistic items. We are to think about what fixes the content of a person's thoughts as well as about how we

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

could identify the meaning of what he or she says. Davidson takes it that thought cannot occur without language, and that language is the primary vehicle of thought (1984, essay 11). So for him it follows immediately that investigation of the nature of thought and investigation of the nature of language are one and the same. But even those philosophers who do not accept this are likely to agree that thought and language are closely linked. It seems impossible that, for a language-using creature, there could be two entirely independent sets of facts, one about what he or she thinks and one about the meaning of what he or she says.

What exactly is 'radical interpretation'? And what is presupposed by the idea that it is possible? Its proponents seem to mean by the phrase an inferential process which starts from information, *all* of which is non-semantic, and ends with attribution of rich and varied meanings. Thus Davidson says that radical interpretation must start from "evidence that can be stated without essential use of such linguistic concepts as meaning, interpretation, synonymy and the like" (1984, p. 128). Lewis characterizes the matter thus:

> At the outset we know nothing about [our subject's] beliefs, desires and meanings … Our knowledge … is limited to our knowledge of him as a physical system … Now, how can we get from that knowledge to the knowledge we want [sc. the knowledge of meanings]? (Lewis, 1983, p. 108)

To give this description is not to say that radical interpretation cannot have among its starting points some general principles about meaning, in the form of explicit or implicit instructions on how to process the non-semantic information presented. Clearly without such general principles we should be completely hamstrung. But the starting information is not to contain any attributions of actual particular meanings, even to expressions of one's own language, since on Davidson's fully developed theory our knowledge of the meanings in our own first language is based on radical interpretation.

We can see why this restriction on the nature of the evidence might be imposed by someone who wishes to use reflection on radical interpretation to cast light on the metaphysics of meaning, that is, on the nature of meaning as a phenomenon and on its relation to other kinds of fact. If we imagine ourselves interpreting non-radically – inferring to meanings from a mixed body of knowledge containing facts about meaning as well as non-semantic facts – it may be that we can, on reflection, discover some distinctive patterns of relation between our non-semantic premises and our conclusions. It will, however, be difficult to build much upon this for metaphysical purposes (to use it, for example, to build theories of the relation of the semantic to the physical) until we are clear what has been the distinctive contribution of the additional semantic premises. But it is precisely the nature of the semantic which we are trying to clarify. And thus we risk going round in a circle. The claim here is not that any philosophical enterprise of this shape is bound to be hopeless; the claim is only that it is apparent that metaphysical conclusions could much more easily be drawn if the inferences were 'radical' in the sense outlined.

We can now see clearly at least one presupposition of the idea that radical interpretation is possible; it is that rich meaning notions are not an essential part of the basic observational vocabulary with which we approach the world. We may speak colloquially of hearing a person say that something is the case, or seeing that a person is thinking such-and-such. But, says the believer in radical interpretation, this is a mere useful idiom, not to be taken seriously. What is really observationally apparent must be something less committal, for example that certain sounds or movements were produced in certain patterns, having such-and-such causes, and the like. Facts about meaning are somehow based on or inferred from such facts.

Let us for the moment accept that there could be such a radically non-semantic starting point as the one imagined. There are now broadly two possibilities for how the attempted working-out of meanings might go. First we could maintain a form of dualism. On this view, possession of meaning by a physical vehicle is a matter of that vehicle being suitably related to some unobservable entity, or itself having some unobservable property. Perhaps, for example, it is the effect of some intrinsically representational state of a Cartesian mind. (This is the theory of substance dualism.) Or perhaps it has in itself another hidden or mental aspect. (This would be the theory of a 'double-aspect' property dualism.) The investigation of meanings on this hypothesis is very similar to the investigation of micro-organisms or invisible dwarf companions to visible stars. Only it is not quite like this, because dualistically conceived meanings are also thought of as *in principle* unobservable, even with microscopes or spaceships. They are thought of as causing public manifestations, but being essentially linked, in a distinctive and epistemologically privileged way, to their subject. There are many familiar lines of argument against dualist positions, for example the fact that they produce 'other minds' problems and that they make it difficult to give an intelligible account of mind–body interactions.

Those philosophers who write on radical interpretation and whose work we shall consider take it for granted, however, that dualism is not a serious option. This means that, for them, the other possibility is the one which must be accepted. This possibility is that all the facts that are relevant to meaning are there in the non-semantic (that is, the physical or material) assemblage. Meaning is not, as in dualism, something independent of this assemblage but is, on the contrary, something fixed and constituted (in so far as it is fixed and constituted) by the non-semantic. So any materialist theory of mind which is non-eliminativist and which addresses itself seriously to the question of intentional content is a theory of radical interpretation.

It is not the case that the believer in the possibility of radical interpretation who also rejects dualism is committed to any simple-minded form of reductionism. He or she is not committed, for example, to the idea that semantic statements can be translated or unpacked one by one into packages of non-semantic ones. As we shall see, Davidson's proposal is very different from anything of this kind. But it is the case that the believer in radical interpretation is committed to the idea that the semantic arises from, or is constituted by, some kind of appropriate complexity in the non-semantic. For want of a better word, I shall say that he or she is committed to the reducibility of the semantic to the non-semantic. But it is to be remembered that what is involved is reducibility in some extremely broad sense.

The difficulties of dualism have given a bad name to the whole idea of non-reductive accounts of meaning (in the very broad sense of 'reduction' just gestured at). The bulk of philosophical writing on meaning (in the analytic tradition) has thus been concerned to pursue the radical interpretation strategy. But are dualism (in which a hidden and separate meaning is inferred *behind* the non-semantic surface) and a reductive materialist view (in which it is discerned *in* the patterns of the non-semantic) the only options? What if we abandon the assumption common to the materialist accounts and dualism, namely that meaning is not observable, while retaining dualism's commitment to non-reductionism? This gives us a view on which meaning is a public and observable property of certain sounds, marks, or movements, but a non-physical one. So the concept of meaning is a descriptive and factual one, and also, very importantly, a basic observational one. But it is not part of that predominantly quantitative and value-free conceptual scheme we have built up for describing, predicting, and explaining the behavior of inanimate objects; rather, it

belongs to a different but equally fundamental area of thinking, namely the one we use in our relations with other persons. This line of thought is favored by those with Wittgensteinian sympathies. If we accept this view it is likely that the idea of the imagined starting point for radical interpretation, a starting point in which a person knows plenty of non-semantic facts but no semantic facts at all, will come to seem incoherent. The starting point for any thinking is one in which we are observationally aware of the world as containing both semantic and non-semantic facts.

This option will seem to many extremely wild, because it clashes with certain widespread but often unarticulated assumptions about fundamental matters like fact, truth, and perception; so to make it seem even coherent, let alone plausible, we would need to reappraise our views on these topics. But before considering whether we need to embark on that unsettling enterprise, we should surely see whether we cannot find something more immediately congenial in the radical-interpretation camp.

We have then at least the following questions to ask. Is radical interpretation possible? If it is, what are the strengths and weaknesses of the particular variants proposed? If it is not, why does it fail and what should we put in its place?

On this last question, let us remember that in addition to dualism and the Wittgensteinian option sketched we have at our disposal also such views as eliminativism and instrumentalism. The first of these says that psychological concepts, including those of content and meaning, are so confused and/or scientifically ill-grounded that nothing answers to them, and hence no theory of their (true) applicability is required (Churchland, 1988; Stich, 1983). The second says that talk of meaning and content is a useful tool but not to be factually interpreted (Dennett, 1979; 1987).

For various reasons, our entry point into these issues will be consideration of the views of Davidson. The topic we are considering got its name from him, and some important themes emerged in his writings. Focusing on them allows us to identify interesting points of contrast between different theories of radical interpretation. But it is also arguably the case that his view, if correct, contains the seeds of its own destruction, in that it leads to unacceptable claims about the indeterminacy of meaning, and might thus lead us to question the validity of the whole radical-interpretation project.

It is, however, difficult to see at first reading what is of central importance in Davidson's work, because the form of his proposal is substantially but unhelpfully influenced by its history. We turn therefore in §2 to a brief sketch of its development and summary of its mature form.

2 From "Truth and Meaning" to "Radical Interpretation"

A distinction it is useful to have clear is that between providing an analysis of a concept, an account which clarifies its links with other concepts and hence its metaphysics, and providing what I shall call a 'calculus' for that concept, a set of rules for working out if it is applicable to an item on the basis of information about the composition of that item. (See Heal, 1978, for more on this distinction.) For example, consider the claim that sodium nitrite is poisonous to octopuses. A person can show that she knows very well what this means – by unpacking the claim in terms of what will happen to octopuses who ingest sodium nitrite. But this person may be in no position to say whether the claim is true or not, because she has no sodium nitrite or no octopuses, or cannot get the latter to eat the former. Another

person might, by contrast, be in a position to rule on the truth of the claim, because he is in possession of a set of instructions for calculating to what creatures, if any, a chemical compound is poisonous, from a canonical specification of the elements in the compound and their mode of bonding. This person might, however, not fully understand the claim, because for him 'poisonous' is little more than a dummy predicate and he has no grip on its relations to eating, illness, and so forth.

For many concepts, as for 'poisonous,' analysis is independent of calculus. It is a contingent matter whether or not there is a calculus of poisonousness. And even if there is a calculus one can understand 'poisonous' very well without suspecting this, let alone knowing what it is. But for meaning things are different. And this is the starting point for Davidson's discussion in "Truth and meaning" (Davidson, 1984, essay 2; see also Chapter 2, MEANING AND TRUTH-CONDITIONS: FROM FREGE'S GRAND DESIGN TO DAVIDSON'S). He is concerned to emphasize that an item cannot have sentential-type meaning, that is, be the vehicle for a complete linguistic move, unless it is complex. Any such sentence must be built up from words which, together with their arrangement, determine the meaning of the whole.

His arguments rest heavily upon the fact that natural languages allow for the construction of indefinitely many new sentences. In them a finite number of words are built together in increasingly complicated arrangements by application (repeated if need be) of a finite stock of constructions. Unless we see sentences as built in this way it is entirely mysterious how finite creatures like ourselves could have the language-speaking and -understanding capacities which we do.

These considerations are weighty; and we can cite others which point in the same direction. Even if a language had only a finite number of sentences there would, I suggest, be reasons for thinking that sentence-style meaning requires the existence of words or word-like complexity in the sentences. It is central to the notion of meaning (for contingent *a posteriori* sentences at least) that meaning is one thing and truth-value another. Imagine now some item which has a meaning of this kind and is also false – for example, an item which means 'snow is green.' Try to suppose also that this item entirely lacks semantic complexity in its properties or relations; its having the meaning it does is a one-off matter, and not bound up with any systematic connection with any other meaning-bearing items. We seem here to have something completely unintelligible. The difficulty is not merely epistemological – how could we tell that the item had this meaning? – but also constitutive: what could there be about it which fixes that it is about snow or about greenness? One-word indexical sentences – like 'Fire!' – do not provide a counter-example to this claim. What is required for a linguistic move is a token, and each token of this sentence does exhibit two separable features, namely its type and its spatio-temporal location, which contribute independently to fixing the claim made by the whole.

So Davidson's starting point in "Truth and meaning" is the fact that 'S means that p,' when unpacked, turns out to commit us to the idea that S is a complex item which will have a number of different features, each with its own semantic role, which jointly determine the meaning of S. Let us go along with him in assuming that the features are the presence of identifiable words. This is not obligatory. The features could be things such as color, size, or shape, or they could be relational properties. But the word-hypothesis simplifies exposition without distorting the issues we are concerned with here.

But if S contains words then it must be (potentially at least) part of a language. There must be (the possibility of) other words which could replace some of the words in S, and so the possibility of other sentences which could be built from different combinations of those

words. So 'S means that p' turns out to have the following implication: S belongs to a language, that is, a system of meaningful items, for which a meaning calculus can be given which supplies 'S means that p' as an output theorem. Davidson, in "Truth and meaning" conceives his task to be that of unpacking further what any such meaning calculus would have to be like.

Suppose that S is 'a is F,' that we know that it means that a is F, and that we are convinced that 'a' and 'is F' are the semantically relevant subparts. An adequate meaning calculus will assign properties to 'a,' to 'is F,' and to concatenation: these property assignments will be (some of) the axioms of the meaning calculus, and they must entail as a theorem:

'a is F' means that a is F.

What might they be like? Well, says Davidson, we already know of one sort of axiom set which will do exactly this job, namely that employed in a Tarski-style theory of truth. (See Tarski, 1956. For useful expositions see Haack, 1978, and Evnine, 1991.) All this might merely lead to the thought that a Tarskian calculus of truth-conditions and a Davidsonian calculus of meaning will employ the same shape of machinery. It does not yet entitle us to suppose that the notion of meaning can be unpacked into or analyzed in terms of the notion of truth. But this is the bold step which Davidson proposes. He suggests that we abandon Tarski's requirement that the theorems must have on their right-hand sides something with the same meaning as the sentence mentioned on the left, and that we instead demand only that theorems be true biconditionals about truth-conditions. His conjecture is that this, together with the remaining constraint of using finite semantic structure to generate a theorem about every sentence, must narrow down the number of acceptable calculi to such an extent that anything which satisfies the constraints will, in fact, serve as a calculus of meaning.

The proposal, in summary, is this:

'S means that p' unpacks into
'S is part of a language and a correct truth-conditions calculus for this language can be set up which delivers "S is true iff p" as a theorem.'

(Let us enter a caveat here. Davidson denies (1976, p. 35) that this was his proposal, and he implies that he all along intended further constraints. But however this may be, the line of interpretation I have sketched is the most natural reading of "Truth and meaning," and is what most of its readers took Davidson to be saying.)

The proposal is one about the conceptual connection between the notion of meaning on the one hand and the notions of word, language, structure, calculus, and truth on the other. It claims to offer insight into meaning, but not by invoking anything to do with radical interpretation. Why, then, have we spent so much time on it? Because Davidson's later view is, in part, an attempt to rescue the earlier theory; and the later view retains, unnecessarily to my mind, certain features of the earlier one. These are features which many have found particularly implausible, and they have hindered appreciation of other, more important new elements introduced in the later theory. So unless we know a little of the history we shall not understand properly what is going on.

One damning objection to the early proposal which soon became apparent is this (Foster, 1976; see also Chapter 2,

TO DAVIDSON'S). An acceptable truth-conditions calculus for a language can generate the true theorem that S is true iff p, when it is quite clear that S does *not* mean that p. For example, if the properties P and Q by chance characterize all and only the same things, then a calculus of truth-conditions which assigns Q to a predicate 'F' will do just as well as one which assigns P. Yet looking at the speakers of the language, it may be far more plausible that they are speaking about Q than about P; P might be something these speakers could not be aware of, such as a microstructural property, or it might be some gerrymandered compound property like 'having Q while $2 + 2 = 4$,' which is, of course, coextensive with 'having Q.'

Davidson's moves in "Radical interpretation" provide a response to this. He there offers a proposal about meaning which retains a central element of the earlier work, but locates it in an importantly different setting. The retained element is the idea that to say 'S means that p' is to say that S belongs to a language for which an empirically acceptable calculus of truth-conditions delivers 'S is true iff p' as a theorem. But the empirical conditions which make a calculus acceptable are spelt out differently. The demand now is not that the calculus supply true biconditionals about truth-conditions; it is that it deliver theorems which lead to the speaker of the language satisfying the *Principle of Charity*. We shall return to this in a later section. But what it says is roughly the following: *if* we use our candidate calculus to interpret our subject – that is, whenever the calculus says something of the form 'S is true iff p' and the subject says S, then we take him to be expressing the belief that p – *then* he comes out as by and large a sensible fellow, with a mainly correct view of the world.

This condition may now enable us to distinguish between the two calculi (the one which linked 'F' with property P and the one which linked it with property Q) that were mentioned earlier. It may be that the overall psychology attributed to the subject using Q reveals him as much more coherent and intelligible than the one using P.

We could, then, just add the Principle of Charity to the earlier empirical condition (that the calculus deliver a correct account of truth-conditions) and leave the overall proposal otherwise untouched. It may seem as if this is what Davidson does. And indeed, his later proposal could be summarized in the form of words we used earlier, with the addition of the extra clause.

But it is important to realize that, at the same time as the Principle of Charity comes on the scene, another change takes place in Davidson's thought, namely a shift of attention from the case of thinking about one's own language to that of thinking about a strange language. The home-language case drops away out of explicit consideration. When mentioned, it is presented as just another case of radical interpretation, but one where familiarity disguises this fact from us. The effect of this is that the way of understanding what it is for something to be a correct calculus of truth-conditions which was earlier called upon is no longer available. When we are thinking about the home language we can presuppose an implicit understanding of sentences. This makes it straightforward to test theorems delivered by a candidate theory. Suppose I am already a speaker of English, and I am asked whether '"Snow is white" is true iff rubies contain carbon' is a true biconditional. I may not know the answer instantly, but at least I know what I have to do to find out. But when we change the case to an unknown language, matters are very different. Suppose the candidate theory delivers '"Skuppit gromper" is true iff rubies contain carbon.' How am I to tell whether this is a true biconditional about truth-conditions?

It is easy not to notice how big the shift is between the position of "Truth and meaning" and that of "Radical interpretation." The fact that a very similar formulation can be offered may suggest that all that has happened is that Charity has been added in as an extra

constraint. But a crucial point is that with the change of focus from the home case to the alien, the earlier account of empirical correctness needs replacement. And with its replacement, the whole shape of the enterprise changes. The earlier project aims for an account of linguistic meaning in terms of truth. It tries to illuminate the intensional semantic notion of meaning by unpacking its links with the extensional notion of truth, together with the notions of structure and calculus. This project works within a circle of semantic concepts and it applies only to linguistic items; views about the nature of persons and psychological states are not brought in at all. The second project is, by contrast, in many ways more ambitious. It offers to give an account of *both* meaning *and* truth, which are now put back together as an inextricable pair, neither of which is more fundamental than the other. And the account it offers is extended to apply to psychological states as well as to linguistic items. The story it offers, to put matters extremely briefly, sees meaning, language, truth, and thought all as needing to be explained in terms of patterns discernible in uninterpreted behavior.

Let me now spell out in more detail the fully fledged, later proposal. First some preliminaries. It is supposed that we can identify prior to interpretation the class of sentences which the subject holds true, that is, those he or she is willing to assert sincerely. Patterns of recurrent elements can be discerned in those sentences. The patterns are of such a kind that a finite calculus of truth-conditions can be set up which covers all sentences of the language. This is to say that we can hit on a finite number of axioms which assign semantic properties to the recurrent elements in such a way that we can derive for every sentence some theorem assigning it truth-conditions. The pattern of actions and utterances is also such that use of this calculus as a tool for attributing attitudes makes the subject come out as satisfying the Principle of Charity. Let us call such a calculus 'an empirically correct theory of truth' for the language in question. Now we can state the proposal thus:

> 'S means that p' unpacks as
> 'S is true iff p' is a theorem of an empirically correct theory of truth for the language containing S.

And

> 'A thinks that p' unpacks as
> There is some S which A holds true and S means that p.

Davidson draws the following conclusions from this account: that meaning is a normative notion, implicated with what he elsewhere calls "the constitutive ideal of rationality" (1980, p. 223) and that meaning is to some extent indeterminate, in that alternative calculi of truth-conditions could well be set up which satisfied all the constraints equally well. We shall consider the first of these claims in §4 and the second in §5. But we turn first to another matter.

3 The Basis for Radical Interpretation

How does this approach compare with other theories which share the basic assumption of the radical interpretation program, namely that meaning must somehow be based in or derived from the non-meaningful?

Most other approaches of such character have in common a broadly functionalist and naturalistic orientation. They suppose that the nature of psychological notions is to be elucidated by pointing to their causal role *vis-à-vis* behavior. They thus tend to share a sympathy with the idea of unpacking semantic relations in terms of causal relations. For a person to be thinking that a is F is for him or her to be in a state with suitable causal relations to a and to F-ness. Where they differ is in the spelling-out of what 'suitable' means. Some call on the idea of a language of thought, in which individual words have semantics fixed by their individual causal histories (Field, 1978; Fodor, 1975; 1987). Some give an important role to the etiology of internal structures in natural selection (Millikan, 1984; Papineau, 1987). Others call upon the notion of information (Dretske, 1981). Here I cannot hope to do justice to the variety and ingenuity of theories proposed (see Chapter 8, A GUIDE TO NATURALIZING SEMANTICS). Instead I shall ask where they, or large subgroups of them, seem likely to come into conflict with the Davidsonian view sketched at the end of §2, in the hope that this will bring into focus at least some of the interesting issues in the area.

One immediate point of contrast stands out, namely that most theories other than Davidson's would take as their base not a set of facts about 'holding true,' but the totality of physical facts. In defense of his starting point Davidson writes, "[Holding true] is an attitude an interpreter may plausibly be taken to be able to identify before he can interpret, since he may know that a person intends to express a truth in uttering a sentence without having any idea *what* truth" (1984, p. 135). The general claim here is, however, implausible, and the reason given for it (that it is *sometimes* possible to know that a person intends to express a truth without knowing which) does little to support it. A theory of radical interpretation should be applicable to giant octopuses or super beings emerging from their spaceships as well as to newly encountered human beings. But consideration of such non-human cases makes clear that identification of something as a holding true requires ability to distinguish voluntary from involuntary and linguistic from non-linguistic behavior. There is every reason to suppose that making these distinctions will involve simultaneously making rich hypotheses about the contents of beliefs and purposes. A similar point can be made in connection with speech acts other than sincere assertion, such as commands, stories, and irony (1984, p. 135). Davidson does mention these, but he underplays the fact that distinguishing them from sincere assertions (which we shall have to do if we are to identify the holdings true before interpretation) also requires attributions of rich and complex intentions.

So, in brief, Davidson's proposed radical interpretation starts in a place which is either not available or is not radical. Moreover, even if that place were available, his methodology would have us ignore evidence about the placement of speech in the context of non-linguistic action. But such placement might surely give us useful clues to meaning. And indeed Davidson himself, at another point (1984, p. 162), remarks that a theory of interpretation cannot stand alone, but will need to be integrated within a more comprehensive theory of thought and action.

Why, then, should Davidson have chosen as basic this unsatisfactory 'holding true' notion? One explanation is the powerful influence on him of the Quinean radical translation model. (See Chapter 26, INDETERMINACY OF TRANSLATION.) But another is the desire to carry forward as much as possible of the shape of the "Truth and meaning" theory. There we assumed that we started with an identified body of sentences for which we know truth-conditions, namely the sentences of our own language. The test of a proposed calculus was then simply whether it delivered correct statements about truth-conditions for these

sentences. The nearest we can get to this position, if we shift to a radical situation, is to imagine, first, that linguistic behavior at the start neatly differentiates itself from the rest, and second, that we can establish by observation the conditions under which each sentence is held true. On those assumptions (and *very* importantly, given *also* that holding-true conditions for the most part coincide with actual truth-conditions: see the next section) then we can proceed very much as we did on the "Truth and meaning" story. But the moral of the discussion of non-human cases is that this is not a persuasive line. A desire to duplicate the earlier structure as far as possible has led to the implausible idea that sentences held true can be isolated from the rest of behavior prior to interpretation. The totality of physical facts would be a much less tendentious place to start.

Davidson's proposal, then, needs modification in at least two ways. The first is the change in the imagined starting point, and the second is the need to take account of the relation of linguistic behavior to its context in action. The upshot of such changes would be a theory rather like that proposed by Lewis (1983). The idea is, briefly, this: to say 'A thinks that p' or 'A's utterance S means that p' is correct provided that these claims would be delivered by an acceptable overall theory of A's behavior; a theory is acceptable if it attributes beliefs, desires, intentions, and meanings to A (and thus licenses redescription of some mere movements, noise-makings, and so on as actions and utterances) in such a way that (1) A has a language with a finitely specifiable and reasonably simple semantic structure; (2) A has, by and large, a true, rational, and epistemologically defensible view of the world (that is, he satisfies the Principle of Charity); and (3) A comes out as doing and refraining in action (including linguistic action) in the way expected of a rational person with the intentional states attributed.

What is there in this which might still provoke objections? The Davidsonian idea that there is a link between meaning on the one hand and system or structure on the other is still very much in play. The proposal assumes that nothing can be seen as a meaning-bearer (whether an action expressive of intention or an utterance expressive of belief) unless it is part of a repertoire of other possible items with which it is contrasted. Methodologically, we are exhorted to use these contrasts and the circumstances of their occurrence as key diagnostic elements for interpretation. And this, the insight stressed at the start of §2, is not, it seems to me, something with which any theory of meaning need quarrel. (However, the most unlikely quarrels are pursued. See Fodor and Lepore, 1992, especially ch. 3.)

A potentially more controversial feature of the proposal is that it has a behaviorist flavor. What licenses and makes true attributions of meaning is a certain sort of patternedness in observable behavior. It is not a trivial matter that behavior should be amenable to redescription in terms of a rational psychology, any more than it is a trivial matter that a certain set of intricately shaped and colored flat wooden shapes should fit together in a jigsaw to present a recognizable picture. In both cases it is a matter of individual items locking together, literally or metaphorically, in the right kind of way. And we can imagine sets of items which do not fit. But some might wonder whether such a merely surface feature of behavior was a sufficient condition of thought and meaning, and whether we should not demand also that there be inner causal mechanisms answering in structure to the beliefs and desires attributed.

We shall return to this issue. But first we shall consider another possible source of disquiet, namely the role given in the proposal to the Principle of Charity. Is the Principle, as some have thought, hopelessly parochial? Is it over-optimistic about the likely success of thought? And what does it have to do with some supposed normative aspect to meaning?

4 Interpretation, Charity, Holism, and Norms

To start with, let us look at the early history of the Principle of Charity, when it was, rightly, found unattractive. We should, said Davidson, insist *a priori* that an interpreter find a calculus "which yields, so far as possible, a mapping of sentences held true (or false) by the aliens on to sentences held true or false by the linguist" (1984, p. 27). What this amounts to is that we must make the assumption that pretty well everything we say, and also pretty well everything the aliens say, is true. (Davidson explicitly draws out these anti-skeptical implications of his position in 1984, essay 14. See also Evnine, 1991, ch. 8.)

Why does Davidson make this recommendation? Following our earlier line, a conjecture is that it is because this is the simplest way of converting the "Truth and meaning" proposal for use on an unknown language. For my home language I am able to test whether a truth-conditions calculus is empirically acceptable by seeing whether the theorems it delivers are true. I can do this on a one-by-one basis, using my taken-for-granted knowledge of my own language together with ability to find out about the world. But when we deal with an unknown language, this method is inapplicable. Since I do not understand the sentences, I do not know what to enquire into to test a claim about their truth-conditions. (We have already touched on this point earlier, in §2.) But if I could just *equate* the aliens' being willing or unwilling to assert a sentence with that sentence's being true or false then this lack of understanding need not handicap me. I do not need to investigate the truth of their sentence directly in order to test a candidate calculus; I need only to find out whether the aliens *hold* the sentence true and then, simply assuming that it is true, I find out whether the conditions which the calculus assigns to it do obtain. If they obtain, then the theory is confirmed. Doubtless I must make some allowance for the possibility of the aliens making occasional errors. But if I can insist *a priori* that such mistakes must be extremely rare, then the above simple testing strategy is available.

The early formulation of the Principle of Charity, however, produced objections. It seems to involve the claims, first, that we already have pretty well all the thoughts there are to have (because any set of thoughts can be mapped on to ours), and second, that our beliefs are pretty well 100% correct. These claims appear to underrate the possibilities both for ignorance and for error.

The first claim is in fact not essential to the proposed method. Davidson need not deny our possible ignorance of many aspects of the universe, and he ought to allow that the process of interpretation could be one of substantial learning about the world, that is, it need not merely be one of pairing things we already know with things the alien subject knows. What is more crucial is the claim of substantial correctness in all systems of thought, including our own current one, since it is this claim which underpins the rough equation of 'the subject holds S true' with 'S is true' in our investigative methodology. This second claim is objectionable, however, in that it is either highly implausible or hopelessly unclear. If it is taken to mean that the *actual* sincere utterances of any group of persons must be largely true, it is implausible. It rules out the idea that an extensive part of the lives of a group of persons should be concerned with the pursuit of some chimerical and theoretically ill-based enterprise. How can we rule out *a priori* the idea that our societies might have evolved in such a way as to doom most of us to think and speak, a large proportion of the time, about alchemy, astrology, or historical materialism? But if we shift instead to consider merely *possible* utterances and our willingness to assent to them, the content of the claim becomes extremely unclear, as Davidson himself later hints (1984, p. 136).

Possible utterances form an indefinitely large set, and so quantitative claims about proportions of truth and falsity in the set have no obvious meaning.

So it looks as if "Truth and meaning" is again exerting an unfortunate influence, and has led Davidson to an indefensible position. Before considering whether anything can be rescued, we need to distinguish two different roles for a principle like the Principle of Charity. (Useful moves in this direction are made in Malpas, 1988.) One role is played at the start of the attempt to interpret. Davidson claims that interpretation of words and attribution of beliefs combine to explain utterance. But, he says, we cannot access the beliefs expressed in an utterance prior to and independent of grasp of the meaning of the utterance. Nor can we do the reverse. We need, therefore, to make some initial assumption, in order to begin to test and elaborate any theory. Davidson's way out of the impasse is that we should start by taking it that the beliefs of the other are the same as ours.

There is much that is attractive here. Even those who think that non-linguistic behavior can provide very strong or conclusive evidence for certain beliefs (and hence would reject the detailed Davidsonian proposal, with its stress on language) may recognize an analogous problem in the way in which belief and desire cooperate to produce action. Thus it is a plausible thought that any interpretive enterprise will have to start off by trying out some assumptions in order to break into a circle. And it is also plausible that a good place to start is with the idea that the others are like us.

One alternative to the Principle of Charity, following this line of thought, is sometimes called the Principle of Humanity. It does not recommend us to attribute to our subject as a starting hypothesis the very thoughts we ourselves actually have. But it suggests a close variant, namely the thoughts we would have had, if we had been through someone else's life experiences (Grandy, 1973; Lewis, 1983). This, indeed, looks a useful suggestion and better than straight Charity. If all that was at issue was methodological advice on how to start out interpreting, perhaps we should stop here.

But it is not all that is at issue. However useful as a tip on how to *start*, neither Humanity nor Charity tells us where we shall *end up*. What if our initial assignment of thoughts based on the principle does not work out? What if further investigation makes it seem likely that our subject has different sensory apparatus and/or different emotions and interests from us, and so has significantly different views from any we do or would have had? In these circumstances we must modify our starting hypothesis. And we need at this point to know what constraints there are upon the shape of theory we may move on to, and how to evaluate rival emendations.

Let us now look at one of Davidson's own later remarks. He stresses (as do proponents of the Principle of Humanity) that any interpretation must allow for intelligible error. He writes:

> It is impossible to simplify the considerations that are relevant [i.e., to assessing a proposed theory] for everything we know or believe about the way evidence supports belief can be put to work in deciding where the theory can best allow error and what errors are least disruptive of understanding. The methodology of interpretation is, in this respect, nothing but epistemology seen in the mirror of meaning. (Davidson, 1984, p. 169)

The important theme here is that any set of thoughts we attribute to a subject must come with (or with the possibility of) some intelligible epistemology. This principle, if correct, applies not only to what we guess when we start out interpreting, but to hypotheses at all

stages. Something else stressed by Davidson, and which is part of the same line of thought, is the prominent role given to indexical utterances in providing some anchorage for interpretive theories. We must be able to see some utterances as expressing perceptual judgments about the world around the subject.

What does this insistence on the need for plausible epistemology stand opposed to? Rejection of dualism about meaning is one of the deep-lying assumptions of the enterprise. Classical dualism moves from belief in the *non-reducibility* of facts about psychology (including facts about content and meaning) to claims of their *independence* from the physical. Such independence would allow us to evade the proposed epistemological constraints. We do not, on a dualist view, have to tell a story about how the subject could, so to speak, have got in touch with what we say he is thinking about. We are allowed to suppose that it just is a fact that he is thinking about it. So on a dualist view, content may float free of public facts about a creature's constitution and placement in the world. This is what leads to its constant implicit threat of skepticism, both about other minds and about the external world.

Let us, however, not identify rejection of dualism with acceptance of empiricism. It is one thing to be very unhappy to attribute to a person a thought about some state of affairs which we believe he or she has had no opportunity to perceive, hear of, or theoretically conjecture. It is another to suppose that some sensory reduction can be given for all thoughts. (See Davidson, 1990, for a discussion of the difference.)

Can we say anything else general about sets of thoughts? Yes, says Davidson. We should recognize the so-called holism of meaning. This is the claim that an intentional state with content cannot exist in isolation, but requires the presence in the subject of many other intentional states with suitable contents. For example, anyone who wonders whether the bank is open must believe a fair number of general things, such as that other people exist, that goods are produced and exchanged, and that money exists; and he or she must also have some suitable beliefs about such things as the nature and location of the bank in question.

This view, the holism of meaning, has some resemblance to the claim, argued earlier in §2, of the necessity for any meaning-bearer to be itself complex and to be placed in a system. But they are not the same view. The mere claims of complexity and systematicity carry no immediate implications about the kind of content which is to be carried by the other elements in the system, while the view currently under consideration emphasizes the need for particular kinds of conceptual content to be present. The relation between the two theses deserves more discussion than it can be given here (The word 'holism' is sometimes used also in connection with the view about the joint operation of belief and meaning in giving rise to utterance. But this is a third, and different view. See also Chapter 15, HOLISM.)

The holism of meaning thesis is offered in support of the Principle of Charity, that is, the idea that there must be 'massive agreement' between our thoughts and any other possible set of thoughts and that we must in consequence be substantially right. It is argued that it implies that disagreement cannot exist except against a background of agreement. To redeploy the earlier example, there cannot be disagreement over whether the bank is open unless there is agreement on at least some things, like the existence of other people, the exchange of goods, the existence of money, and so on. So the idea of detecting pervasive error in another thinker (whether we interpret others or they interpret us) is incoherent.

This is the argument. But it does not, in fact, help us with the trouble we had earlier in applying quantitative notions like 'massive agreement' to indefinitely large sets of beliefs; and hence it does not help in seeing exactly what the content of the claim is. Without

detailed supplementary information (about how much agreement is required to underpin one disagreement, about whether one agreed set of beliefs can underpin more than one disagreement, and so forth) nothing follows about quantities. Such supplementation is unlikely to be forthcoming. We would do well, then, simply to jettison the quantitative style of claim.

What, if anything, then remains of the Principle of Charity? Let us first re-express the original insight of meaning holism. It is that for an item to bear a certain meaning it is required that it exist in a setting of other items bearing related meanings. Thus it is only when a rationally coherent and related group of items exists, a group which can be taken to represent some extended portion of a world, that we can attribute content to any member of it.

Let us pause to emphasize something important at this point. Nothing that has been said requires us to insist that a particular thought requires some given, fixed set of other thoughts. We may do so, if we are sympathetic to the idea of analytic truth. But we could instead demand something weaker, namely only that there be *some* suitable setting to anchor a given content. As an analogy, consider what is required for a dot in a cartoon-style picture to represent a living human eye. One might think (adopting the analytic model) that there had to be a dot for the other eye, a line for the mouth, a circle for the face, or at least a reasonable subset of these. But this is not correct. We can imagine a dot which represents the eye of someone peering through a hole in a screen, where none of the rest of the body is depicted. What is required is that there is enough detail in the rest of the picture to make clear that this is what is happening. Similarly for content, one could speculate. We can attribute a given belief in the absence of its usual accompaniments in us, provided there is some other suitable setting to anchor its meaning. And perhaps there are no ways of cataloguing and systematically studying what 'suitable settings' there could be.

So to return to our current question of whether anything useful can be salvaged from the Principle of Charity. We have so far expressed the holism of meaning in terms which suggest that it is relevant only to small subsets within a set of thoughts. But the implications of the holism are wider. The thoughts which are, so to speak, at the edge of one set will need to be in the middle of another. And thus the idea of the 'suitable setting' will spread to encompass the totality of thoughts. The upshot is that the set must, as a whole, be more or less coherent and so represent what could be one world. We cannot have a fragment here and another contradictory fragment there without losing grip on the idea that it is one mind, one subject's point of view, that we are capturing.

If we now combine this thought with the earlier anti-dualist one, we arrive at the following view. Any set of thoughts we attribute to a subject must be a recognizable representation (however incomplete or distorted) of this one world which we share with him or her. It must be something with which we can to some degree sympathize, in that we can see it as the outcome of rationality, that is, cognitive competence in a broad sense, trying to get to grips with this world. This muted version of Charity may be a far cry from a claim of massive agreement and general correctness, but it is not negligible.

Having thus thrown out the early version of the Principle of Charity and summarized what seems important in the later version, let us now turn back to the other question we have been pursuing and ask whether there is anything in the Principle, as now understood, to raise objections from those who hold other, for example functionalist, views about radical interpretation.

The anti-dualist strand, with its emphasis on the 'externalist' idea that the content of a meaningful item is to be, in part at least, fixed by its context (for example, external causal links),

is thoroughly congenial. (For more on the many varieties of externalism see McGinn, 1989.) Some theorists explicitly reject the idea of meaning holism (see, for example, Fodor, 1987, ch. 3; Fodor and Lepore, 1992). But most functionalists would have no difficulty in endorsing this view also. The central functionalist idea is that psychological terms are elements in some folk proto-theory for explaining behavior; their meaning is explained by reference to their explanatory roles in this theory *vis-à-vis* observable behavior and, importantly, *vis-à-vis* each other. The holist idea of linking content to place in some suitable pattern seems a natural development of this. For such a functionalist, just as for Davidson, rationality, the existence of appropriate inferential and content links, is built into the very nature of the psychological. (See Evnine, 1991, pp. 111–112.)

Where, then, could any clash arise? The crucial question is this. Can the key notion of rationality be given at some level a naturalistic, such as a physical, unpacking; or is it centrally a normative notion of a kind which resists such capture? It would be generally agreed that it is normative; it has to do with thinking as one ought, that is, in such a way as to promote the goals of thought. But this does not preclude the existence of a non-normative equivalent. To use a familiar old example, a knife's being good may, given the acknowledged purpose of knives and the causal facts about the world, amount to its having certain physical properties (of weight, shape, sharpness, and so on). Is there something describable in the language of the natural sciences which in a similar sense is what rationality 'amounts to'?

Some may think that we already have such a thing, and that it is given by an amalgam of the (syntactic) rules of inference provided by (a favored) deductive logic, inductive logic, and decision theory. This, however, seems over-optimistic, given the disputes, paradoxes, and unclarities in these subjects. We also need to remember that acquisition of knowledge about the universe does not always take the form of adding empirical information within a fixed conceptual and logical structure, but may involve modification of concepts and hence of patterns of inter-judgmental linkages (consider non-Euclidean geometry, Einsteinian revelations on space and time, and so on). We are not in a position to say that there are no more conceptual upsets ahead; so we cannot now plausibly claim that we know, definitively and completely, what rationality amounts to.

But all the same, is there such a thing as what it amounts to? This is a very close relative of the question that arose above as to whether any notion of analyticity is defensible (see Chapter 23, ANALYTICITY) and, connectedly, of whether there is some limit to the 'suitable settings' which meaning holism requires. Obtaining a reasoned answer to these questions could well require us to have a view on such things as whether there is one complete and final truth about the universe and one set of concepts which that truth demands for its expression, whether there is any hope of human beings attaining that truth, whether (or in what sense) we could be rational if we were constitutionally debarred by the structure of our minds from attaining it, and what the connection is between rationality in theoretical matters (arriving at the truth) and rationality in practical matters (arriving at good decisions). Those who favor an ultimately physicalist account of rationality will incline to assume something optimistic about the possibilities of disentangling theoretical from practical reason and arriving at the complete truth about the universe, while others will be skeptical on these matters. Some skeptics, like Davidson, seem to think that it is in principle impossible that there should be a physicalistic unpacking. Other skeptics, like the instrumentalist Dennett, seem to think that there is such an unpacking, but that our finitude constitutionally debars us from realizing it and consequently our 'rationality' and 'thought' are merely useful fictions.

We can return here briefly to tie up one loose end, namely why Davidson's proposal has, as remarked towards the end of §3, a behaviorist flavor. We can see now that it is not an attractive option for one who is skeptical about a naturalistic unpacking of 'rational' to appeal to internal structures. If there was a fixed structure to rationality then there would be some fixed set of thoughts associated by meaning holism with any given thought, namely that set which the one and only true rationality requires it to be linked with. And it would be natural to insist that a subject who has the thought must contain some physical realization of (at least some part of) the relevant set and its supporting causal linkages. So, on this view, internal mechanisms would be important. But, on the other hand, if there is no fixed structure of rationality, then it is unclear what importance internal mechanisms could have. The only thing that can matter is whether the totality of utterances and behavior can be redescribed in terms of some one of the (perhaps indefinitely many and exceedingly various) rational psychologies. Any investigation into the inner mechanisms which subserve the intelligible behavior must follow after the attempt to make sense of that behavior. The presence of inner mechanisms cannot be used as a separate and prior constraint on whether a subject possesses a certain thought. (Compare here Davidson's rejection of psycho-physical laws in 1980, essay 11.)

5 Indeterminacy of Meaning, Holism, and Molecularity

We have so far been presenting most of our theories, Davidson's included, as though they were straightforward accounts of what non-semantic facts constituted some semantic fact. But we must now grapple with a final complication, namely that the Davidsonion approach seems to imply indeterminacy (1984, pp. 100–101, 153–154). On his view, to say that a noise has a certain meaning is to say that a subject's behavior can be systematized by a certain kind of theory. But the crucial problem is that there is no guarantee that there is only one way of systematizing a given body of behavior. The assignment of meanings to individual moves or noises is merely a record of the fact that the behavior as a whole can be arranged in a certain sort of pattern. But the fact that the pieces of behavior can be arranged in one pattern cannot rule out the possibility of arranging them also in another one. Consider as an analogy the pieces of a jigsaw. We are used to unique-arrangement jigsaws. But there is no conceptual necessity to this, and an ingenious toy-maker could manufacture (perhaps already has manufactured) multiple-arrangement ones. To label an utterance 'a saying that it is raining' is, on the Davidsonian story, like labeling a jigsaw piece 'a mountain summit piece.' In other words, such a labeling tells us that there is at least one overall satisfactory arrangement in which the utterance or piece could play the designated role. But, to re-emphasize, that is no conceptual bar to the existence of another arrangement in which it plays another role. Indeed Davidson goes further and endorses an argument designed to prove that if there is one adequate linguistic interpretation then there must be alternative satisfactory interpretations. His argument (1984, essay 16) is a close relative of some given by Quine (1960, ch. 2; 1969, essay 2). (See also Chapter 26, INDETERMINACY OF TRANSLATION, and Chapter 27, PUTNAM'S MODEL-THEORETIC ARGUMENT AGAINST METAPHYSICAL REALISM; Dummett, 1975; Heal, 1989.)

We could embrace this conclusion and the anti-realist implications which it has for the notion of meaning. But many philosophers find this conclusion intuitively incredible (such as Lewis, 1983, p. 118). We may note two reasons at least for being unhappy with it. The first

is that it seems to threaten the possibility of a realist metaphysical stance in general. (For more detailed arguments to this effect see Heal, 1989, ch. 6.) The second reason is that it undermines our central notions of deliberation and reason-giving. Let me expand on this a little.

We take it for granted, pre-philosophically, that we are capable of arriving at new thoughts by rational inference from our current thoughts, for example by working out what further things are certainly or probably true of the world, given what we already know. To use the jigsaw model, we think of ourselves as, in part, self-building jigsaws, where gaps get filled in or new pieces are added round the edge in the light of the parts of the scene already pictured. But on Davidson's story existing pieces do not have determinate content of the kind which would enable them to be the rational bases for such extensions. On his view, the contents they are to be assigned await determination in the light of the later pieces. The patterns to which we must look in assigning meaning are patterns spread out across time, including the future, and not merely across space. Thus features of later utterances, features which fix what overall patterns they and the earlier ones can form, are partly constitutive of the earlier utterances having the meanings they do. To put matters very picturesquely, the meaning of an individual utterance is not fully present in it at the time when it occurs, but exists, in part, in the future. What goes on now is such that it could have one meaning in the light of one line of future development, and would have another given some alternative.

Now suppose that we want an explanation of the appearance of some later pieces and we want an explanation which is causal or quasi-causal, in the sense that it has to do with the development of some process through time and explains later stages by citing conditions wholly present at earlier times. It is a consequence of the Davidsonian view (as sketched immediately above) that such an explanation cannot invoke the notion of meaning, because the meaning is not, on that story, present at the time of the utterance to do any causing. Common sense, however, is strongly committed to the possibility of such meaning-invoking and quasi-causal explanation. It is thus committed to what Dummett calls 'molecularity' in a theory of meaning – that is, the idea that grasp of individual concepts (and relatedly the having of determinate individual thoughts into which those concepts are assembled) has some real ontological and explanatory priority *vis-à-vis* the total assemblage of thoughts at which a person arrives (Dummett, 1975). Davidson's holism precisely denies this. So, somewhat paradoxically, Davidson's strong insistence on the rationality of thought as it is spread out through time threatens to deprive us of any dynamic rationality in determination of our futures.

It is the commonsense conviction of molecularity which gives such power and attractiveness to those functionalist theories which emphasize the causal role and determinate nature of inner structures. So one strategy for avoiding the unwelcome indeterminacy would pursue those questions about the nature of rationality which were mentioned at the end of the last section. Such a strategy would also emphasize the importance of determinate causal connections between aspects of the world and states of persons in fixing semantic relations. The hope would be that some acceptable naturalistic theory, using these kinds of materials, can be built. (For more on semantic naturalism, see Chapter 8, A GUIDE TO NATURALIZING SEMANTICS.)

But there is a different move which has been proposed by philosophers influenced by Wittgenstein and skeptical of the success of the naturalistic program (see McDowell 1981; 1982; 1984; Heal, 1989; Mulhall, 1990). They propose rejection of the initial assumption made in §1, which grounded the whole search for a theory of radical interpretation, that

possession of meaning had to be an inferred or constructed state of affairs and is such that it cannot be simply observed. Let us turn to look at this more closely.

It is surely true that we could be in a situation of needing to engage in something like 'radical interpretation.' That is to say, we could be (a) confronted with some complex moving physical object, which might plausibly be taken to be a thinking, talking creature but (b) not yet certain that the creature is indeed a thinker or talker. In such a case there is nothing for it but to assemble what information we can about the creature's behavior and circumstances – information which can be stated without commitment on what it thinks and means, because *ex hypothesi* we do not as yet have firm views about this – and to see what we can conjecture.

But it does not follow immediately from this that meaning is always and essentially a theoretical or inferred matter. Consider a parallel case. I may be confronted by an array of colors and shapes, but unclear as to whether I am seeing a material object. I may then try to assemble facts about the nature of the array and how it changes under various circumstances, in order to help me decide. These facts will be statable without commitment to a view about whether I am seeing an object and/or its nature. We need not conclude, however, that sense-datum theories in their classic form should be resurrected, and that material-object statements should be seen as inferred from or constructed out of sense-datum ones. One crucial idea in seeing that it need not follow is that the investigation of sensory experience will often itself presuppose facts about material objects and our uncontroversial perception of them. For example, it may take the form of seeing what happens *when I put on my spectacles* or *when I move my head*. It is extremely doubtful that we can, in turn, take these conditions to be inferred from or constructed from sense data: and if they cannot, what we arguably have is a conceptual scheme in which both material-object and perceptual-experience judgments are, in different and interlocking ways, 'observational,' and in which neither can be regarded as more fundamental than the other.

Could it be the case that some analogous possibility holds for meaning? On such a view, claims about physical items, with their causes, circumstances, patterns, and so on, would have conceptual links with claims about meanings (just as claims about perceptual experience have conceptual links with claims about material objects), but the latter would not be reducible to the former. And both would be fundamental and observational elements of our conceptual repertoire. On such an approach, it might be possible to combine respect for the normative and holistic elements Davidson stresses with the molecularity and determinacy to which common sense is committed (see McDowell 1981; 1982; 1984; 1986; Heal, 1989).

It is, however, becoming clearer than ever that our questions about the nature of meaning and the possibility of radical interpretation are linked with other fundamental philosophical questions. Of the views sketched in this chapter, different ones will seem attractive, depending upon one's sympathies on certain basic matters; and adjudication between the options discussed is possible only in the light of the persuasiveness of large-scale philosophical positions.

Postscript

ALEXANDER MILLER

Jane Heal's entry discussed the relationship between Davidson's "Truth and meaning" papers (essays 1–5 of Davidson, 1984) and his "Radical interpretation" papers (essays 9–12 in the same volume). In this postscript, we look briefly at a third set of papers by Davidson in which radical interpretation is central. These might be called Davidson's "anti-convention" papers: we'll look in particular at Davidson (1986) and Davidson (1992).[1]

1. Davidson's leading idea in the "Truth and meaning" and "Radical interpretation" papers was, very roughly, that we can make headway in the philosophical examination of the notion of meaning by constructing formal theories of meaning for natural languages, where these theories take the form of empirically verified Tarski-style theories of truth-conditions constructed in accordance with the Principle of Charity. Clearly, the notion of a natural language as such occupies a central place in this account, and one might expect the idea that speakers master the same language to play a role in explaining how they are able to communicate with each other. Moreover, the rules shared by competent speakers of a language are naturally thought of as *conventions*. For example, in the context of a discussion of Davidsonian theories of meaning, speaking of semantic primitives – expressions assigned proper axioms within Davidsonian theories – Crispin Wright comments:

> I do not think that we can attach any content to the supposition that such an expression has a meaning except insofar as meaning is thought of as constituted, at least in part, by *convention*. (Wright, 1986, p. 211)[2]

Startlingly, Davidson rejects all of these ideas. He writes:

> [T]here is no such thing as a language, not if a language is anything like what many linguists and philosophers have supposed. There is therefore no such thing to be learned, mastered or born with. We must give up the idea of a clearly defined shared structure which language-users acquire and then apply to cases. (Davidson, 1986, p. 107)

He describes the conception of a language he opposes as follows:

> [I]n learning a language, a person acquires the ability to operate in accord with a precise and specifiable set of syntactic and semantic rules; verbal communication depends on speaker and hearer sharing such an ability, and it requires no more than this. (Davidson, 1994, p. 110)

And he rejects the idea that the notion of convention plays an essential role in explaining linguistic communication:

> [W]e should give up the attempt to illuminate how we communicate by appeal to conventions. (Davidson, 1986, p. 107)

2. Davidson considers a range of abilities possessed by competent speakers: abilities to interpret malapropisms, to understand garbled or incomplete utterances, to interpret unfamiliar words or phrases, to correct slips of the tongue, and so on. He argues that such phenomena threaten the idea that linguistic competence consists in command of a language governed by shared rules and conventions that have been learned in advance. In all of these cases, command of a language – so construed – is neither necessary nor sufficient for communication.

Mrs Malaprop intends that her utterance of "This is a nice derangement of epitaphs" be interpreted by me as true if and only if this is a nice arrangement of epithets. Despite having no theory that would allow me to interpret the utterance as she intended – according to the theory I bring to the occasion, it is true if and only if this is a nice derangement of epitaphs[3] – I grasp perfectly well what she intended to say. Mrs. Malaprop and I being party to shared rules and conventions is neither necessary nor sufficient for us to communicate successfully.

Likewise, consider Donnellan and MacKay, two philosophers debating whether the former holds a "Humpty Dumpty" theory according to which a word can mean whatever you want it to mean. At the end of his comments, Donnellan mischievously utters "There's glory for you!" with the intention of being interpreted as saying *there's a nice knockdown argument for you!* Despite the fact that they have no shared theory that assigns the relevant meaning to "glory," MacKay understands perfectly well what Donnellan has said:

> What is common to the cases [Mrs Malaprop and Donnellan] is that the speaker expects to be, and is, interpreted as the speaker intended, although the interpreter did not have a correct theory in advance. (Davidson, 1986, p. 98)

In each case, "the interpreter has adequate clues for the new interpretation," clues that are intentionally provided by Donnellan and unintentionally provided by Mrs Malaprop. In Humpty Dumpty's exchange with Alice, by contrast, Humpty Dumpty fails where Donnellan succeeded, because Humpty Dumpty knows that Alice has no suitable clues to go on.

The alleged irrelevance of shared convention to communication leads Davidson to conclude: "we must pry apart what is literal in language from what is conventional or established" (1986, p. 91). He suggests replacing the association of literal with conventional meaning with what he calls *first meaning*, a notion "that applies to words and sentences as uttered by a particular speaker on a particular occasion" (1986, p. 91). The first meaning of Mrs Malaprop's utterance is *this is a nice arrangement of epithets*, the first meaning of Donnellan's utterance is *there's a nice knockdown argument for you!*, while Humpty Dumpty's utterance has no first meaning.[4]

Davidson suggests that these points generalize: "Mrs Malaprop and Donnellan make the case general. There is no word or construction that cannot be converted to a new use by an ingenious or ignorant speaker" (1986, p. 100). So, in general, communicative success does not depend on speaker and hearer having shared command of rules and conventions learned in advance. If we think of a language as a structure of rules and conventions learned in advance and whose sharing is necessary and sufficient for communication, then, "there is no such thing as a language" (1986, p. 107).

3. Davidson thus rejects the proposition

(A) Shared grasp of rules and conventions is necessary and sufficient for successful linguistic communication.

We'll evaluate Davidson's "malapropism" argument for (A) in §5 below. In this section, we'll briefly consider Davidson's remarks on how his view of these matters relates to those developed in Kripke (1982).

In "The second person" (Davidson, 1992), Davidson represents Kripke's Wittgenstein (KW) as arguing that meaningful language is necessarily social in a sense that is both implausible and stronger than that advocated by Davidson himself. Davidson sees the role that communal agreement plays in KW's "skeptical solution" as adding up to a commitment to (A): KW holds that "speaking a language requires … that more than one person must speak the same language" (Davidson, 1992, p. 114). Moreover, KW "depends on the second person, or a community, to embody a routine which the speaker can share" (Davidson, 1992, p. 121). KW thus embraces (A), a claim allegedly undermined by Davidson's "malapropism" argument.

In attributing (A) to KW, though, Davidson fails to recognize the "skeptical" nature of the solution KW offers to the "skeptical paradox" about rule-following, and as a result he mischaracterizes KW's conception of the sense in which language is necessarily social. Underlying (A) is the idea that shared grasp of rules *explains* successful linguistic communication. This is clearly Davidson's main concern: he writes "The concepts of conventions or rules, like the concept of a language, cannot be called on to justify or explain linguistic behavior" (1992, p. 111). However, this is not something that KW would dispute: since he proposes a "skeptical solution" to the rule-following paradox, KW denies that there are facts about which rules agents are following, and so *a fortiori* denies that there are facts about rules that can play a part in the explanation of linguistic behavior and successful communication. This is clear in Kripke's remarks on the role played by agreement in the skeptical solution:

> On Wittgenstein's conception, [w]e cannot say that we all respond as we do to "68 + 57" *because* we all grasp the concept of addition in the same way … For Wittgenstein, an "explanation" of this kind ignores his treatment of the skeptical paradox and its solution. There is no objective fact – that we all mean addition by "+," or even that an individual does – that explains our agreement in particular cases. (Kripke, 1982, p. 97)

And in his summary of Wittgenstein's view as it struck Kripke, he writes:

> The success of [our rule-following practices] … depends on the brute empirical fact that we agree with each other in our responses [to 'go on' in particular ways]. Given the skeptical argument [for the claim that there are no meaning-facts], this success cannot be explained by the fact that we all grasp the same concepts. (Kripke, 1982, p. 109)

In locating the social nature of KW's view in (A), then, Davidson has gone badly astray.[5]

4. Davidson represents himself as proposing "a weaker and more plausible alternative to Kripke's proposed account of what is required in order to mean something by what one says" (1992, p. 117). As we've seen, this is in part because Davidson erroneously ascribes (A) to KW. But Davidson also fails to see that the preconditions for the possibility of meaning in his own account are of roughly equal strength to those actually imposed by KW.

To see this, consider Davidson's "triangulation" argument concerning the determinacy of concepts. According to Davidson, if we consider a child, say, in isolation, there is no fact of the matter as to whether its uses of the word "table," regularly tokened in the presence of tables, are reactions to, or about, tables as opposed to, say, stimulations of the nerve-endings activated in the presence of tables:

> Why not say that its [the child's] responses are not to tables but to patterns of stimulation at its surfaces, since these patterns of stimulation always produce the response, while tables produce it only under favorable conditions? (Davidson, 1992, p. 118)

Subject to certain conditions, the addition of a second person – an interpreter – to the situation can allow the indeterminacy to be resolved:

> [T]he child finds tables similar; we find tables similar; and we find the child's responses to the presence of tables similar. It now makes sense for us to call the responses of the child responses to tables. Given these three patterns of response we can assign a location to the stimuli that elicit the child's responses. The relevant stimuli are the objects or events we

> naturally find similar (tables) which are correlated with responses of the child we find similar. It is a form of triangulation: one line goes from the child in the direction of the table, one line goes from us in the direction of the table, and the third line goes between us and the child. Where the lines from child to table and us to table converge, "the" stimulus is located. (Davidson, 1992, p. 119)

Moreover:

> [This] kind of triangulation … is necessary if there is to be any answer at all to the question what its concepts are concepts of. If we consider a single creature by itself, its responses, no matter how complex, cannot show that it is reacting to, or thinking about, events a certain distance away rather than, say, on its skin. (Davidson, 1992, p. 119)

The conditions that have to be satisfied in order for triangulation to effect determinacy are that the child and the interpreter have similar natural inclinations to group various worldly items together:

> For [triangulation] to work … *the innate similarity responses of the child and teacher – what they naturally group together – must be much alike*; otherwise the child will respond to what the teacher takes to be similar stimuli in ways the teacher does not find similar. A condition for being a speaker is that there must be others enough like oneself. (Davidson, 1992, p. 120, emphasis added)

Davidson's condition – that there be others with like "innate similarity responses" – is virtually identical to the condition imposed in KW's skeptical solution. In the skeptical solution, the sustainability of the language game in which we are permitted to assert that so-and-so has mastered such-and-such a concept depends on the fact that the individual belongs to a community whose members have the same natural inclinations to, for example, continue the series 2, 4, 6, …, *in the same way* beyond a certain point:

> [O]ur license to say of each other that we mean addition by "+" is part of a "language game" that sustains itself only because of the *brute fact* that we generally agree. (Kripke, 1982, p. 97, emphasis added)

> It is an *empirical fact* that … individuals often are disposed to give responses in concrete cases with complete confidence that proceeding this way is "what was intended" … [T]he success of our practices depends on the *brute empirical fact* that we agree with each other in our responses. (Kripke, 1982, pp. 108–109, emphases added)[6]

Kripke also speaks of "brute inclinations" (1982, p. 112, n. 88) and "unhesitating responses" (1982, p. 86). The fact that members of a community have co-incident primitive inclinations is essentially what Davidson himself is referring to when he speaks of interpreter and interpretee having the same "innate similarity responses." Contrary to what Davidson claims, then, the social conditions he imposes on the possibility of meaning are not weaker than those imposed by Kripke.

5. Returning very briefly to the "malapropism" argument outlined in §2 above, we can raise a doubt as to whether it establishes its intended conclusion even if we grant that Davidson correctly describes the relevant linguistic phenomena. Let's suppose that Davidson

is right when he says that I understand Mrs Malaprop despite the different meanings we attach to "derangement" and "epitaph," and so grant that he is right to claim:

> (a) For any given utterance e that speaker A makes in the presence of speaker B, it is possible that e results in successful communication despite the fact that e contains an expression to which A and B attach a different meaning.

However, what Davidson really needs in order to establish "that there is no such thing as a language" is rather:

> (b) It is possible that: most utterances e made by speaker A in the presence of speaker B result in successful communication despite the fact that e contains an expression to which A and B attach a different meaning.

Moving from (a) to (b) would appear to commit a kind of quantifier shift fallacy: for any given meal I eat, it is possible that I remain healthy despite its consisting solely of a Snickers bar, but this does not imply that it is possible for me to remain healthy on a diet consisting exclusively of chocolate covered peanuts. Likewise, the possibility that some *episodes* of communication are successful despite the absence of shared meaning doesn't entail the possibility of a generally successful communicative *practice* in the absence of shared meaning.

Even if Davidson is right about cases like Mrs Malaprop, therefore, he may not be warranted in moving to the conclusion that successful communication does not require shared meaning, rules, and conventions.[7]

6. In this short postscript we have been able to consider only a couple of the many fascinating issues raised by Davidson's papers on the role played by rules and conventions in linguistic interpretation. A fuller account would need to examine whether his apparatus of "prior" and "passing" theories (Davidson, 1986, p. 101) renders his anti-conventional stance consistent with that of "Truth and meaning." For further discussion, see LePore and Ludwig (2005, ch. 17), and Gluer (2011, ch. 2).[8]

Notes

1 Other important papers in this set include Davidson (1982), Davidson (1989), and Davidson (1994).

2 The similarity between Davidson's ideas on the construction of formal theories of truth-conditions for natural languages and the approach taken in Wittgenstein's *Tractatus-Logico Philosophicus* has often been noted (see, e.g., Kripke 1982, pp. 71–72, n. 60). Interestingly, the *Tractatus* appears to assign a role to convention of a piece with that which Davidson rejects. See, for example, 4.002, where Wittgenstein writes "The tacit conventions on which the understanding of everyday language depends are enormously complex" (as translated in Wittgenstein, 1962).

3 Of course, talk of a speaker "having a theory" is for Davidson simply shorthand for the idea that the theory serves to correctly describe his linguistic competence. See Davidson (1986, pp. 95–96).

4 The emphasis on the notion of first meaning as more fundamental than that of shared language is one major bone of contention in the exchange between Dummett (1986) and Davidson (1994).

5 Davidson confesses to ignoring the "skeptical" aspect of KW's view (1992, p. 113, n. 7), but he fails to see that this badly distorts his account of KW's position on the social nature of meaning and rules.

6 In fact, Kripke tries for something weaker than this: so long as the individual is not *considered in isolation*, he may follow rules even if physically isolated (Kripke, 1982, p. 110). If sustained, this would make Kripke's condition even weaker than Davidson's.

7 Davidson's remarks (1994, p. 119) on the "theoretical possibility of communication without shared practices" seems to me to leave the quantifier shift worry untouched.

8 Thanks to Bob Hale, Jane Heal, Ali Hossein Khani, and Daniel Wee for helpful discussion.

Propositional Attitudes

MARK RICHARD

Propositional Attitudes and Philosophy of Language

What are propositional attitudes? An informal answer is that they are relations – like belief, fear, hope, knowledge, understanding, and assuming – between minds and propositions. A somewhat sharper answer identifies them with the sort of mental state that (normally) has truth-conditions (or the like) in virtue of being representational.[1] We can distinguish among propositional attitudes in terms of their differing connections to behavior, to perception, and to one another.

A variety of objections (which for want of space we won't discuss) might be raised to this characterization. Some have wanted to reserve the term 'propositional attitude' for states which are "in principle accessible" to consciousness, or that are "inferentially integrated" with other propositional attitudes (see Chapter 15, HOLISM, and Chapter 12, TACIT KNOWLEDGE, §2). At issue is the status of the states ascribed to us by theories in linguistics and cognitive science.[2] Some say that some perceptual states (seeing a lion dance, for example) satisfy our definition, but are importantly different from propositional attitudes (because they are relations to events or other concrete entities).[3]

Some of the contention and research surrounding propositional attitudes and sentences ascribing them (call the latter APAs) results from their importance to epistemology, philosophy of mind, and action theory. Why has philosophy of language been so concerned with attitudes and their ascription?

Perhaps the primary reason is the view that propositional attitudes are relations to *propositions*. On many views, propositions both are closely related to meanings (and thus critical to an account of linguistic competence) and are what is in the first instance true or false (and so are integral to an account of how thought and talk relates to the world). On the simplest plausible version of this view,

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

(1) Propositional attitudes are binary relations picked out by attitude verbs such as 'believes' and 'says.'[4]
(2) A use of a (declarative) sentence *expresses* a proposition, save in cases in which the sentence is semantically defective, as perhaps are sentences with empty names.[5]
(3) Propositions have truth-conditions and thus truth-values and modal properties such as necessity. A sentence inherits these from the proposition it expresses.
(4) In a use of an APA *a Vs that S*, V is an attitude verb, *that S* names a proposition expressed by S; the ascription is true provided that what *a* names is related, by the relation *V* picks out, to the proposition.[6]
(5) There is an (axiomatizible) account assigning, to a sentence-type S and a context of use c, the proposition that is expressed by S as used in c. This proposition is what's named in c by *that S*.
(6) A sentence's meaning is given by a rule which enables one to tell, given appropriate non-linguistic information about a context or a use (for example, who is speaking, what time it is), what proposition the sentence expresses. To be a competent speaker is to know such a rule.

The spirit of (1) through (4) informs a good deal of what Frege and Russell had to say about language, truth, and thought. Something like (5) informs the work of those of us who count Tarski and Montague along with Russell and Frege as founders of modern philosophy of language.

Call (1) through (5) the *relational account* of attitudes and their ascription. It is a short step from the relational account to the idea that when a sentence is used (literally) to convey information, the information conveyed is the proposition the sentence expresses: the information conveyed by Sam's literal use of S is naturally identified with both what's said by S and (given the relational account) with the referent of the complement clause in a true use of 'In uttering S, Sam (literally) said that T.' Given that the role of a semantic theory is in large part to give an account of how sentences are used to convey information, it follows that a good deal of semantics will be concerned with explaining the association of objects of propositional attitudes with sentences and their uses.[7]

David Kaplan popularized (6); he calls the sort of rule in question the *character* of a sentence (Kaplan, 1977; see also Chapter 38, THE SEMANTICS AND PRAGMATICS OF INDEXICALS). It is controversial in ways that (1) through (5) are not: perhaps a person can be a competent speaker of English in virtue of having syntactic knowledge and a variety of abilities which needn't add up to propositional knowledge of the rules assigning propositions to sentence uses.[8]

Some reject the relational account's implication that semantics is about what's said. For example, Davidson identifies theories of meaning with theories giving a Tarskian account of truth.[9] But even the dissenters recognize in one way or another the importance of another problem posed by attitude ascriptions. This is what Max Cresswell has called the *hyperintensionality* of APAs: Expressions which have the same possible-worlds intension – and so, in general, can be substituted for one another outside of APAs and quotational contexts – cannot be so exchanged in APAs. This anomaly constitutes a second reason why APAs are important to the philosophy of language.[10]

This problem might well be divided into two sub-problems. First of all, what otherwise appear to be logical laws apparently fail when applied to APAs.[11] If the argument from A to B is logically valid, then *If A, then A* and *If A, then B* are logically equivalent, no matter how hairy the proof of the latter might be. So

Donald knows that if A, then B

appears to come from

Donald knows that if A, then A

by substitution of logical equivalents. But few think pairs so related must be equivalent in truth-value. The first problem of hyperintensionality, then, is to explain what transformations within the scope of attitude verbs are logically valid.

Notoriously, proper names of the same thing are intersubstitutable within modal contexts *salva veritate*, but are not in the scope of attitude verbs. For example,

Odile thinks that Twain is dead
Odile thinks that Clemens is dead

apparently needn't agree in truth-value. In fact, even expressions, like 'yell' and 'shout,' which appear to be *synonyms* are not intersubstitutable within the scope of attitude verbs. Tyler may take 'yell' and 'shout' to be synonyms, but think that there are people who understand these expressions – and so have beliefs about yelling and shouting – but who have doubts that every shout is a yell. It is quite plausible that in this case

Tyler thinks that some doubt that all who shout yell

may be true, while

Tyler thinks that some doubt that all who shout shout

is not. But the latter comes from the former by substitution of (apparent) synonyms for synonyms.[12]

That even substitution of apparent synonyms fails within attitude ascriptions presents a *prima facie* counter-example to the claim that natural languages have semantics which satisfy a non-trivial principle of compositionality, on which the semantic properties of a complex expression are determined, in a way which can be spelled out in a finite theory, by the semantic properties of its parts and by its syntax. For synonyms, one would have thought, have identical semantic properties. The second problem which the hyperintensionality of attitude ascriptions poses is that of finding an account of the semantic properties of expressions which provides a satisfactory account of the truth-conditions of attitude ascriptions (and other constructions, of course), while also allowing for a compositional account of the semantics of natural languages.

This last problem has proven remarkably difficult. Indeed, the arguable failure of all attempts to arrive at a satisfactory account of APAs moved Stephen Schiffer (1987) to argue that natural languages simply have no compositional semantics, in the sense of an axiomatizable theory which characterizes the conditions under which a use of an arbitrary sentence of the language is true or false.

The balance of this chapter discusses the prospects for a satisfactory account of the semantics of natural language attitude ascriptions.

Questions about Propositions

Assume for the next few sections that to ascribe an attitude with a sentence of the form *a Vs that S* is to say that (what) *a* (names) bears a relation, picked out by *V*, to the proposition determined by the complement of the verb. Much of the work on APAs centers upon the search for an account of propositions that (married to the just mentioned assumption) underwrites our intuitions about the truth-conditions of attitude ascriptions.

There are three sorts of questions one might ask about propositions. First off is a metaphysical one: What sorts of things are they? Among candidate answers are the claims that propositions are: *sui generis* abstract entities; states of affairs – congeries of objects and relations or constructions out of such; properties – for example, the property a state of affairs has when its obtaining necessitates that it is now snowing in Lille; linguistic entities – interpreted sentences or utterances, for example.

The metaphysical question is of particular interest if one thinks that propositions must be "intrinsically representational": not only do they possess truth-conditions (and thereby represent), but their representational properties are not derivative. One might think this if one thinks (as Frege did) that the fact that talk and thought is representational is explained in terms of the representational properties of what one "grasps" in thought and talk. One might also infer the "intrinsic representationality" of propositions from the fact that propositions have their truth-conditions essentially, and thus must have them even in the absence of minds and their activities.

Those who think that propositions are intrinsically representational have offered a variety of accounts that are supposed to explain how there can be such things. Scott Soames suggests that representation arises in cognitive activity, in particular in the predication of properties and relations. To think snow white is to predicate whiteness of snow; propositions, Soames says, are types of such cognitive events, the proposition that snow is white being the event type of predicating whiteness of snow. On this view, propositions are essentially representational since they are the sort of thing that happens when one represents. Jeff King suggests that propositions are (roughly put) objects and properties standing in the kind of (representational) relations that (for example) Renee and walking away stand in, given the existence of sentences like 'Renee walks away.' Other theorists have given kindred accounts of propositions. [13]

One might wonder why propositions need to be "intrinsically representational" to begin with. Those who think that propositions are sets of possible worlds, ways things might be, or something fact-like ("states of affairs") will deny that propositions are representational in anything more than a derivative sense. What is representational is cognitive and linguistic activity; propositions – that is, the sorts of things picked out by complement clauses – are things we use to classify the states of the things that represent.[14]

Second, there is, as we might put it, an alethic question. The (more or less) standard view of attitudes like saying and thinking is that what is said or thought is absolutely true or false – its truth does not vary across time, place, or taste. The alethic question is: Really? Here are reasons to think that the standard view isn't right. (a) David Lewis claims that objects of thought can't be propositions *cum* things absolutely true or false because one who knows every proposition doesn't thereby know everything there is to know. A world might contain two propositionally omniscient gods, Gary and Ed: each knows that Gary lives in Shutesbury and eats corn, that Ed lives in Leveritt and eats peas, that Gary is tall and Ed is not, and so on. They could, Lewis says, know every proposition and thus know exactly what

world they occupied though neither one knew whether *he* ate peas or corn. Lewis's solution to this puzzle is to propose that the objects of assertion and belief are *properties*, not propositions. For Ed to know that he eats peas is to "self-ascribe" the property of eating peas; for Gary (or Ed) to know that Ed eats peas is for him to self-ascribe the property of being such that Ed eats peas. (b) Some say that facts about (how we report) belief identity and retention show that what is said and thought changes truth-value over time. Suppose Jane sees June in 2013 and thinks 'she's pregnant'; Janine sees June in 2015 and thinks 'she's pregnant.' This seems to imply that when Jane saw June she thought June was pregnant, and when Janine saw June that's what she thought/she thought so too. But since Jane might have been right while Janine was wrong, it appears that the thing each thinks can be true at one time, false at another. (c) A more radical objection to the standard view observes that: (i) the standards for being rich (or round or rotund or…) vary across conversations, so that a use of 'June is rich [for a resident of Rome]' may be true in one conversation, false in another, but; (ii) even when we know that standards so vary, we take she who utters 'June is rich' in the first conversation to disagree with someone who in the second conversation denies it. (i) and (ii) seem to imply that the object of (assertion, belief, and) disagreement is something whose truth varies with the standards or presupposition in a conversation.

The literature on (b) and (c) is too vast to take up here.[15] We will return to Lewis's example and the topic of belief *de se* at the end of this chapter.

Semantics and Structure

I said there were three questions one might ask about propositions. The third is one about the way propositions are related to the sentences that express them. Propositions, we are supposing, are picked out by complement clauses, things like the phrase 'that it's raining.' One would like to know exactly how a proposition is determined by a (use of a) complement clause; ideally, an account that tells us that also tells us the conditions under which two sentences express the same proposition, thereby giving us a handle on propositional individuation. One wants to know what meanings ("semantic values," in the jargon of semantics) must be assigned to simple expressions (and syntactic structures) to determine propositions. Finally, one wants to know whether (the) propositions (an adequate semantics assigns to sentences) turn out to have structure (or at least individuation conditions) like that of the sentences that express them.

Begin with the last issue. A belief or assertion partitions possibilities into two classes, those in which it is true and the rest. One picture of propositions identifies them with such partitions. The view that propositions are sets of possible worlds is a version of this picture; so is the picture of propositions as sets of situations. Unlike most views which read the structure of a sentence onto the proposition it expresses, such views allow that difference in structure is not a bar to sentences saying the same thing: the claim that A&(B&C) is the claim that B&(C&A). And since a non-linguistic mental state may (in virtue of its relations to evidence and behavior) partition possibilities, this view makes ascription of belief to non-human animals relatively unproblematic.[16]

However, logically equivalent sentences are true in the same worlds. When A is a logical consequence of B, the worlds in which B is true are the worlds in which A and B are true. So it is impossible to know that B without knowing that A and B. The identification of propositions with sets of worlds does not solve the problem of hyperintensionality.

There have been some ingenious attempts to reconcile the idea that propositions are sets of worlds with the thought that one can believe what's said by

(a) 1 + 1 = 2

without believing what's said by

(b) 587/16 < 37.

Many depart from an observation of Stalnaker's that possible worlds play two roles in determining what is said.[17] Worlds provide the situations relative to which a sentence or thought token is true or false; they also help determine the semantic values of sentences and their parts. A toy example: Suppose we have fixed the reference of 'Hesperus' as the heavenly body that rises at position p, of 'Phosphorus' as the body that rises at position p′. In the actual world w, Venus rises at both p and p′, but in another world w′ different bodies may rise at p and p′, and in a third w″ (let's say) it is Mars that rises at both. In this case 'Hesperus is Phosphorus' determines a necessary truth at the actual world and at w″, a necessary falsehood at w′. It also, Stalnaker suggests, determines a "diagonal proposition," one true at world w* iff the sentence, interpreted in w*, is true at w*. This is a contingent proposition, true at w and w″, false at w′. Stalnaker suggests that in certain cases the content of a thought or assertion realized by a token of the sentence is the diagonal proposition. A general application of this proposal offers a way of simultaneously respecting the ideas that (for example): names rigidly designate their bearers; propositions are unstructured sets of worlds; although (a) and (b) interpreted according to "straightforward semantic rules" are true in the same possible worlds, they can express different thoughts.

Though ingenious, it is not clear that such views solve the underlying problem. For one thing, they are committed to the idea that anyone who knows that 1 and 1 is 2 knows that 587/16 < 37. True, on the above approach there is *an understanding* of 'anyone who knows that 1 and 1 is 2 knows that 587/16 < 37' on which it is false, at least given that sometimes *a knows that S* ascribes belief in the diagonal proposition determined by *S*. But one has to wonder why we should think that *any* construal of that sentence is true. Furthermore, such views tend to make the relation between the objects of belief and the bearers of truth and necessity obscure. It is, after all, necessary that 587/16 < 37. But then how can it be (sometimes truly said) that when John said that 587/16 isn't less than 37, he asserted something contingent – though, of course, it's not contingent that 587/16 < 37?[18]

Headway can be made if we assume that propositions have a structure which reflects the structure of the sentences which express them. If what's said by a sentence is individuated in terms of contributions made by the parts of the sentence, then logically equivalent sentences may, when they have different structures or their parts make different contributions, say different things.[19]

Given that propositional structure is derived from or at least reflected by sentence structure, it seems that the main problem an account of propositions has to answer is: What sorts of things are the constituents of propositions? A natural first answer is that they are the workaday semantic values of expressions: individuals, properties and relations, and things corresponding to connectives and logical operatives, if we select values as Russell would have us; possible-worlds intensions, if we select such values as does the possible-worlds semanticist.

This answer, however, seems to run into problems if we assume that what a sentence says is (roughly speaking) determined by "putting" semantic values contributed by expressions into the appropriate positions in a structure contributed by the sentence. There is no difference in the propositional structure contributed by 'Twain is dead' and 'Clemens is dead'; neither is there is any difference in the semantic values of the sentence's parts, on either of the above accounts of semantic values.[20] But it certainly seems that one can believe what one of the sentences says while not believing what the other does.

(Neo-)Russellianism and Fregeanism

Some say that this is wrong – you *can't* believe that Twain's dead without believing that Clemens is, for the proposition that Twain's dead just is the proposition that Clemens is. Such "direct reference" (sometimes called Russellian, Millian, or naïve) accounts of propositions have gained currency in good part as a result of arguments by Donnellan, Kripke, Putnam, and Kaplan against Fregean and descriptional accounts of the semantics of proper names and natural kind terms.

At the core of many of these arguments was the simple but compelling observation that, for example, what's said by 'Twain is dead' is, of necessity, true if and only if *Twain* is dead; what's said by 'Clemens is dead' is, of necessity, true if and only if *Clemens* is dead; and thus the truth-conditions of the claims that Twain is dead and that Clemens is dead are the same.[21] This makes it implausible, given the identity of what a sentence says and the object of the belief it expresses, that there is any (contingent) truth-conditional content which distinguishes the object of the belief that Twain's dead from that of the belief that Clemens is. But if there isn't this sort of difference between the objects of the beliefs, one might argue, it is not clear that there's any difference at all between them.[22]

Such arguments seem to give the lie to views of thought and its ascription like those held by Frege. Relevant to our present concerns are the following of Frege's views: Sentences and their significant parts have both *reference* and *sense*. An expression's reference is (roughly) what would nowadays be called its extension; its sense a "way of thinking" or "mode of presentation" of its reference. Frege's examples of senses of proper names are often given by associating definite descriptions with names, encouraging the widespread view that sense corresponds to some sort of descriptive conceptualization. In any case, it is the sense of an expression that is responsible for its having whatever reference it has. Senses are also the objects of propositional attitudes and the references of complement clauses. Thus, *a believes that S* is true just in case *a* bears the belief relation to the sense named by *that S*. The simple but compelling observation implies that the thought that Twain is dead cannot be identified with the thought that the F (for any F contingently true of just Twain) is dead. And this suggests that names are not synonymous with descriptions and do not have Fregean senses. But then it seems that the only contribution a name might make to what a sentence says is its referent. Given this and plausible principles of compositionality, the direct-reference view seems to follow.[23]

One might argue that if a speaker sincerely and understandingly dissents from a belief ascription, saying *I do not believe that S*, she must be correct about this; but this would not be so if the direct-reference view were correct. However, dissent does not imply disbelief. Suppose that A is watching B, who is across the street on the phone. A is also speaking to B on the phone, though A is not aware that the person seen is the person spoken to. Suppose

that A can truly say, pointing across the way, *I believe that she is happy*. Then B can say, to herself or through the phone, *The man watching me believes that I am happy*. If B can thus speak truly to A, A can speak truly, through the phone, to B, saying, *The man watching you believes that you are happy*. Since A can also say truly, *I am the man watching you*, a use of *I believe that you are happy* by A would also be true, even though A, we may suppose, would dissent.[24]

Direct-reference views, of course, conflict with strongly held intuitions of speakers. Speakers do not see the facts that Hesperus is Phosphorus, and that the ancients knew that Hesperus was Hesperus, as giving us any reason at all for thinking that the ancients knew that Hesperus was Phosphorus. Advocates of direct reference counter that these intuitions can be explained by distinguishing between what a sentence use literally says and what it might convey by non-semantic means. They suggest that (a) to have a propositional attitude is to be related to a Russellian proposition "under" a way of apprehending such; (b) while information about how a proposition is believed is typically conveyed by an APA, it is conveyed as a conversational implicature or via some other pragmatic, non-semantic, mechanism; (c) speakers' intuitions, while sensitive to the information a sentence use conveys, are often unable to distinguish between what is conveyed as a matter of truth-conditional content and what is conveyed pragmatically. (a) is made plausible by appeal to the above-mentioned attacks on Fregeanism. Suggestion (c) is independently plausible. And the distinction drawn in (b), between semantically and pragmatically conveyed information, is one which any comprehensive theory of language will have to draw. So unless we have an account that handles the data better than the direct-reference account, we should adopt it.[25]

I don't find this line of defense satisfactory, for it forces us to say that attempts to explain or predict behavior by ascribing propositional attitudes, if taken literally, *cannot* be successful. For it is the "way" a belief or desire is held that is relevant to its role in governing behavior, not (merely) its Russellian content. That Smith wants Twain dead, and that he believes that if he shoots, Twain will die, gives us not the slightest reason to think that Smith will shoot, given that the APAs are to be understood as the direct-reference theorist would have us understand them. For Smith might hold the desire under "Twain is dead," hold the belief under "if I shoot, then Clemens will die," and not accept "Twain is Clemens." Given the central role behavior explanation has in the practice of ascribing attitudes, it seems asking too much to ask us to relegate such explanations to the realm of pragmatic by-effects.[26]

A Fregean might simply concede to Kripke, Kaplan, Donnellan, and the rest that sense does not determine reference or the modally relevant properties of an expression.[27] She could still say that expressions have sense. She might say that sense is semantically irrelevant *except* in linguistic contexts sensitive to it: propositional-attitude constructions, those created by 'seek,' 'imagine,' and other such verbs, and a few others (e.g., 'means that'). Perhaps as an ecumenical gesture, the Fregean could allow that in such contexts expressions stand for something cobbled out of sense *and* reference. For example, perhaps 'Twain' in my use of 'Flo thinks that Twain is Clemens' would have as a reference the pair <Mark Twain, the sense I associate with 'Mark Twain'>. Thus, it might be said, we have the advantages of a Fregean account of attitude ascriptions without the drawbacks of an implausible account of reference.

Sense, however, is idiosyncratic, in so far as speakers may use a name to refer to an individual, but associate quite different senses with it. Suppose you have a belief you express with 'Frege was German.' I should be able to ascribe it to you by echoing you, saying, 'You think that Frege was German.' But if the complement clause names the thought *I* express

with 'Frege was German' it seems that the ascription won't be true, since you, having a different sense for 'Frege,' don't believe *my* thought that Frege was German (see Kripke, 1979; Richard, 1987).

One might suggest that in *a believes that S*, the complement names a sense which *a* associates with S. One problem with this is logical: It renders the argument *You think that Frege was German; Jo thinks whatever you do; so Jo thinks that Frege was German* invalid, since the complement now designates flaccidly. One might hold that a use of *that S* names the speaker's sense for S, and say that *a believes that S* is true iff *a* has a belief object that is *similar* to the one the complement names. But this again runs afoul of the fact that I can report the beliefs of others by echoing their words, as when the other expresses belief saying, 'Frege was German,' and I say, 'the other believes that Frege was German.' For I can do this even when the other thinks of Frege in ways quite unlike the way in which I think of him.[28]

Even if the Fregean account of attitude *ascription* is in error, a Fregean might say, still, attitudes *themselves* are relations to the sort of thing which Frege had in mind when he spoke of sense. But what are senses? A goodly number of Fregeans have suggested that at least in the case of proper names the notion of sense can be cashed out in terms of the notion of a *mental file or dossier*.[29] Roughly, the idea is that a way of thinking of something is a way of keeping track of, or a locus of information about, it. On this conception of sense co-referential names will have the same sense when their user directs information "tagged" with either to the same locus of information; thus, names a speaker knows to co-refer will typically have the same sense.

Whether this be Frege's notion or not, it is unclear that propositional attitudes can be individuated in terms of it. For one thing, assertions seem much more finely individuated: to say that Twain sleeps is not to say that Clemens does, even if speaker and audience have a single Twain/Clemens dossier. (For what one says does not shift simply because one's audience does; but one who understands what I say with 'Twain sleeps' and 'Clemens sleeps' may find only one claim informative.) Since there is pressure to identify the objects of beliefs and assertions (we can say what others think and think what others say), such considerations also count against individuating beliefs in terms of such a notion of sense.

Some contemporary Fregeans have argued that Frege's view of sense and reference is quite different from the view criticized by Kripke, Kaplan, and others. They say that the sense of a proper name is tied to what it presents in such a way that it is impossible for the sense to present anything other than that referent. As Gareth Evans explained the idea, my way of thinking of an object is characterized by describing how that mode of thought relates me to it; for you to think about something in the same way, the same description has to apply to you (save that references to me are replaced by references to you). Since the description refers to the object of thought, the way of thinking is one whose use (and thus existence) depends on its object.

A fanciful example: My sense for 'Frege' relates me to Frege because it is associated with (or is) information my teacher, Terry Parsons, conveyed to me, and which he gained by talking to Frege. It is impossible for such a description to be true of anyone unless Frege exists (and unless Terry Parsons exists, for that matter). So it's not possible for someone to think of something with my sense for 'Frege' unless these objects exist. Furthermore, if the description applies to you, it applies because you think of *Frege*, so my sense for 'Frege' can't pick out anything but him.[30]

It is commonly thought that a *virtue* of Frege's view, over that discussed in the last section, is that it can assign a thought to a sentence with an empty name, without committing itself

to the existence of a reference for the name. On Evans's account a name without reference is without sense, since there is no *x* such that the name represents a way of thinking of *x*. So sentences in which a referenceless name occurs have no sense, either. Whether this is ultimately objectionable depends in part on whether we should suppose (for example) that the same sort of explanation of Smith's behavior is to be given, when (1) Smith *sees* a cat, thinks "that's nice," and is moved to pet, and (2) Smith *hallucinates* a cat, thinks "that's nice," and is moved to pet.[31]

Attitudes, Utterances, and Sentences

If ascribing an attitude is not relating someone to a Russellian proposition or Fregean thought, what is it? Perhaps in ascribing attitudes we are talking about linguistic entities – sentences or utterances, for example. If so, we can in principle account for hyperintensionality. Even if 'I shout' and 'I yell' are synonymous, they are different sentences; to say that Mary is related to one needn't commit us to her being related to the other. Another attraction of such views is ontological: those suspicious of properties, possible worlds, or other "intensional entities" have hoped to make extensional sense of the attitudes by seeing them as relations to sentence tokens, utterances, or some other linguistic ersatz for propositions.

One well-known linguistic account of APAs is Davidson's paratactic one (Davidson, 1969). Davidson took the 'that' in 'says that' as a demonstrative, picking out the ensuing sentence-utterance. An indirect-speech report says that some utterance of its subject *samesays* the demonstrated utterance, with samesaying one or another relation of synonymy. Thus

[D] Derrida said that man is irrational

has the form and truth-conditions of

[Dl] Some utterance of Derrida's samesays that. Man is irrational.

where the demonstrative names the utterance of the sentence following. It is on Davidson's view no more the task of semantics to explicate the samesaying relation than to explicate relations picked out by other transitive verbs.

Lepore and Loewer observe that we can generalize this account to other propositional attitudes, by quantifying over states which stand to those attitudes as utterances stand to sayings (Lepore and Loewer, 1989). For example:

[S] Searle thinks that glass is transparent

has a logical form suggested by

[S1] There's a belief of Searle's which has-the-same-content-as that. Glass is transparent.

They suggest identifying belief states with neural ones.

The paratactic account is often thought to be committed to a manifestly false account of truth-conditions. If [D]'s truth-conditions are those of [Dl]'s, then [D] cannot be true unless

a particular English utterance exists, for [Dl] involves reference to such. But no utterance is such that Derrida could say that man is irrational only if it exists. Lepore and Loewer reply that u may samesay u′ even if u′ does not exist. This requires that utterances have their semantic properties essentially. If they are physical events, this may not be plausible. (For another response, see the end of this section.)

The paratactic account is fairly non-conservative as far as logical intuitions go. Burge points out that even arguments of the form *a believes that A. So, a believes that A* are not formally valid on Davidson's account, since the demonstratives they supposedly contain must vary in reference (Burge, 1986). The account has also been criticized on syntactic grounds, as it makes binding like that occurring in 'Every boy said that he is a fine fellow' mysterious.[32]

Perhaps the best-known account of ascriptions like [D] and [S] on which they are ascriptions of relations to sentence-types is Carnap's (1946). The account makes use of the notion of intensional isomorphism: roughly and slightly inaccurately, sentences are intensionally isomorphic provided they have the same syntactic structure and their simplest interpreted constituents have, pointwise, the same possible-worlds intension. Carnap's suggestion was (roughly) that [D] is true provided

> [D2] Derrida assertively uttered a sentence intensionally isomorphic to 'man is irrational'

[S] is true if, roughly, Searle is disposed to assent to some sentence intensionally isomorphic to 'glass is transparent.' These proposals are members of two large families of sententialist accounts of such ascriptions, other members being obtained either by replacing intensional isomorphism with some other relation between sentences (translation, for example), or by replacing the relation the subject of the attitude has towards the sentence most directly realizing her belief – replacing *is disposed to assent to* with *has a neural copy of*, for example.[33]

Church's objections to Carnap's proposal are taken by many to be decisive (Church, 1950). Church had two objections to Carnap. First of all, he complained that [D2] did not "convey the same information" as [D], since one gives the content of Derrida's assertion without revealing his words, while the other gives his words but not the content. Church reinforced the point by observing that literal translations of [D] and [D2] into German would clearly convey different things to a German speaker.

If we take Carnap's account as an attempt to spell out truth-conditions (thought of as sets of possible worlds or truth-supporting situations), this objection simply misses the point.[34] There is no reason to suppose that an illuminating account of the truth-conditions of (a use of) a sentence S and (the use of) S itself will convey the same information. For example, a correct account of the truth-conditions of 'some dogs bark' is given thus:

> Some of the things to which 'dog' applies are things to which 'bark' applies.

But this does not convey the same information as 'some dogs bark.' Indeed, an illuminating account (say, in terms of structure) of what proposition S expresses will typically fail to convey the same information as S.

Church's other objection to Carnap's account was in essence this. Example [D] and its German translation are not intensionally isomorphic, since they involve reference to different expressions (of English and German respectively). So 'Leo thinks that Derrida said that

man is irrational' and its German translation can be expected to vary in truth-conditions or even truth-value – Leo might be disposed to assent to an isomorph of [D] without being disposed to assent to an isomorph of its German translation. The objection assumes that a sentence and its translation can't diverge in truth-value, but surely this is false. 'He thinks Phil's a groundhog' and 'He thinks Phil's a woodchuck' may diverge in truth-value; but they are both translated by the same sentence in French, which has but a single word for the woodchuck.[35]

Church did point out a serious problem for *Carnap's* version of sententialism, but it is not clear that he uncovered a problem with *every* version of sententialism. For example, it is not clear why a sententialist who held

> *a believes that S* is true iff what *that S* names (the sentence S) translates a sentence "in a's belief box"

should be perturbed by Church's objection.

Some generic objections to sententialism should be mentioned in passing.[36] It's commonly alleged that sententialism is defeated by the fact that a sentence can mean different things in different languages. For all we know, there is a language L in which 'pigs fly' says that dogs bark. Thus 'pigs fly' translates (into L) a sentence ('dogs bark') which is in my belief box. Thus, on the account of the truth-conditions just displayed, it is true that I think that pigs fly, since the sentence 'pigs fly' translates a sentence realizing one of my beliefs. But I don't think that pigs fly.

There are natural ways of individuating sentences on which such objections have no force. We might identify words with sets of utterance tokens by speakers. English's 'pig' then turns out to be the set of all English 'pig' tokens. If sentences are structured collections of words, the objection fails, since L's words and English's words are surely different.

The second objection is this: If propositions are sentences, then that Smith thinks that fleas are disgusting entails that the sentence 'fleas are disgusting' exists. But Smith might have the belief without the sentence existing. A sententialist needn't accept the claim about entailment. Presumably there is a cross-world relation, *sentence S as used in w translates sentence T as used in w′*. S (in w) stands in this relation to T (in w′) in virtue of uses of S in w being similar in appropriate ways to those of T in w′. Such similarity does not require that S in fact exist in w′. (The contents of my bathtub don't have to exist in w′ in order for the underlying kind of my bathtub's actual contents to be the same as the underlying kind of some sample of liquid in w′.) A sententialist who endorsed a translational account of attitude ascription might simply say that *a believes that S* when used at a world w is true at world w′ just in case (1) there is at w′ a sentence T which realizes at w′ one of a's beliefs, and (2) S as used at w translates T as used at w′.

Semantic versus Psychological Sententialism

The view, that what *that S* provides in *a believes that S* is (individuated in terms of) a sentence, is a view about the semantics of belief ascription. It must be distinguished from the view that beliefs and other attitudes are realized in the mind or brain by states which are sentence-like in important ways, *psychological sententialism*, as it might be called.

On this view, the psychological states which realize propositional attitudes (a) have syntactic structure and parts with semantic properties like those of natural-language sentences; (b) have truth-conditions which can be assigned by something like a compositional induction on their structures. Views that we have a "language of thought," and must have such to be thinkers, are usually committed to this (and much more besides).

Psychological and semantic sententialism are independent doctrines. We could classify unstructured states with structured labels like sentences (semantic but not psychological sententialism). It is *a priori* possible that representing a state of affairs requires representing its constituents in a sentence-like way, though the point of attitude ascription is merely to report on how a person partitions possibilities (psychological but not semantic sententialism).

One line of argument for psychological sententialism claims that our best cognitive models of attitudes are ones on which they are computational states operating on sentence-like objects with properties (a) and (b).[37] Some have suggested that the "productivity" of the attitudes requires psychological sententialism: she who can entertain the thought that something bothered John, and can have the desire that Mary touch nothing, must also be able to entertain the thought that John touched something and be able to desire that Mary bother nothing. This is explained if the states are realized by a system of states with something like natural-language syntax and semantics; it is not so easy to see what other explanation there might be.

That the best models of attitudes are sentential is quite controversial.[38] Even without appeal to contentious psychological models, we should be leery of the above arguments. Attitudes involved in higher cognitive processes in humans are plausibly thought to be sentential for reasons given by these arguments. But one may wonder whether all belief (-like) states of monkeys (which are motivational, involve considerable discriminatory ability, but need not contribute much to something like an ability to reason) are well modeled by sententialist models.[39] Neither do such states obviously have the sort of "compositional complexity" alluded to above.

Opponents of psychological sententialism claim it is false to our conception of the attitudes, a conception of them as states with a certain functional role (usually a role captured by colloquial, or folk, psychology) and which have representational content. For it is perfectly possible to have representational content without being sententially structured; representational properties, for example, might be assimilated to one or another causal relational property. In my opinion, this argument ignores important aspects of our concepts of the attitudes. Attitudes *are* states with certain kinds of motivational roles and representational content; but an attitude is required to have a certain *kind* of representational content. An attitude represents a state of affairs – a congeries of individuals, properties, and relations – *by* representing its constituent individuals, properties, and relations.

Evidence that we think of attitudes as being realized by *structured* representations is given (a) by the naturalness with which we accede to the idea that, for example, having the belief that Bush lost to Clinton requires having a representation of Bush and one of Clinton; and (b) by the problems with accounts of attitude ascription which identify the semantic object of belief with an unstructured object like a set of possible worlds. We reject such accounts because we take it as obvious that states of affairs can be necessarily or logically equivalent without beliefs with those states as objects being identical. This means that the states which realize those beliefs must themselves be different. While it doesn't *follow* from this that belief states realize beliefs by being sentence-like representations of a state of affairs, such considerations, along with (a), make psychological sententialism plausible.[40]

Attitudes and Context

We have yet to find a satisfactory account of APAs. This section reviews some recent proposals. While they differ in particulars, they are united by the idea that attitude ascription involves some sort of *context sensitivity*, and that it is by appeal to this that we should explain hyperintensionality.

Kripke (1979) recounts the sad story of Pierre, who was raised in Paris but taken under dark circumstances to London. As a child, Pierre read (in French) of the city Londres, and accepted as true the French *Londres est jolie*, presumably expressing a belief therewith. He still accepts this sentence. Pierre learned English directly in London; it never occurred to him that he was in the city he called *Londres*. Finding his circumstances mean, he assents to 'London isn't pretty,' and presumably expresses a belief with it.

Kripke poses a puzzle about belief with the case. He observes that we seem committed to a disquotational principle about belief, something like *If a normal English speaker, on reflection, sincerely assents to 'p,' then he believes that p*. If this is true, its analogues in other natural languages are truths, too. We seem committed to the view that translations of truths express truths. The first principle, and the facts, commit us to saying that Pierre believes that London is not pretty. An analogue of the first principle, and the facts, commits us to the truth in French of *Pierre croit que Londres est jolie*. The translation principle, then, commits us to saying that Pierre believes that London is pretty. But, as Kripke observes, Pierre may be supposed to be fully rational, a man committed to consistency at all costs, and so on. So he presumably does not have contradictory beliefs.

Kripke seems to think that there must be a univocal, "context-free" answer to the question, Does Pierre or does he not believe that London is pretty? If we suppose that this is so, Kripke's case is indeed puzzling. For when we concentrate on Pierre's "French thoughts," it seems obvious that we should say that Pierre thinks that the city is pretty, and that he does not think that it is not pretty; when we consider his English thoughts, it is evident that he thinks that it is not pretty.

Perhaps Kripke's case is not so much a puzzle as a dramatic demonstration that ascriptions of propositional attitudes are contextually sensitive; perhaps the truth of 'Pierre thinks that London is pretty' depends in part on how things are with Pierre *and* in part on how things are in the context in which the sentence is used. A number of recent accounts of attitude ascriptions see claims about the attitudes as contextually sensitive. *Sentential-role* accounts take a use of

(P) Pierre believes that London is pretty

to be true just in case Pierre has a belief similar, in some contextually salient role, to that the user would normally voice with 'London is pretty.' *Translational* accounts see (P) as true, provided the complement clause (or what it names) provides an adequate translation of one of Pierre's thoughts; since what counts as an acceptable translation may vary from context to context, (P) may vary in truth across contexts. *Implicit reference* accounts see uses of sentences like (P) as involving a tacit reference by the speaker to a way of thinking, a mental particular (a particular representation or word in the language of thought), or a property of such. Since different speakers may refer to different ways of thinking or representations, uses of (P) may differ in truth.[41]

In Stephen Stich's version of the sentential-role story, belief states can resemble each other in terms of reference, functional role, and ideology, with ideological resemblance determined by the referential and functional similarities of the "networks" in which the states are embedded. Various similarity measures match such states along these dimensions; contextual differences in interest and emphasis select among these measures. Thus (P)'s truth-conditions shift, as do its users' attention and interest. Functional role and ideological setting might be seen as aspects of Fregean sense; Russellian propositions are a little like reifications of referential roles. So this view is a *bit* like the view that attitude ascriptions may relate one to either a Fregean sense or a Russellian proposition.

This approach makes our general success in explaining behavior by ascribing attitudes hard to explain. Presumably it is a belief's functional role that is most relevant in behavior explanation, and so similarity of such roles looms large in behavior explanation. But our behavior explanations are failures if they don't respect the referential properties of others' beliefs. Suppose we disagree about what's best for colds: you think pseudoepherine, I think oxymetazoline. Neither of us has much of a theory about his medication beyond thinking the stuff is the best for colds. 'I shall get some oxymetazoline' has for me the functional role that 'I shall get some pseudoepherine' has for you. Suppose that you are going to the store for pseudoepherine, Mary asks why you're leaving, and I say 'he wants to get some oxymetazoline.' If only similarity in functional role is relevant, this is true on Stich's account. But it's not true.

One response would say that referential similarity is always required in belief ascription, and, additionally, functional similarity is required in behavior explanation. But then I just *can't* explain your behavior to Mary, because nothing in my repertoire matches your motivation in reference and functional roles. But if I say 'he wants to get some pseudoepherine,' I explain your behavior quite well. If we say that *only* referential similarity is required in behavior explanation, the Russellian's problems with this topic recur.

Translational accounts of (P) take it as true when its complement provides a contextually adequate translation of one of Pierre's thoughts or something realizing them. The author's version of such an account begins by assuming that some (weak) version of psychological sententialism is correct.[42] Thus, each of Pierre's beliefs is realized by a sentence-like mental state whose parts, in context, determine a Russellian content. Call what results from pairing the parts of a "sentence" realizing a belief with their contextually determined referents a *thought*. Pretend for now that beliefs are realized by natural-language sentence tokens (which we think of as ordered sets). Then among Pierre's thoughts are

<<'est jolie,' the property of being pretty>, <'Londres,' London>>

and

<<'not,' the negation function>, < <'is pretty,' being pretty>, <'London,' London>>>.[43]

Call the pairings in thoughts of representations with what they represent *annotations*.

Thoughts are pairings of (the parts of) representations with what they represent. The complements of attitude ascriptions also determine such pairings. For example, the complement of (P) provides us with

<<'is pretty,' being pretty>, <'London,' London>>.

Call the pairings named by complement clauses *articulated propositions*, or a-propositions.[44] In ascribing an attitude, we offer the a-proposition our complement determines as a representation or translation of one of the believer's thoughts; the ascription is true provided that the proffered a-proposition is an acceptable translation of such a thought, according to currently prevailing standards.

What is translation, and how might the standards governing it shift across contexts? Translation preserves Russellian content.[45] So an a-proposition p translates a thought q only if p and q, when stripped of the words or representations within them, determine the same Russellian proposition.[46] What else is required in translation? This varies with interests, mutual knowledge, and conversational background. For instance, it may be common knowledge that some of Pierre's beliefs are realized *en français*, and are the focus of discussion. If so, one may expect a restriction on how to translate Pierre's thoughts along the lines of

> In discussing Pierre, 'London' can be used only to represent representations which Pierre voices with 'Londres.'[47]

With such a restriction in place, (P) will be true while

> (P1) Pierre believes that London is not pretty

will not. Other contexts provide restrictions which make (P1) true and (P) false.[48]

Call the sort of restriction just discussed – that in an ascription of attitude to x, an expression can only represent a representation of x's with a particular property P – a *restriction on translation*. Context contributes a collection of restrictions on translation. An ascription *A believes that S* is true in context c provided A has a thought q which can be translated (consistent with all c's restrictions) using the a-proposition that S.

This account attempts to preserve the virtues of direct-reference accounts – their compatibility with "the new theory of reference," their eschewal of "ways of thinking" as meanings or semantic values of expressions – with the idea that in ascribing an attitude we are *somehow* speaking of ways of thinking. It does this by holding that the words in a complement clause have two functions. One is to secure a Russellian referent: In (P), 'London' secures London. The other role is to stand as proxy for the representations of others: 'London' in a use of (P) is a proxy for a way of representing London.[49]

It is possible to get some of the effect of this account without requiring such yeoman service of the words in a belief ascription if we suppose that in using (P) we "tacitly refer" to Pierre's representations, but not via some expression in (P). Tacit reference is not unheard of; John Perry's example is the apparent reference to a location in uses of 'it's snowing.'[50] If (P) involves tacit reference to Pierre's representations, then the semantic value of the predicate

> (P3) believes that London is pretty

on a true use of (P) might be something like the property

> S_1: believing the Russellian proposition that London is pretty under the representation FR

where FR names Pierre's "French representation" of London's pulchritude. Since different uses of (P) may involve different references, simultaneous use of (P) may differ in truth-value.

So say Perry and Mark Crimmins. They hold that sometimes we refer to particular representations, sometimes to their properties. On some uses of (P), the semantic value of (P3) might turn out to be not S_1 but

> S_2: believing the Russellian proposition that London is pretty under a representation that includes a representation with property P*: being typically expressed by Pierre in French.

If there is reference to representations or their properties in belief ascription, then there will be reference to aspects of propositional structure and to how representations "fill" these. This is necessary to differentiate between believing that Hesperus rose before Phosphorus and believing that Phosphorus rose before Hesperus; it's only by saying which representation is responsible for filling which position (*role*, in Crimmins and Perry's parlance) that the difference between the two beliefs can be explained. A full-blown account of a use of (P) involving reference to P* has it making a claim something like this:

> There are representations r and k such that: Pierre believes the proposition that London is pretty under r, k is a part of r, and k, which has P*, is responsible for London filling role u

where role u is the "subject role" of the proposition that London is pretty.

Both the translational and the referential account, in effect, see attitudes as complex relations between an individual, a representation, and a representational content, with the latter being something like a Russellian proposition. Each sees attitude ascriptions as involving some hidden logical structure – quantification over ways of translating in the case of the translational account; reference to representations or properties thereof in the case of the referential account.

In my opinion, the implicit-reference account does not give an acceptable account of the logical properties of attitude ascriptions. Since the representations implicitly referred to may shift from premise to conclusion, the account must say that the argument 'Smith thinks snow is white, so Smith thinks snow is white' is not valid. Worse yet, my use of 'Smith thinks snow is white' may be false not because Smith fails to believe the proposition that snow is white, but because he does not believe it under the representation I refer to. Thus there are contexts in which 'Jones believes that snow is white' and 'Smith believes whatever Jones does' are true (taking the latter to be regimented 'For all p: if Jones believes p under some r, then Smith believes p under some r'), but 'Smith believes that snow is white' is false.

On the translational account, x satisfies *believes that London is large* just if 'London is large' adequately translates one of x's thoughts. Though the standards of adequacy in translation may vary from context to context, these standards are "built in" to the semantic value of the attitude-verb in a context. The verb's context-independent meaning is a rule which takes a collection of restrictions on translation, and returns a rule which pairs off individuals with the a-propositions which translate one of their thoughts. Because of the predicate's univocality in context, the arguments just discussed are valid on a translational account.

Such objections may not be decisive; one might hold that our intuitions about validity are no more infallible than those about truth-conditions.[51] I do believe that the translational or referential account gives the essentials of a correct account of attitude ascription.[52]

Alternatives to Relational Accounts

Alternatives to relational accounts of attitude ascription have recently appeared. We discuss the two most significant.

Relationism

In thought and talk we may represent an object multiple times, as when I think that Twain is Twain or when Mary assertively utters 'Twain isn't Clemens.' Several philosophers have suggested that such representational repetition is relevant to the individuation of meaning and content; Kit Fine has offered a sophisticated account of what he calls semantic relationism.[53]

According to Fine, uses of phrases stand in a relation of *coordination*, which is "the very strongest relation of synonymy" (Fine, 2007, p. 5). In a normal use of 'Twain is Twain' the uses of 'Twain' are coordinated with one another; in a normal use of 'Twain is Clemens' the uses of the terms are not coordinated. To understand use of the first sentence one must recognize the coordination; this signals a difference in meaning and proposition expressed. Similar things are true of uses of multiple sentences and multiple thoughts (even when the token uses or thoughts originate with different agents).

Fine thinks that the notion of coordination "can do much of the work of sense," even though (to take an example) on Fine's view there is no difference in proposition expressed by 'Twain is an author' and 'Clemens is an author' (Fine, 2007, p. 5). Fine is a referentialist and so in this case (where coordination doesn't enter the picture) sees no meaning-relevant difference. Fine posits an ambiguity (different "readings") of sentences like 'Ted said that Twain is an author.' On one reading, a use of the sentence is true iff Ted assertively uttered a sentence that expresses the proposition that Twain is an author *and* in so doing used a name of Twain that is coordinated with the ascriber's use of 'Twain.' Thus there is an understanding of 'Ted said that Twain is an author' on which its truth doesn't require the truth of 'Ted said that Clemens is an author.'

Whatever the virtues of the idea that content is relational, it's not clear that coordination can explain our practices of attitude ascription. Consider the following example: Eleanor Jane (=EJ) is Jane to her friends, Eleanor to others; her friends are well aware of this. You and I are her friends. I see that Bob and Ray, who know EJ but are not her friends, see her leave; I see that only Ray realized that it was EJ. (Of course, what Ray thinks is 'there goes Eleanor.') I say to you "Bob and Ray saw Jane leave, but only Ray knew/realized that it was Jane who left." This is a perfectly natural way to convey something along the lines of: Ray has some knowledge expressed by *a just left*, *a* a good answer for Ray to *Who's that?*; Bob has no such knowledge. An explanation of this in terms of coordination (as opposed, say, to one in terms of the translational account discussed above) presumably must invoke coordination between my use of 'Jane' and either some perceptual representation of Ray's of EJ or one of his tokens of 'Eleanor.' But the relation between my use of 'Jane' and Ray's representations doesn't seem to be anything at all like the relation Fine has in mind when he says, of coordination across people, that

> Perhaps a paradigm case is when I derive my use of a name from someone else…. there are many other cases … suppose … an object in common view and that we communicate about it by means of the pronoun 'it.' The various uses of the pronouns are coordinated and someone who did not know that they were being used to refer to the same object, even if he knew that each of them referred to that object, would have failed to understand what was said. (Fine, 2007, p. 86)

Someone might hear Ray say 'that's Eleanor leaving' and understand Ray, hear me say 'Ray knows that Jane left' and understand me while not knowing that Ray's 'Eleanor' co-refers with my 'Jane.' Someone who 'associates two routes' to EJ with the two terms might be like this.[54]

'Descriptivism'

Some separate the idea that belief is a relation to a proposition (or some other "belief object") from the idea that to ascribe belief is to say, of a person and a belief object, that the first is related to the second. Instead of using 'that Twain was an author' to *refer* to an object of belief, perhaps we use it to *describe* a belief object. Kent Bach, for example, proposes that a sentence of the form *x believes that S* is true iff that there is a proposition that x believes that has a property determined by *that S*. On this view, though the clausal complement in *x believes that S* expresses a proposition p, the role of this proposition is only to help determine a property P; the ascription is true only if some belief object of x possesses P.[55] What property the sentence ascribes varies with its use; phrases like 'believes that Twain is sad' are "semantically incomplete," and determine a property only when provided with contextual supplementation.

A motivation for this view is that it explains such things as why substitution of 'Clemens' for 'Twain' in the complement of an attitude ascription can change truth-value: uses of different complement clauses may determine different properties even if the clauses taken in isolation determine the same proposition.[56] It is not clear whether this view makes different predictions about the truth- or felicity conditions of uses of attitude ascriptions than does the translational view discussed at the end of the last section, particularly given that one way to specify a "translation manual" is in terms of properties of the representations that realize someone's attitudes.[57]

A variant descriptional view is given by Friederike Moltmann. Like Bach, Moltmann holds that in attitude ascription the clausal complement helps to pick out a property of the object of an attitude; unlike Bach, Moltmann takes the objects of the attitudes to be "products" of cognitive acts of judging, asserting, wishing, and so forth.[58]

Appendix: *De Dicto*, *De Re*, and *De Se*

It is common to distinguish between *de dicto* and *de re* attitude and attitude ascriptions. Those who do so may have any of a number of distinctions in mind. The most straightforward distinction is a syntactic one exhibited by

(la) John believes that Ned is tall.
(lb) John believes of Ned that he is tall.

and

(2a) John believes that Ned is tall.
(2b) There's some x such that x is Ned and John believes that x is tall.

In the b-sentences, the clause governed by 'believes' contains (elements like) variables which are bound from without. These are *de re* ascriptions. *De dicto* ascriptions, like the a-sentences, are ones in which the content sentence (the sentence which 'that' introduces) contains no variables bound from the outside.[59]

The terminology arises thus: *De dicto* ascriptions report that the believer has what a sentence says – a *dictum*, or proposition – as the object of an attitude. *De re* ascriptions relate the believer to a thing (or *res*) – Ned, in our examples – specified independently of how the believer conceptualizes it. Note that from (1b) and 'Ned is Ed' we can infer 'John believes of Ed that he is tall,' while (la) and the identity do not seem to imply 'John believes that Ed is tall.'

Say that when ascriptions are related as are

(3a) x believes that t is F
(3b) x believes of t that it is F

with 'it' in (3b) referring back to t, b is the *de re* ascription corresponding to a. Since arbitrary (positive) noun phrases can occur in the position of *t,* a *de dicto* ascription and the corresponding *de re* ascription are often independent. That you believe that some dogs have fleas neither implies nor is implied by the claim that you believe of some dogs that they have fleas. (You may have the first belief without the ability or willingness to identify or describe any particular thing as having fleas; you may identify Rex the dog as something beflead, but think him a skunk and that only skunks have fleas, thereby having the second belief but not the first.) Likewise, that you wish that the winner of the lottery be heavily taxed apparently neither implies nor is implied by the claim that you wish, with respect to the winner of the lottery, that he be heavily taxed.[60]

Limiting attention to cases in which *t* is replaced with something other than a quantifier – a demonstrative, indexical, or proper name – it is plausible that a *de dicto* ascription implies the corresponding *de re* ascription, for it is plausible that (for example) (lb) follows from (la).[61] Only the Millian holds that implication goes in the other direction.

Some accounts of attitudes make some attitudes dependent on objects external to the believer. A Russellian who takes Odile to be a part of the proposition that Odile said hello will usually hold that it's impossible to believe that Odile said hello if she does not exist.[62] The *de re* senses which some Fregeans introduce cannot exist unless what they (in fact) present exists. To have such a sense as a belief object is to have a belief which depends upon a particular object. A second use of the term *de re attitude* applies it to states which are object-dependent in this way – an attitude towards something (a Russellian proposition, *de re* sense, whatever) which is itself ontologically dependent upon an object which the belief is about.

This use of the terminology is different from the first. Sentence (la) reports a *de re* attitude on a Millian or Evansean view, since on these views the proposition that Ned is tall cannot exist unless Ned does. But sentence (la) is not a *de re* ascription.

A third use of the terminology arises as a result of the view that some belief involves an epistemically significant relation to an object. Russell held that if a proposition contained an object as a constituent, one couldn't believe the proposition unless one were *acquainted* with that object; acquaintance, in turn, could only be had with objects about which one, in some important sense, could not be deluded (see Russell, 1911; 1912). Even though no one now accepts quite so stringent a requirement, it is commonly thought that object-dependent propositions can be believed only by those with some fairly significant epistemic contact with their constituents.[63] Many writers use '*de re* belief' in such a way that *de re* belief is a kind of belief whose possession requires having one or another epistemically interesting rapport with the object or objects the belief is about.

Does having an object-dependent belief (*de re* in the second sense) require having intimate epistemic contact with the relevant objects (*de re* in the third)? I would say not, as anyone who understands a sentence with a proper name of me may have object-dependent beliefs about me, but such a person need have no particularly interesting epistemic relation to me. An objection runs thus: On your view, someone without such contact with an object x – say, someone one who can (only) describe x – can come to have object-dependent beliefs about it just by "christening" x with a name stipulated to always "introduce" x into the belief it expresses. This implies that someone with only descriptive knowledge of x can be in exactly the same epistemic relation to x as someone who has object-dependent knowledge of x. But this is absurd, since someone who has object-dependent knowledge knows something that someone with only descriptive knowledge doesn't.

This argument succeeds only if it is allowed that introducing a name for an object does not change epistemic relations to the object. But introducing a name (when one previously had none) does create a new epistemic link with the nominata: after the christening, one has a means to *refer* to the object, and express propositions in which the object occurs, while before one did not. Of course, the sort of link a christening opens to the object can't be exploited to gain "interesting extensions" of one's knowledge in the way that other epistemic links (perception, introspection, relations established via third-party testimony) can be. But that doesn't mean that the link doesn't exist, as the argument must assume in order to go through.

There is apparently a difference between what is typically reported by

(4a) John believes that he himself is tall

and

(4b) John believes that John [or: that man] is tall,

even if 'John' (or 'that man') refers to John himself. If John doesn't realize that he is John (or that man) – because of amnesia or some other circumstance – the a- and b-sentences might diverge in truth-value. For if John is suffering from amnesia, he can think (to himself) *I am tall*, while thinking *But John (that man) is not tall*. Assuming that inferences like that from (1a) to (1b) are valid, this argument also shows that what's reported by (4a) isn't (merely) a *de re* belief, either. The difference is even more pronounced with attitude verbs that take infinitival complements. Witness the difference between

(5a) Hazel expected to meet me for lunch

and

(5b) Hazel expected that Hazel would meet me for lunch.

The term *attitude de se* is often used to refer to the sort of belief about oneself typically reported in English using the 'she herself' locution or by attitude verbs with an infinitival complement.[64]

What, exactly, is (4a) telling us about John? According to Frege, "everyone is presented to himself in a particular and primitive way, in which he is presented to no-one else" (Frege, 1977). In saying this, Frege had in mind a "distinctively first-person" way of thinking of

oneself, which typically accompanies one's 'I'-thoughts.[65] One view is that a *de se* ascription to x ascribes to x a thought which involves x's private mode of self-thought.[66]

One way to avoid private thought-objects in an account of thought *de se* treats 'he himself' (and analogous uses of simpler pronouns like 'he') as functioning somewhat as predicate abstractors, so that the logical form of (4a) is suggested by

(4c) John believes λx(x is tall)

One then says that *de se* belief involves a distinctive way of ascribing a property (self-ascribing it). All believers can self-ascribe properties, and all properties are (in principle) open to self-ascription. But of course only you can *self*-ascribe being tall to yourself.

As noted above, David Lewis takes this line, and holds that *all* attitudes are relations to properties; what appears to be "purely propositional belief" (such as the belief that 2 + 5 = 4) is self-ascription of "propositional properties" (being such that 2 + 5 = 4). Lewis argues that this provides a superior account of belief, using examples like that of the propositionally omniscient gods, Gary and Ed. Those working in a possible-worlds framework often adopt a variant of Lewis's account, on which the objects of attitudes are sets of "centered worlds," where a centered world is a triple <w, u, t>, w a possible world, u an object in w, and t a time; what self-ascribing (say) the property of being sad comes to, if one adopts this framework, can be identified with having {<w,u,t> | at t in w u is sad} as an object of belief.[67]

Lewis's and kindred examples raise a number of questions. Are *de se* attitudes a distinctive sort of attitude that cannot be identified with or somehow reduced to *de re* and/or *de dicto* attitudes? Are there forms of attitude ascription (or distinctive understandings of some such forms) in natural language that are distinctively *de se* and which convey information that is not conveyed by *de re* and/or *de dicto* attitude ascriptions? If the answer to either of these is affirmative, does an account of *de se* attitudes or *de se* ascriptions require us to introduce a new sort of content? It has been argued that examples like Lewis's give us no good reason to think that the answer to the first two questions is affirmative.[68] But even assuming that we think that there are distinctively *de se* attitudes and ascriptions, it is not clear that that is reason to think that content is not propositional in some central sense. Fregeans argue that they can accommodate the *de se* in terms of special modes of presentation.[69] A translational account of attitude ascriptions can allow that for any sentence S which is free of the 'he himself' locution (or cognates), if S is true, then 'Ed knows that S' is true in the two-gods story. This seems to get at what Lewis has in mind in describing the case as one in which Ed is propositionally omniscient.[70] And it is consistent with the falsity of 'Ed knows that he himself is Ed,' if 'he himself' is so restricted that in ascriptions to Ed it can only represent 'I' or other "first-person" modes of reference. Other views of the nature of content can accommodate Ed and Gary's ignorance in other ways.[71]

Notes

1 The caveat 'normally' allows us to hold that one might believe, say, that Zeus was a god, though the belief would be without truth-conditions due to a reference failure of 'Zeus' or a corresponding part of the representation realizing the belief. It is unclear that we can avoid such a rider, since there need not be only finitely many ways in which a representation might fail to have truth-conditions. The parenthetical 'or the like' allows, for instance, that attitudes like desire and wishing may have objects with satisfaction, not truth-, conditions.

2 Chomsky (1965; 1986) holds that we know the grammar of our language, though the knowledge is not conscious or inferentially integrated with conscious knowledge. Stich (1978) criticizes him on these points. Fodor (1975) exuberantly postulates propositional attitudes without regard to conscious access or cognitive integration; Searle (1990) holds that representation without the possibility of conscious access is impossible.

3 See, for instance, Higginbotham (1983), which presents an alternative to accounts in Barwise (1981) and Barwise and Perry (1983). Barwise and Perry take seeing a lion dance to be a relation between a "scene" and a perceiver, but (in 1983) assimilate the objects of the attitudes to the objects of perception. Neale (1988) discusses Higginbotham's account.

Martin (1992) argues that visual perception may involve representation without (so to speak) the kind of conceptualization required for a propositional attitude, as when I see an object without immediately registering its presence or properties.

4 Attitude verbs presumably pick out relations between individuals, propositions, and times; strictly, attitudes themselves are such relations. For simplicity, tense and time are ignored throughout.

5 There are important differences between assigning semantic properties to expression types in a context and assigning them to expression tokens or their utterance. Most of the sequel slurs this distinction. And I generally suppress reference to the fact that expressions are sensibly assigned semantic values only relative to a context of use.

Frege, Russell, and many of their heirs seem to have assumed that sentence uses express at most one proposition. Many contemporary theorists have abandoned this idea (see, for example, Cappelen and Lepore, 2005), though those of a Gricean bent will say that one of these – what is strictly and literally said – is distinguished via its relation to a sentence's meaning.

Many now say that typically a sentence's meaning does not determine a proposition-cum-object-that-determines-truth-conditions, but something – a propositional schema, or propositional skeleton – that requires supplementation before truth-conditions can be determined. (A standard example is a sentence like 'My book is interesting': the possessive is not ambiguous, but it can express many relations (here, for example, authorship and possession).) For discussion see Cappelen and Lepore (2005), Bach (1994), and Soames (2002). Those who hold such views will hold at best a qualified version of what is below called 'the relational account.' It would take us too far afield here to discuss this variant view in detail.

6 Italicization is used as a device for talking about expressions. (Precisely: It functions as a method of quasi-quotation, in Quine's sense.) Single quotes are used to mention expressions.

7 This line of thought can be found in Salmon (1986) and Soames (1987).

8 See Higginbotham (1992), Soames (1992) for discussion.

9 Davidson (1967). Some identify the task of a theory of meaning with giving an account of truth-conditions, which they in turn identify with assigning sets of worlds or situations to the sentences, which are in turn identified with what sentences say. See, for example, Montague (1974).

10 Hyperintensionality is distinct from what Quine calls *opacity*. As Quine defines the notion, a linguistic context $e(\ldots)$ is opaque provided there are singular terms t and t' such that $t = t'$ is true, but $e(t)$ and $e(t')$ have different extensions. The opacity of 'believes that… won' follows from the assumptions that definite descriptions are terms, and that 'the lottery winner = the man in the corner,' 'Jo thinks that the lottery winner won,' and 'Jo doesn't think that the man in the corner won' are all true. That 'believes that… won' is hyperintensional does not follow from this. Conversely, the hyperintensionality of 'believes that this is…' can be demonstrated by means of a suitable pair of necessarily equivalent predicates, but its opacity can't.

11 Precisely: Transformations which are valid within the scope of modal operators fail within the scope of attitude verbs.

12 See Mates (1950) and Burge (1978); compare Yagisawa (1984).

13 For Soames's view see Soames (2010b), for King's, King (1997). These and related views are critically discussed in a collection edited by Hunter and Rattan (2013).

14 Of course those who say this need to explain how it can be that, for example, it's necessary that the proposition that 7 is prime is true – and thus would be true even if there were no things to represent. For one account of this see Richard (2013a; 2013c).

15 The question of whether propositions can change truth-value over time is the subject of Brogaard (2012); some reasons to doubt Brogaard's view can be found in the first part of Richard (2015). Discussion of the sort of relativism suggested by (c) can be found in Capellen and Hawthorne (2010), MacFarlane (2014), and Richard (2011).

16 On propositions as sets of worlds, see Stalnaker (1984; 1987; 1999), Powers (1978), Richard (1990), and Cresswell (1985). Soames (1984; 1987) objects to situation semantics' account of propositions; some of his points are anticipated in Richard (1983). Stalnaker (1984) and (1999) give several arguments for the view that the objects of belief should not be individuated more finely than sets of worlds. Some of these arguments are critically discussed in Richard (2013b). An alternative account identifies propositions with collections of possible and impossible worlds (or situations). See Soames (1987) for criticism and Edelberg (1994) for a defense.

17 See the essays in Stalnaker (1999). An elaborate defense of this sort of idea is found in the work of David Chalmers; see, for example, Chalmers (2002).

18 See Richard (2013b, ch. 9), where this sort of point is made about a view Graeme Forbes once held. Forbes presses this kind of objection against views of David Chalmers in Forbes (2011).

19 Lewis (1972) and Cresswell (1985) are possible-worlds semanticists using structured propositions. Salmon (1986) and Soames (1987; 1989) adopt a Russellian view on which the structure of the proposition that S generally recapitulates that of S itself. Of course, many linguistic views of propositions identify propositions with structured (linguistic or quasi-linguistic) items; among the many examples are Segal (1989), Richard (1990), and Larson and Ludlow (1993).

20 Given the almost universally accepted claim that names rigidly designate their bearers; for discussion see Chapter 36, NAMES AND RIGID DESIGNATION, and Chapter 35, REFERENCE AND NECESSITY.

21 A little more precisely, the arguments made it plausible that such terms are rigid designators of their bearers, and thus the modal properties of the propositions expressed by *A(t)* and *A(t′)* are identical if t and t′ name the same thing and the dotted position in *A(…)* does not occur in the scope of a device of quotation or attitude verb. See Kripke (1972), Kaplan (1977), Donnellan (1972; 1974), and Putnam (1975a).

22 In this argument, 'object of belief' should be understood as shorthand for 'what's named by the complement clause in a belief ascription.'

23 But see Crimmins (1992) for discussion of this line of argument.

24 This argument is in Richard (1983). Soames (1987) suggests that it generalizes to show that co-referential proper names are intersubstitutable in APAs. Forbes (1987), Richard (1990), and Crimmins (1992) offer various suggestions as to why the argument does not establish a direct-reference view.

25 Such views owe a great deal to Grice (1990) and Kripke (1977). Versions are in Richard (1983; 1987); Soames (1984; 1987); Salmon (1986); and Berg (1988).

26 Richard (1987) tries to square folk psychology with the direct-reference view. Richard (1990) and Crimmins (1992) argue that the view's inability to account for the literal truth of folk psychology is a serious flaw.

27 Graeme Forbes (1989) has suggested that sense determines actual reference, and that contexts like necessarily … are extensional, the extension of a sentence being a state of affairs. He then adopts an account of sense like that of Evans discussed below. Richard (1993a) and Crimmins (1993) discuss Forbes's account.

28 See Richard (1988; 1990). One hears the response that (a) I cannot understand the other unless I know that she uses 'Frege' to refer to Frege, but (b) I cannot know this unless there is some similarity in the way the other and I think of Frege. But (b) is wrong. For example, I might know on the basis of third-party testimony that you use 'Frege' for Frege; or I might know that you are an

American and in situation F, and that Americans in situation F use 'Frege' for Frege. It is also unclear why I *must* understand the other in order to correctly ascribe a belief to her.

29 See Evans (1982) and Forbes (1989). The idea arguably originates in Kaplan (1969).

30 See Evans (1982) and McDowell (1984). Such views, of course, seem heir to the problems about the idiosyncrasy of sense mentioned above.

31 For discussion, see Evans (1982), Segal (1989), and Recanati (2013).

32 See Higginbotham (1986) and Hand (1991). Hand also observes that for many cases involving negative polarity and infinitives, positing (the utterance of) a discrete sentence with the content of the ascribed attitude is implausible.

33 Intensional isomorphism (and relations like translation) are not dyadic but actually quadratic relations between two sentences and two languages.

34 Admittedly, Carnap himself did not seem to take it in this way.

35 See Richard (1990). A different response is given in Leeds (1979).

36 See Schiffer (1987) for an inventory. Richard (1995a) attempts to meet serious objections to sententialism in a way that would be acceptable to those with broadly nominalistic inclinations.

37 Perhaps the most influential arguments are in Fodor (1975; 1987); those mentioned in the text are suggested by him. A sampling of the literature is in Block (1981) and Rosenthal (1991).

38 McLaughlin (1993) gives an introduction to current debate.

39 A summary of some relevant observation and experiment is Cheney and Seyfarth (1990).

40 For discussion see Stalnaker (1984), Dennett (1987), Richard (1990), and Crimmins (1992).

41 Stich (1983) and Boer and Lycan (1986) present sentential role accounts. The latter is discussed in Richard (1990). Richard (1989; 1990; 1993a; 1993b) develops a translation account. Grandy (1986) offers an earlier translational account. Schiffer (1979) suggests an implicit reference account, in which tacit reference is (apparently) made to intersubjectively accessible ways of thinking of objects and properties. Perry and Crimmins (1989) and Crimmins (1992) develop the version discussed below. Richard (2013b, ch. 14) contains a lengthy discussion of Kripke's puzzle.

42 See Richard (1989; 1990; 1993b).

43 Here the quotation names should be thought of as names of particular token representations of Pierre's which are instances of the quoted types.

44 Called *Russellian Annotated Matrices* in Richard 1990. Note that in describing a-propositions, quote names name expression types.

45 It would be possible to deny this and still preserve something of the spirit of the account suggested here. One might say that the normal or default mode of translation is one which preserves Russellian content. One would go on to suggest that just as the intentions of speakers might require a use of 'London is pretty' in 'Pierre thinks London is pretty' to represent one of Pierre's 'French thoughts,' so might these require a use of 'this is a very pleasant place' to represent a thought expressed by 'hier ist es sehr gemütlich,' though the Russellian content of 'gemütlich' and 'pleasant' in their respective languages are not identical.

Two developments suggest themselves. The less radical simply allows that in context, correlations (the functions which map parts of a-propositions to parts of thoughts) may occasionally map (e, x) to (f, y) when x is not y. More radically, the atomistic account of translation used in the text would be replaced by a more holistic one, in which correlations are replaced by functions which map whole a-propositions to whole thoughts.

46 Slightly more precisely: Translation requires that there be a *correlation* function f which maps the annotations in a-propositions to annotations in thoughts such that q can be obtained from p by replacing p's parts with their image under f. The text suppresses complications arising with iteration of attitude verbs. See Richard (1990).

47 Strictly speaking, a restriction on translation tells one that an annotation (such as the pair <'London,' London> can only be used to represent certain kinds of annotations (e.g., those of the form <'Londres,' London>. For details see Richard (1990; 2013b).

48 The restriction in the text is really on the use of the annotation <'London,' London>. A more detailed account of the nature of contextual restrictions is in Richard (1993c). There it is proposed that context associates a (possibly null) "theory" about how a representation functions in thought with each pair of an individual u and expression e; the contextual restriction on a use of e in an ascription of attitude to u is that e can be used to represent only a representation r of u's such that the theory associated with u and e is substantially correct when taken as a theory about r.

49 Soames (2002) gives useful criticisms of the view just sketched. A response to Soames is given in Richard (2013b, ch. 13).

50 See Perry (1986). Perry and Crimmins (1989), and Crimmins (1992) give the account sketched below.

51 For critical discussion of translational and implicit reference accounts, see Crimmins (1992), Richard (1993b; 1995b), Saul (1993), Schiffer (1992), and Soames (1995).

52 Later work by Crimmins (1998) pursues a very different account of attitude ascription, on which it involves pretense. For example, when one says that someone believes that Hesperus is not Phosphorus, one pretends that Hesperus and Phosphorus are different things, so that thinking about Hesperus is not the same thing as thinking about Phosphorus. Crimmins's account exploits ideas of Kendall Walton about pretense and utterance truth in order to assign intuitively correct truth-conditions to attitude ascriptions. It would add too many words to an already too lengthy chapter to discuss Crimmins's imaginative account; Richard (2013b, ch.10) gives a critical discussion.

53 Fine (2007). There is discussion and elaboration of Fine's view in Soames (2010a) and Fine (2010).

The idea that (for example) there is a difference in content between sentences of the forms *S(…t…t…)* and *S(…t…t′)* even when t and t′ are synonymous is not new. Putnam (1954) (reprinted in Salmon and Soames, 1988) suggests something like this; chs 2–4 of Richard (2013b) attempt to develop a view that is in some ways kindred to Fine's.

54 Of course such a person wouldn't know that Ray's utterance is what grounds the truth of my utterance, but that seems neither here nor there so far as Fine's elaboration of the notion of coordination is concerned.

55 Bach (1997). As I understand Bach, P is possessed by q only if q entails p.

56 Bach does not give an account of the logical syntax of attitude ascriptions, so my exposition may make presuppositions not wholly faithful to his intent.

57 Because of space considerations, I do not here take up Michael Devitt's (1995) more elaborate descriptivist view. Unlike Bach, Devitt gives a catalog of the sorts of properties that he takes to be (quasi-)conventionally associated with clausal complements; he also (unlike Bach) attempts to give an explanation of how it could be that the meanings of attitude ascriptions are consistent with the idea that folk-psychological belief/desire generalizations are in some sense lawful. For a critical examination of Devitt's view, see the exchange between Devitt and me in Richard (1997) and Devitt (1997).

58 Moltmann (2014). Like Devitt, Moltmann essays a catalog of the sorts of properties that are ascribed by use of clausal complements. Moltmann adduces some interesting syntactic evidence for the idea that attitude ascriptions are ascriptions of relations to "cognitive products."

59 Slightly more precisely, *de re* ascriptions contain elements (pronouns or variables) which are within the scope of the complementizer for the attitude verb, and which are either bound to a noun phrase outside the complementizer's scope, or have an antecedent outside the complementizer from which they acquire their reference. (This definition may not capture quite the class of ascriptions each author who uses the terminology calls *de re*.)

60 This has been denied by various latitudinarian accounts of *de re* attitudes; see Chisholm (1976) for an example. See Kaplan (1969) and Sleigh (1967) for discussion.

61 I take definite descriptions to be quantifiers.

62 This assumes that it's impossible to have the belief unless the proposition exists, and that it's impossible for a proposition to exist unless its parts do.

63 Much of the discussion of Kripke's examples of contingent *a priori* knowledge seems to be driven by the assumption that object-dependent knowledge requires epistemic rapport. See, for example, Donnellan (1979) and Forbes (1989). See also Kaplan (1969; 1977; 1978; 1989) and Richard (1993a). Jeshion (2010) contains recent work on object-dependent knowledge.

64 Castenada (1966; 1967) first brought out the importance of the divergence between the a- and b- sentences. It has been extensively discussed in the literature; early examples are Perry (1979), Lewis (1979), and Chisholm (1981). Boer and Lycan (1980) deny that there is a difference in the truth-conditions of (4a) and (4b); Boer and Lycan (1986) retract this.

A standard assumption in the linguistics literature is that in sentences like (5a) the complement contains an unvoiced phrase (usually called PRO) in subject position that is controlled by the ascription's subject term. (To a first approximation, control is a relation in which the controlled element inherits its semantic properties from the controller.) It has been suggested that when an attitude verb has its infinitival complement with a PRO subject controlled by the verb's subject, the only interpretation possible is *de se*. For discussion see Chierchia (1990) and Pearson (2012).

65 Why, one might ask, must this way of thinking be private? According to Frege, a way of thinking presents no more than one thing. Presumably Frege assumes that the way of thinking in question would 'seem first-person' to whomever used it – so that if I were to use the mode of thought you use with T to think of x, I would have to do the sort of thing I do when I think to myself *I am tall*. This all seems to imply that if I could use your private mode of self-thought, I could think that you are tall by thinking *I am tall*, which seems absurd.

66 Evans (1981), Peacocke (1981), McGinn (1983), and Forbes (1987) present Fregean accounts of *de se* thought.

67 There are epicycles on this that one might invoke if one works in a Hintikka-style framework. For discussion see Pearson (2012).

68 A recent example is Cappelen and Dever (2014).

69 Evans makes suggestions about how one might do this in Evans (1982); a variant of Evans's approach is discussed in Stanley (2011).

70 This ignores presumable (but irrelevant) limitations of expressive capacity in English.

71 Examples are the discussion in Stalnaker (2008, ch. 3) and that in Perry (1979). Of the later, Lewis (1979) says that he is sure it "works as well" as his own, but that it is "more complicated."

Holism

CHRISTOPHER PEACOCKE

The question must arise whether a doctrine which is attributed to all of Quine, Putnam, Davidson, Rorty, Gadamer, and Heidegger is possibly a doctrine which comes in more than one version. Even the most ardent taxonomist is likely to draw back from classifying the various actual and possible positions which emerge from the very tangled history of recent discussions of holism. I will be approaching the matter by addressing a series of questions, starting with those which are most likely to arise in the mind of those philosophers who regard holism with a mixture of fascination and suspicion.[1]

1 What Is Meaning Holism?

Here is a highly general formulation of global holism about meaning, a formulation acceptable to holists of many different stripes:

> (GH) The meaning of an expression depends constitutively on its relations to all other expressions in the language, where these relations may need to take account of such facts about the use of these other expressions as their relations to the non-linguistic world, to action, and to perception.

This is a constitutive thesis about what it is for an expression to have a certain meaning. It is neither an epistemological thesis, nor a psychological thesis; though of course if it is correct, it will have consequences for both psychology and epistemology. It goes far beyond the less controversial claim that in assessing the evidence that a given expression has a certain meaning, we must take account of the properties of any sentence in which the expression occurs, regardless of what else is in that sentence.

(GH) is non-committal in at least two respects. First, different theorists who are both committed to accepting (GH) may emphasize different relations to the non-linguistic world as partially constitutive of meaning. Some theorists accepting (GH) may give a special status to observable states of affairs; others may not. Empiricism is not written

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

into, nor entailed by, (GH). Second, one who holds (GH) is not committed to saying that one can make explicit, in a non-circular way, the relations to all other expressions in which a given expression must stand if it is to have a given meaning. Interpretationism is the doctrine that in saying what it is for a particular expression to have a given meaning, a fundamental place must be given to the fact that under optimal interpretation of the language in which the expression occurs, the expression is assigned that meaning. According to the interpretationist there may be more to be said about optimal interpretation in general, and more to be said about various particular meanings. But neither of these, according to the interpretationist, will amount to a full account of what it is to grasp a given meaning unless they actually mention optimal interpretation itself. This is not the place for a discussion of the important question of the correctness of interpretationism, and one of its possible motivations, a certain subjectivism about propositional attitudes and contents (as in McDowell, 1986, and possibly Davidson himself). All that matters for present purposes is that it is *prima facie* consistent for a global holist about meaning to be an interpretationist. (For discussion of Davidson's position, see Chapter 13, RADICAL INTERPRETATION.)

Global holists who, unlike interpretationists, believe that grasp of a particular meaning can be made explicit without presupposing the understander's grasp of that meaning, can make use of the notion of an *understanding-condition* in specifying meanings. An understanding-condition is an explicit statement of the condition a person must meet to understand a given expression, a statement which does not at any point take for granted understanding of the expression in question, nor possession of the concept it expresses. We can formulate the global holism of these theorists in:

(GHE) For a thinker to meet the understanding-condition for any expression E, there must exist certain other expressions $E_1, \ldots, E_n$, such that

(a) the understander meets a certain specifiable, non-circular condition $R(E, E_1, \ldots, E_n)$; this condition may concern the use of the expressions $E_1, \ldots, E_n$, and it may concern their relations to the non-linguistic world; and

(b) the expressions E, E_1, …, E_n exhaust the expressions in the understander's language.

Global holism of the sort captured in (GHE) itself comes in several kinds. One kind is that variety which recognizes certain methods of establishing sentences containing a given expression, or certain methods of deriving consequences from them, as canonical. It writes these methods into the relevant understanding-conditions. One example of a global holism with canonical methods, (GHEC), restricted to the language of mathematics, would be the "pure mathematical holism" mentioned by Dummett, which identifies truth with provability by any of the canonical methods acknowledged in classical mathematics (Dummett, 1991, p. 226). Since some sentences can be proved outright by classical methods, we have in this example one of the extreme forms of holism attacked by Dummett, according to which understanding another person's expression sometimes involves knowing which sentences containing it he holds true (Dummett, 1975, appendix). This framework of classification also formally leaves space for a further kind of case, that of a kind of holism which does not accept the designation of any methods as canonical (GHENC). Such, for instance, would be the position of a global holist who thinks that we can usefully speak only of similarity of

meaning, not of identity of meaning, and who holds that two sentences are more similar in meaning the greater the overlap in accepted methods of establishing them.

Those already well acquainted with this territory will recognize that (GHE) is the natural formulation of that kind of global holism when the apparatus of possession conditions, as a means of individuating concepts, is adapted to the case of linguistic meaning (Peacocke, 1992). I have chosen this formulation for its bearing on the issue of the circularity of global holism. Those who reject all forms of global holism, but still accept the possibility of explicit formulations of understanding-conditions, commonly propose that there is a certain non-trivial, partial ordering of all the expressions of a language. This ordering has the property that to elucidate the meaning of an expression at any given place in the ordering, it is not necessary to mention its relations to expressions later in the ordering. Since the global holist will say that there is no such ordering, it is natural to wonder whether a global holist can avoid circularity in his account of meaning. Dummett, for one, characterizes holism as "the doctrine that any meaning-theory is inevitably circular" (1991, p. 241). In fact the availability of the above form (GHE) should indicate that there is no structural obstacle of principle to the global holist's giving non-circular accounts of the understanding of particular expressions. For instance, one form of global holism might state that to understand a certain expression, one must appreciate that sentences containing it can be established by a certain finite family of methods, where a statement of the methods involves all the other concepts expressed in the language. This may not be plausible – it will be discussed below – but provided that the methods can be specified without presuming on any prior understanding of the expression in question, it is not circular. A global holist who possesses such non-circular specifications may rightly insist that he admits and employs the notion of the content of a given individual sentence. For him, that content will be fixed by the meaning specifications for the components of the sentence, together with the way in which they compose the sentence.

Quine is not a holist of any of the sorts so far distinguished, for he has always acknowledged a level of observational vocabulary for which he would say that all of the above theses are false. Quine's holism is captured by the preceding formulations only if we understand the talk of expressions, and variables ranging over them, as restricted to the non-observational part of the language. We are clearly entering here the realm in which holism comes in degrees. A position may be classified as more holistic the fewer restrictions we have to place on the talk of expressions in order for the position to be classified as holistic according to the characterizations above. This matter of degree arises also for conceptual-role theories of meaning, as advocated in Block (1986), Harman (1982), and Sellars (1974), which state that for an expression to have a particular meaning is for it to have a certain role in its user's psychology. A conceptual-role theory of meaning will similarly be more holistic the fewer restrictions it places on those features of an expression's total role which it regards as individuative of the expression's meaning. The limiting case at the end of the spectrum of increasingly holistic alternatives is that in which no restrictions are placed on those features of the conceptual role of an expression which contribute to individuating its meaning. Acceptance of this limiting case is naturally accompanied by skepticism that the strict relation of intersubjective synonymy of expressions – at least for that aspect of meaning captured by holistic conceptual role – is ever, in fact, satisfied (cp. Field, 1977).

I turn now to consider grounds which have been offered in support of meaning holism.

2 Does the Duhem–Quine Thesis Provide a Ground for Meaning Holism?

This question must be split into two parts:

(a) Is the Duhem–Quine Thesis true? (If it is not, it will not be a ground for anything.)
(b) If the Duhem–Quine Thesis is true, does it support meaning holism?

Actually we should distinguish the Duhem thesis from the Quine thesis. Duhem wrote:

> the physicist can never subject an isolated hypothesis to experimental test, but only a whole group of hypotheses; when the experiment is in disagreement with his predictions, what he learns is that at least one of the hypotheses constituting this group is unacceptable and ought to be modified; but the experiment does not designate which one should be changed. (Duhem, 1962, p. 187)

Two points emerge from Duhem's discussion. First, Duhem's thesis is specific to hypotheses of physics. He explicitly contrasted the physicist's situation with that of a physiologist who wishes to confirm that a nerve is a motor nerve, rather than a sensory nerve (Duhem, 1962, p. 182). Second, in Duhem's account it is the experiments which are said to confirm, or to be in conflict with, a group of hypotheses. Quine's thesis, which he says "was well argued by Duhem" (Quine, 1961, p. 41, n. 17), is by contrast not confined to physics; and for Quine what confirms or conflicts with groups of hypotheses are not the results of experiments but rather (in the 1951 version) sense experiences.[2] Quine wrote:

> our statements about the external world face the tribunal of sense experience not individually but only as a corporate body. (Quine, 1961, p. 41)

And, further on in the same paper:

> Even a statement very close to the periphery [of our field of beliefs] can be held true in the face of recalcitrant experience by pleading hallucination. (Quine, 1961, p. 43)

Duhem could not have offered that ground on behalf of *his* thesis. The possibility of pleading hallucination arises no less for the physiologist than for the physicist. A thesis defensible on such grounds could not discriminate between those two disciplines.

In Quine's later formulations, the talk of sense experiences gives way to talk of stimuli. With this comes his notion of the stimulus-meaning of a sentence for a speaker, which is the ordered pair of its affirmative and negative stimulus-meanings. Its affirmative stimulus-meaning is "the class of all stimulations (hence evolving ocular irradiation patterns between properly timed blindfoldings) that would prompt his assent" (Quine, 1960, p. 32). Negative stimulus-meaning is defined similarly, with "dissent" in place of "assent." In this later framework, the Quine thesis becomes the claim that sentences about the external world cannot be assigned stimulus-meanings one-by-one, but only collectively, in sets.

This version of the Quine thesis is plausible, but it supports holism about meaning only if meaning is to be elucidated in terms of stimulus-meaning. Identity of stimulus-meaning is far from necessary for identity of meaning. Creatures with very different sensory systems

could mean the same thing, on an occasion, by an utterance of the sentence "This edge is straight," even though their different patterns of sensory receptors preclude identity of stimulus-meaning. Nor do the sensory systems have to be radically different for the point to hold. For someone who knowingly has a serious case of astigmatism, the stimulus-meaning of "That line is straight" will differ from its stimulus-meaning for his better-sighted friend. Yet the sentences have the same meaning for both. The lesson of such simple examples is twofold. Meaning must be keyed more strongly to the environment; and we cannot hope to capture the nature of a person's grasp of meaning by looking solely at incoming information, to the neglect of the person's later use of that information, including ultimately its effects on his actions. Invited on many occasions to endorse a firmer separation of meaning from stimulus-meaning, Quine has persistently held fast to his later formulations: "I did intend the stimulus meaning to capture the notion of meaning – for the linguistic community in the case of an observation sentence, and for the individual speaker in the case of many other occasion sentences" (Quine, 1986, pp. 427–428).

Does Duhem's thesis imply a form of meaning holism? We can formulate the crucial question more generally, and also more explicitly. Let us say that a given branch of discourse *has the Duhemian property* just in case it is only whole groups of statements in that branch of discourse which are confirmed by experiments or observable states of affairs, rather than individual statements. So a branch of discourse is Duhemian if and only if it is as Duhem thought physics to be. We can now formulate our question thus: Are the distinctive terms of a Duhemian branch of discourse such that their understanding-conditions involve all the other terms of the whole language?

There are two reasons we should not give an unrestricted affirmative answer. The first is that there are some examples of areas of discourse which have the Duhemian property, but where the most plausible explanation of the phenomenon does not involve any global holism about the meaning of its distinctive terms. One example is discourse about persons' intentional states, and the actions they explain. Any particular action may potentially be explained by indefinitely many combinations of beliefs and desires. Even if one is given in advance both that a particular event is an intentional action, and the description under which it is intentional, nothing follows about which mental states of the person whose action it is were operative in producing the action. In general, actions are produced only by combinations of beliefs and desires. Correlatively, their occurrence can confirm or disconfirm only whole sets of hypotheses about the agent's mental states. There is disagreement about what grasp of the scheme of explanation of intentional states involves – whether it involves approximate laws, or whether it involves some irreducible notion of making something intelligible, to mention two of the options. But it cannot be plausibly suggested that the concepts of all the other sciences have to be brought in to explain what is involved in mastery of the scheme of intentional states. Any evidence may, indeed, be relevant to such questions as that of whether certain normal conditions, which may be required for perception, or reasoning, or intentional action are met; but this is holism of the evidence, not meaning holism.

What holds for intentional psychology may also hold for other areas of discourse. The language a person employs may be divisible into many different parts, and the discourse of each part may have the Duhemian property, without any form of global meaning holism being true of the language as a whole.

The second reason against saying that any Duhemian branch of discourse supports a form of global holism is more fundamental, and indeed, if correct, suggests that the first

reason may already be implicitly conceding too much. Why should the meaning of a theoretical hypothesis, or of a set of them, be elucidated in terms of its or their consequences for observable states of affairs at all? A scientist may formulate this hypothesis: "There are particles of matter less than 0.000001 mm in diameter, which exert tiny forces on each other." It is initially quite implausible that in order to understand this hypothesis, the scientist must know observational tests for sets of hypotheses containing it. On the contrary, attaining knowledge of observational tests for this or any other hypothesis takes reasoning and creative thought. Such knowledge usually comes after understanding of the hypothesis, and so cannot be identified with the understanding. The capacity for understanding the hypothesis is present as soon as the thinker has a general notion of size, its measurement, of matter, and of forces. This understanding must indeed ultimately connect the measurement of size at various points with the observable, and a detailed account of the nature of that connection should be given. But it is one thing to state that such connections must exist for anyone who understands measurement; it is quite another to say that the meaning of a set of hypotheses is given in terms of their observational consequences. Grasp of systems of measurement for the various physical magnitudes mentioned in the special theory of relativity no doubt involves some indirect connection of values of these magnitudes with observables. But it took further thought to devise an observational test of the theory.

From the standpoint of this second reason, the first reason implicitly conceded too much in not contesting the claim, even for the non-global holism of the scheme of intentional explanation, that the meaning of its hypotheses are given by connections with the actions they explain. It can equally take creative thought to reason out what actions would be evidence, in the context of others a subject possesses, of a given propositional attitude. In this case, too, knowledge of what would be evidence is subsequent to understanding of the sentence which attributes the given attitude. Knowledge of what would be evidence cannot be identified with understanding that sentence.

3 Does Revisability Support Meaning Holism?

The rational revisability of statements has loomed large in discussions of holism. In "Two dogmas of empiricism," Quine argued that on the conception of empirical content he presents there, "no statement is immune to revision" (Quine, 1961, p. 43). In Putnam's discussion of "the considerations that lead *me* to embrace meaning holism," he highlights the rational, non-stipulative revisability of a vast range of statements (Putnam, 1986, pp. 406 ff.). I turn now to consider the relations between revisability and holism; and also to distinguish two rather different sources of revisability.

Meaning holism does not by itself imply unlimited revisability. Those forms of meaning holism which admit certain canonical methods – the forms which accept (GHEC) of §1 above – actually preclude unlimited revisability, since according to them suitable uses of the canonical methods will not be revisable. The same holds for more limited forms of holism which admit canonical methods. Canonical methods are in effect acknowledged in Quine's later thought, in which those principles to which assent is ensured by his 'verdict tables' are taken as having an innocent kind of analyticity (Quine, 1974, pp. 77–80). Only those forms of meaning holism which do not distinguish any methods at all as canonical entail unlimited revisability. It is a real question whether these forms can make any sense of the immediate acceptance of certain statements as being required by reason, and of certain transitions

as being required by reason. Some of these forms are certainly excluded by the fact that we could never rationally revise statements of the form "If *p*, then *p*."

Does Duhem's thesis imply some kind of revisability which in its turn supports meaning holism? It cannot, if the considerations of the previous section were correct. I argued that Duhem's thesis does not imply meaning holism. If that is right, Duhem's thesis can hardly imply something which in turn implies meaning holism. But it is well worth considering what kinds of revisability are present in Duhemian areas of discourse (in the sense of the preceding section), in order to distinguish them from examples of revisability which have a different source.

A paradigm case of revisability of the sort which impressed Duhem is the attribution of a particular numerical value to a theoretical magnitude, ascribed to a particular object (or region) at a particular time. When this sort of attribution is made on the basis of experimental data, it seems indisputable that the attribution would have to be revised if, as could well be the case, we came rationally to change our mind about the principles linking the theoretical magnitude with the observable properties of the experimental setup. But besides being no challenge to central laws of logic, revisability of such particular ascriptions of theoretical magnitudes to particular objects is also consistent with the unrevisability of statements of certain very general characteristics of theoretical magnitudes or properties. A magnitude that has theoretical links with neither mass nor repulsion and attraction could hardly be the magnitude of force. Something which has nothing to do with heritable characteristics could hardly be a gene. Duhem's thesis does not exclude such simple examples of unrevisability.

Revisability with a rather different source can be illustrated if we take, first, perceptual demonstratives. Consider the perceptual demonstrative "that plant," which is in a suitable context a way of thinking of a particular plant made available by the plant's being presented to the thinker in perception in a particular way. The thinker may radically revise his view of various statements of the form "that plant is thus-and-so" without "that plant" losing its reference nor, more importantly for our concerns, its sense. These radical revisions may involve change of belief about the plant's origins, its sources of energy, its mode of reproduction, its lack (or otherwise) of magical properties, and much else. Revision on any of these matters does not affect the sense of the demonstrative expression, because no such revision undermines the foundation of the availability of the perceptual-demonstrative way of thinking of the object, *viz*. its being, in virtue of its causal relations to his perceptual state, the one which is presented to him in a certain way in perception. More generally, we can describe a kind of sense (or mode of presentation) as *causally linked* if a correct statement of what is required for something to be the reference of a sense of that kind mentions the causal relations of that thing to the thinker. Perceptual demonstratives constitute just one of many causally linked kinds of sense. Another type is that of recognitionally based senses; a further kind is that whose instances have their references fixed in part by their being the dominant sources of certain dossiers of information.[3] In these, as in other causally linked cases, recognition of radical error, and hence radical revision of beliefs, is consistent with constancy of sense. Many of Putnam's most striking examples of revisability are ones which turn on a causally linked way of thinking of some property or magnitude (Putnam, 1986).

Rational revisability made possible by causally linked senses does not seem to me to give any grounds for meaning holism in the sense distinguished in §1 above. Examples of such rational revisability are consistent with the predicates whose ascription is revised having understanding-conditions which do not make reference to the whole language. Nor is it

plausible that the understanding-conditions of the expressions with causally linked senses presuppose understanding of all the rest of the language. The crucial element in the understanding-conditions for those expressions is that the thinker's use of them be suitably answerable to information coming via the causal channel or channels which make available to the thinker the example of the causally linked kind in question. A thinker with only a fairly primitive vocabulary and conceptual repertoire can be making use of the same instance of a causally linked kind as a powerful theoretician.

Quine's arguments for holism and his insistence on extensive revisability have been linked in his writings with a rejection of analyticity, understood as truth "purely in virtue of meaning." If we reject the holism, and assert that revisability is more limited than Quine allows, are we thereby committed to the existence of sentences true purely in virtue of meaning? We are not. It is entirely open to one who rejects holisms of a Quinean sort to agree nonetheless that no sense can be made of truth purely in virtue of meaning. Any sentence, if true, can be said to be true in virtue of its disquoted truth-condition, as Quine himself has long insisted. From the standpoint of more recent approaches to meaning, the possibility of any sentence's being "true purely by virtue of meaning" remains highly questionable. Suppose we have a truth-conditional approach to meaning. Then for each of the expressions in a sentence, its meaning is given by its axiom in that theory of truth which can serve as a meaning-theory for the language. What could being "true purely in virtue of meaning" amount to in this framework? The best candidate would be that the truth of a sentence so classified is derivable solely from the axioms of the truth theory dealing with the individual components of the sentence. But in that case, it is certain that no sentences are true purely in virtue of meaning, because the meaning-theoretic axioms have to be supplemented with logic if theorems are to be derived from them. Under this elaboration of "truth in virtue of meaning," a logical truth can be shown to be true in virtue of the meaning of its component, *plus* logic. This does not look like an alternative to the principle that every sentence is true in virtue of its disquoted truth-condition; rather, it looks like a special case of it. Indeed, the most obvious way to derive the outright truth of a logical truth in the truth theory is first to derive a T-sentence for it; then to prove outright, using logic alone, that the right-hand side of the T-sentence holds; and then to apply modus ponens right-to-left on the biconditional which constitutes the T-sentence. All this amounts to is showing that the sentence has a (canonical) truth-condition, and that its truth-condition holds.

What does, arguably, come with limited revisability and canonical methods is not analyticity, but rather a form of the *a priori*. It is plausible that semantic values are assigned to expressions in such a way that canonical methods involving those expressions are always truth-preserving. If this is correct, application of a canonical method will be truth-preserving, however the actual world may turn out to be. This sounds very close to a traditional form of the *a priori* (cp. Peacocke, 1993a). But it does not resuscitate truth-purely-in-virtue-of-meaning. A conditional sentence whose antecedent captures the input, and whose consequent expresses the output, of a canonical method can be said to be *a priori*; but it is still true in virtue of the holding of its disquoted truth-condition. Similarly, a canonical form of inference is truth-preserving because every instance is such that, if the truth-conditions of its premises are met, so are those of its conclusion. Recognition of canonical methods and a rejection of holism about meaning does not require one to side with Carnap on the possibility, or even the intelligibility, of truth purely by convention.[4] (For further relevant discussion, see Chapter 23, ANALYTICITY.)

4 Do Interpretational and Compositional Considerations Support Meaning Holism?

In a famous paper, "Truth and meaning," Davidson wrote:

> If sentences depend for their meaning on their structure, and we understand the meaning of each item in the structure only as an abstraction from the totality of sentences in which it features, then we can give the meaning of any sentence (or word) only by giving the meaning of every sentence (and word) in the language. (Davidson, 1984, p. 22)

This is naturally read as a statement of global holism about meaning. But when considering the doctrine that the meaning of an expression is understood as an abstraction from the totality of sentences in which it occurs, we need to distinguish a constitutive from an epistemological version. The constitutive version states that *what it is* for an expression to have a certain meaning is to be explained by mentioning what can be abstracted from properties of whole sentences in which it occurs. It may help to draw a parallel with another constitutive thesis of abstraction. It is very tempting to hold that what it is for a given number to measure a particular object's mass (or other physical magnitude) is to be explained by mentioning the way in which that number simply codes a certain place that the object has in a system of physical relations which do not involve numbers. The numerical value of the physical magnitude does no more than abstract from a certain place in a system of relations. Representation theorems of the sort proved in the theory of measurement then allow us to say this: for an object to have a certain number as its mass is simply for it to be mapped to that number by the unique mass function which (a) takes a certain object as the unit mass, and (b) conforms to the two principles that the mass of x = the mass of y iff x has-the-same-mass as y, and that for non-overlapping objects, the mass of their sum is the sum of their masses. The constitutive thesis of abstraction for numerical values of physical magnitudes is very attractive. We seem completely unable to offer any constitutive account of what it is for an object to have, say, a mass of 5 grams which does not mention such abstraction. This is to agree with Field in denying what he calls 'heavy-duty Platonism' (Field, 1989, pp. 186–193).

The weaker, epistemological version of the thesis of abstraction for the case of meaning agrees that in coming to know the meaning of an expression we do not understand, evidence from the use of any sentence containing the expression may be relevant. But this point about evidence does not support global holism about meaning. Rather, evidence about any sentence containing an expression may be relevant to learning which one of several non-globally individuated meanings it possesses. Considerations in favor of the stronger, constitutive thesis must go beyond those which could equally be accommodated by the epistemological thesis.

There are two closely related problems for the holistic, constitutive thesis of abstraction in the case of meaning. The first problem is whether there exists any meaning-free level of properties and relations of sentences from which their meanings can be abstracted without dependence on meaning-involving notions. It is true that in Davidson's earlier accounts of radical interpretation, the fundamental level of evidence available to a radical interpreter was said to be that of holding a sentence true, an attitude which, it was emphasized, can be known to be present without knowing what the sentence means. In the earlier work, the constraint on a theory of truth as providing an interpretation of the language was said to be that of maximizing true belief, under the theory of truth in question (the "Principle of

Charity"). This constraint, too, is stated without attributing, or making hypotheses about, particular meanings. Davidson's later writings formulate the constraint on acceptable interpretations as that of maximizing intelligibility. As Grandy (1973) and McGinn (1977) emphasized, this diverges from the Principle of Charity. It is acceptable to attribute intelligible error; it is unacceptable to attribute inexplicably correct belief. Fulfillment of the constraint of maximizing intelligibility must involve the fulfillment of constraints for each particular content *p* which may be judged. If the belief that *p* is ascribed under an interpretation of the language-user's linguistic and non-linguistic behavior, then the language-user's behavior and attributed attitudes must be intelligible in the light of his believing the particular content that *p*. This is disanalogous to the relation between numerical values of physical properties and the underlying non-numerical physical relations from which they are abstracted. (It is as if there were particular constraints relating to an object's having a mass of 5 grams which any assignments of mass had to satisfy! See further Chapter 13, RADICAL INTERPRETATION.) In particular, this constraint on ascriptions of beliefs that *p*, and the general constraint of maximizing intelligibility, simply use intentional notions. They are not meaning-free accounts of how constitutive abstractionism might be true.

This difference between a constitutive abstractive thesis about meaning and other constitutive abstractive theses need not be fatal if the constraints relating to particular contents could be elucidated without taking for granted the notion of meaning or content. One could conceive, for example, of an alliance between the constitutive abstractionist about meaning and a conceptual-role theorist of meaning, one who insists that meaning is captured only by global conceptual role. This leads us, though, to the second problem.

Accounts have gradually been emerging of what is involved in mastering various particular concepts – in particular demonstratives (Evans, 1982), logical concepts, and observational concepts (Peacocke, 1992). These accounts have not adverted to the global conceptual role of the concept treated. They have, rather, concerned certain canonical circumstances for applying the concept, and certain canonical commitments involved in applying it. If these accounts are, even in principle, along the right lines, then it is not true that the meanings of words expressing these concepts are constitutively dependent upon properties of all the sentences in which they occur. For one who accepts such accounts, it is their existence which makes the case of meaning unlike that of the assignment of numbers as values of physical magnitudes (at least in the respect we have been discussing).

Interpretationists and others would, of course, doubt that these accounts can be completely correct if they purport to exhaust what individuates a meaning or concept. But this doubt need not push an interpretationist in the direction of global holism. It is open to the interpretationist to say that what makes it the case that a word expresses a particular observational concept is dependent upon the intelligibility of a person's use of the expression in certain perceptual circumstances, together with what he is intelligibly prepared to infer from the applicability of the expression in other circumstances. Similarly, the doubts of non-interpretationist objectors about the exhaustiveness of the offered accounts are more likely to concern their (somewhat) reductive features than their failure to embrace global holism.

It is important to note two points about the position which accepts the merely epistemological version of the abstractionist claim, while rejecting the stronger constitutive, holistic version. First, the merely epistemological version can still endorse the view that interpretation is answerable to global constraints of rational intelligibility. The core of the intelligibility requirements for each meaning attributed can be given by the thinker's satisfaction of the non-holistic possession condition for the concept expressed by an expression with that

meaning. The totality of such requirements for each meaning attributed gives a global set of requirements for an interpretation, a set answerable to the interpretee's use of any sentence in his language. The non-holistic interpretationist is then equally entitled to make the point that interpretation is answerable to global constraints of rational intelligibility. The global background constraint of maximizing intelligibility as applied to non-linguistic as well as linguistic actions is also applicable throughout the enterprise of interpretation. It, too, is independent of holism about meaning.

The second point to note is that the merely epistemological version of the abstraction claim can insist that an expression has linguistic meaning only if it is capable of combining with others to form complete sentences (when it is not already a complete sentence), and that this is so as a constitutive matter. Such an uncontroversial doctrine does not entail global holism about meaning. It also neither entails nor precludes less extensive holisms.

Reference and satisfaction are thought of very differently under the constitutive and the merely epistemological versions of the abstraction claim. Under the constitutive, holistic version, the correctness of attributions of referential relations to terms and of satisfaction conditions to predicates is exhausted by their role in contributing to the truth-conditions ascribed to individual sentences by a theory of truth. Consistently with his constitutive version of the abstractionist claim, this is precisely Davidson's position:

> these notions [satisfaction, reference – CP] we must treat as theoretical constructs whose function is exhausted in stating the truth conditions for sentences. … A theory of this kind … assigns no empirical content directly to relations between names or predicates and objects. These relations are given a content *indirectly* when the T-sentences are. … [Reference] plays no essential role in explaining the relation between language and reality. (Davidson, 1984, pp. 223, 225)

On Davidson's view, a particular truth theory "can be supported by relating T-sentences, and nothing else, to the evidence" (Davidson, 1984, p. 223).

There are at least three possible views about the role of reference in the explanation of facts about the truth-conditions of whole sentences. It seems to me that the correct view is intermediate between two extremes. At one extreme, we have the view which treats the role of reference as entirely analogous to the role of microproperties and microentities in the physical explanation of macrophenomena. If we have a realistic attitude to these physical theories, we will insist that the content of a statement about microphenomena is not exhausted by its role in the theory. We will also insist that it is neither constitutive nor necessary of microphenomena that they play that role in the explanation of macrophenomena. The macrophenomena might not even exist, consistently with the existence of the microphenomena and entities appealed to. The properties of carbon atoms explain the macroproperties of diamonds, but carbon atoms with their microproperties could still exist even were there not to be any diamonds. Davidson does in fact compare his own view of the status of the relation of reference, as expressed in the passages quoted in the preceding paragraph, with the status of the postulation of a fine structure in physical phenomena which explains macrophenomena (Davidson, 1984, p. 222). But the points just made about a realistic attitude to physical theories seem to me to show that a parallel with physical theory could be accepted by someone with a Davidsonian attitude to reference only if he took some form of instrumentalistic attitude to statements about microphenomena.

It does not seem correct simply to assimilate the role of axioms of reference in a semantic theory to axioms postulating microproperties and microentities in a physical theory. It should be agreed, even by the merely epistemological abstractionist, that, as an *a priori* and constitutive matter, the correctness of an axiom stating the reference of an atomic expression in a language is answerable to facts about complete sentences containing the expression. Truths about the relation of reference for atomic expressions cannot have the same metaphysical, constitutive independence of facts about the truth-conditions of complete sentences which microphenomena have from (at least certain) macrophenomena. It certainly seems that we cannot make sense of an atomic expression having a certain reference except in so far as its doing so contributes to the semantic properties of complete sentences in which it occurs. For this reason, there is at least one respect in which the view of reference which accompanies the merely epistemological version of the abstractionist doctrine need not be treating the concept of reference "as a concept to be given an independent analysis or interpretation in terms of non-linguistic concepts" – which is what Davidson was concerned to avoid (Davidson, 1984, p. 219).

At the other extreme we have the view that if the T-sentences of two semantic theories are the same, and are both well confirmed, then the two theories are equally good. This is an extreme form of instrumentalism about the semantic properties of sub-sentential expressions. This view has been vigorously contested – refuted, it seems to me – in the literature on tacit knowledge (see for instance Davies, 1987; Evans, 1981). The arguments are discussed elsewhere in this volume (see Chapter 12, TACIT KNOWLEDGE). What is important here is that there is a middle position between extreme instrumentalism and the view that treats semantic theory as analogous to physical theory. Claims about the reference of an atomic expression are constitutively and *a priori* answerable to facts about whole sentences containing it. But when a particular referential axiom for an expression *a* is correct, the explanation of a person's use and understanding of sentences containing *a* has a certain structure. Suppose a proposed axiom states that *a* denotes Paris. If speakers of the language happily assert all sorts of sentences of the form "*a* is thus-and-so" without checking on anything about Paris, and without taking themselves as answerable to anything about Paris, that is strong evidence against the proposed axiom. Generally, in the enterprise of maximizing intelligibility, a proposed axiom which states that an expression refers to a certain object is answerable to the role of the properties of that object in the explanation of speakers' sincere assertions containing the expression. More specifically, when the axiom "*a* denotes Paris" is correct for a language as understood by a given person, there is a common component in the explanation of all the various cases of his understanding of a sentence containing *a* as meaning something about Paris. The common component of each explanation is just his possession of the information stated in the axiom "*a* denotes Paris."

There is a great deal more to be said on many aspects of this middle position, but I hope enough has been said for us to be able to identify the two properties which distinguish it from the two extremes. On the middle position, it will be agreed that there is a sense in which it is *a priori* that: if *a* denotes Paris, and *f* is true of anything just in case it is elegant, then *fa* is true iff Paris is elegant. A full statement of the *a priori*, constitutive features of the relation of reference precludes assimilation of its status to something analogous to that of theoretically postulated relations in physics. But these *a priori* links in no way rule out the possibility that a person's possession of the information that *a* denotes Paris contributes causally to the explanation of his knowledge that *fa* means that Paris is elegant. There is such explanation when understanding is suitably structured; and so the middle position is also distinguished from the other, instrumentalist, extreme.

5 Global Holism, Justification, and Semantic Value

Dummett describes the holist thus:

> For the holist, we ought not to strive to command a clear view of the working of our language, because there is no clear view to be had. We have a haphazard assembly of conventions and rules, and there are no principles which govern our selection of them or render them any more appropriate than any others we might adopt. (Dummett, 1991, p. 241)

But we should, Dummett holds, subject any language to a critical scrutiny which

> aims at a systematic means of ascribing *content* to the expressions and sentences of the language, in terms of which accepted modes of operating with it (including the rules of inference observed) can be justified, or, better, are evidently justified. (Dummett, 1991, p. 241)

It was not written into our original formulations of holism – (GH), (GHE), and their variants – that such justification is unavailable. We also noted, towards the end of §1, that certain types of holist could endorse the notion of the content of an individual sentence. So we should consider separately types of holism which do, and types of holism which do not, make the claim that content-based justification is impossible. Let a *warranting* form of holism about meaning be a form which meets these two conditions. (1) The form of holism is committed to holding that there is a notion of justification on which certain assertions, made in appropriate circumstances, are warranted, in part by virtue of their meaning (and similarly for certain transitions between sentences). (2) This relation of justification is sufficiently powerful to rule out certain otherwise apparently satisfactory, fundamental specifications of alleged meanings (or understanding-conditions) as legitimate. We can say that a form of holism is *warrant-free* if it is committed to holding that there is no notion of justification meeting the conditions (1) and (2). It is a warrant-free holism which "sanctions the claim that we have a right to adopt whatever logical laws we choose" (Dummett, 1991, p. 227).

A warranting holism may be either conservative or revisionary of our actual judgmental and inferential practices, according as actual practices do or do not meet the standard of justification favored by the warranting holism. The scope for a revisionary warrant-free holism is much narrower. Some such scope no doubt exists. For example, a warrant-free holist may also believe in a form which classifies some methods of forming judgments as canonical; so the actual inferential practice of an individual may be criticized as not properly related to the canonical methods for the communal language. But this is a very limited kind of case. What warrant-free holists cannot coherently do is to criticize a practice as not meeting the requirements for justification, where justification is of the sort mentioned in conditions (1) and (2).

Our question must now be: Is either warranting holism or warrant-free holism about meaning tenable?

Warrant-free holism faces the problem of the existence of rules for certain expressions which lack meaning. These rules are in no way circular or infinitely regressive; but they fail to determine a meaning for the expressions they treat. Intuitively, they fail precisely because what is said in the proposed rules makes it impossible to see what the contribution of these expressions to the content of complete sentences containing them could possibly be. The

most well-known and spectacular case of this is the example of Prior's connective *tonk*, whose alleged sense is introduced by the two rules that from *A* one can infer *AtonkB*, and from *AtonkB* one can infer *B* (Prior, 1960). The rules for *tonk*, if accepted, clearly lead to the provability of all formulae. There are, though, other examples in which a proposed set of "rules" is not inconsistent (nor leads to radically non-conservative extensions of systems to which it is added), but fails to determine a meaning.

In earlier work, I mentioned the example of a spurious quantifier *Q* (Peacocke, 1993b). *Q* is said to have the same introduction rule as the existential quantifier: from $A(t)$, one can infer $QxA(x)$, subject to the usual restriction on the variables. *Q* is also said not to have any other introduction rules, and it is further said that the analogue of the existential elimination rule is invalid for it. There is a powerful intuition that no meaning is fixed by these rules. What could $QxA(x)$ possibly mean? It must mean something that can be inferred from any instance. Yet it cannot mean the existential quantification of $A(x)$, otherwise the elimination rule would be valid. It cannot mean something equivalent to the holding of an alternation consisting of that existential quantification with some further condition *p*. For then there should be a further introduction rule, that $QxA(x)$ can be inferred from *p* – yet there were said to be no further underived introduction rules. This argument that *Q* has no meaning is quite general, and applies under both constructivist and more realistic conceptions of content. The example is one of many. Similar points could be elaborated for the equally problematic connective "*Ü*," which was introduced and exposed by Dummett (1991, pp. 288–290). *Ü* is supposed to have the same introduction rule as ordinary alternation, but a more restricted elimination rule. The reader can develop an argument entirely parallel to that given for *Q* that there can be no contribution to the meaning of complete sentences containing it made by *Ü*.

It is highly plausible that what is wrong with all of these spurious connectives and operators is that the specifications placed upon them prevent them from having semantic values, appropriately related to their specifications, which contribute to the determination of the truth-value of complete sentences in which they occur. The rules for *tonk*, for example, place inconsistent requirements upon the truth-value of *AtonkB*, for the line of the truth table in which *A* is true and *B* is false. If *AtonkB* is counted as true under those conditions, then the second rule for *tonk* will lead from true premises to a false conclusion when *A* is true and *B* is false. But if *AtonkB* is counted as false under those same conditions, the first rule will then lead from truth to falsity.

It is at this point that the warranting holist is likely to intervene in the discussion, and advertise the virtues of his position. After all, he may say, if the defect of these spurious connectives is the impossibility of giving a coherent account of their contribution to semantic value, then what is wrong with them is not obviously anything to do with holism. So why should there not be a warranting holism which, unlike warrant-free holism, insists that any specification of a genuine meaning (perhaps by means of an understanding-condition) must admit a corresponding account of its contribution to semantic value, but which remains a form of holism nonetheless?

Warranting holism faces two closely related problems, which I call the *overdetermination* problem and the *overdiscrimination* problem. We can illustrate the overdetermination problem for the simple case of "and." It is plausible that the understanding-condition for this expression of English involves some kind of mastery of the introduction and elimination rules for conjunction, and that (for a realist, at least) the semantic value of "and" is that classical truth-function which makes those rules always truth-preserving. But for a thinker

who possesses the concept of probability, "and" will feature in other principles too. Such a thinker will have some form of mastery of the principle that if A and B are independent propositions, then $\text{prob}(A\&B) = \text{prob}(A) \cdot \text{prob}(B)$. If we ask what semantic value for "&" would make this principle always correct, again the classical truth-function for conjunction is the answer. So the total set of principles essentially involving "&," acceptance of which is required if the thinker is to understand the expressions they contain, overdetermines the required semantic value.

Why is this a problem? It is a problem for the warranting holist, because it is a datum which can easily be exploited by an opponent of global holism about meaning. The opponent will say that this state of affairs is symptomatic of the fact that only a subset of principles essentially containing "&" are constitutive of its meaning (the introduction and elimination rules). It is they which fix its semantic value, which is then drawn upon and presupposed by someone who starts using the concept of probability in combination with logical connectives like conjunction. This is why the principles of probability can be justified without appealing to those principles themselves as partially fixing the semantic values of the logical constants, the anti-holist will say. Our warranting holist may reply that all principles essentially containing "&" are on a par. But that reply is quite implausible about "&."

The overdetermination problem is on one side of a coin which has the overdiscrimination problem on its other side. The more principles we include as individuative of the meaning of an expression in a person's language, and thereby as contributing to the determination of its semantic value, the wider is the range of cases in which we are precluded from identifying its meaning with that of an expression in the language of a person with either a much richer or a much narrower vocabulary. In one of his earlier writings on the topic, Dummett ascribes to the holist the view that "deduction is useful, because by means of it we can arrive at conclusions, even conclusions of the simplest logical form, which we could not arrive at otherwise" (Dummett, 1978, p. 303). But in fact that is precisely what we cannot do on the holist's view of meaning. According to the holist, when we enrich our vocabulary the meaning of all our expressions changes, and a conclusion we reach with the methods involving a new concept, though it may be grammatically the same as one formulable in the old vocabulary, does not actually have the same meaning as its orthographically identical predecessor. As a result of this overdiscrimination of meanings, the territory in which a global holist can also justifiably, by his own lights, apply a notion of warrant that is unavailable on the warrant-free conception is really quite limited.

6 Local Holisms and Their Source

Sometimes, perhaps always, a thing (property, relation) is individuated in part by its relations to other things, properties, or relations. What it is to be that thing, property, or relation cannot be properly explained without mentioning those other things, properties, or relations. I mention three kinds of case, each familiar from discussions in different areas. First, what it is to be a particular place cannot be explained without mentioning the network of spatial relations in which the place stands. A second plausible example involves mass and force. What it is for something to be the physical magnitude of mass cannot be elucidated without alluding to the fact that things with mass require the action of a force for a change in their motion, and are capable of exerting forces when their state of motion changes. Conversely, the physical magnitude of force is individuated in part by its connections with

the physical magnitude of mass. Third, the property of having a certain linguistic meaning is individuated in part by its connections with the property of believing something with the same content. It is partially constitutive of meaning that it can be used to express beliefs (and even, I would argue, knowledge).[5]

All these claims about what is constitutive or individuative of an object, property, or relation are, in the first instance, claims about things at the level of reference, rather than at the level of sense. They are claims about the things or properties themselves, rather than about those things or properties as thought of in a certain way. It is true that one often formulates such points by saying, for example, "The concept of mass is the concept of a property which, when instantiated requires the action of a force for …." But when one uses such a formulation, one is employing that concept or way of thinking of mass which makes explicit the way in which the property to which it refers is individuated. I say that the claims are "in the first instance" about things at the level of reference, because the point I wish to emphasize does not preclude the possibility that further philosophical analysis may reveal that these constitutive facts about the level of reference may ultimately themselves have an explanation which involves other facts about the level of sense. A parallel may help to make the point. Kripke's arguments have made a strong case that it is necessary, of Peter Serkin, that his father is Rudolf Serkin (Kripke, 1980). This is a *de re* claim about Peter Serkin himself, and not about some mode of presentation of him, and it is arguably constitutive. In any case, let us suppose that it is so, for the sake of the illustration. It does not follow that the ultimate source of *de re* necessities of origin is not some *a priori* principle stating that continuant objects necessarily have their actual origins, a principle whose *a priori* status traces back in part to the sense of "continuant object." That is a separate question, and neither a positive nor a negative answer to it undermines the fact that the original essentialist claim about Peter Serkin involves the man himself, and not some concept of him.

In our three examples, there will be a local holism for the meanings of expressions for (and equally for concepts of) places and spatial relations; for expressions for mass and force; and for expressions for meaning and belief. In each case, what it is to understand an expression for one of these things will have to be given simultaneously with an account of what is involved in understanding (or at least possessing a concept of) the other. These local holisms are entailed by the conjunction of two plausible claims. The first claim is that when one thing (property, relation) rather than another is the reference of a word, there must be some fact about the use of that word which, possibly together with the way the world is, fixes it and nothing else as the word's reference. We can call such a fact about the use of the word or concept "the reference-fixing fact." The second claim is that the reference-fixing facts for words referring to the things and properties in our three examples involve the language-user's rudimentary grasp of the constitutive relations of the thing or property in question to other things or properties. If these claims are sound, then local holisms of meaning are derivative from holisms at the level of the individuation of properties and things.

Grasp of these interrelations is not, of course, and could not be, the only element in an account of mastery of these expressions. There are practical components, involved in the explanation of spatial actions, in the understanding of expressions for places and spatial relations. The same holds for mass and force. Some would argue that there are first-person elements in the grasp of the concepts of meaning and belief. But in all three cases, it is plausible that understanding expressions for the things or properties comprising the local holism involves some form of knowledge of their role in theories capable of explaining respectively, in the three examples, spatial facts, mechanical facts, and facts about intentional action.

* * *

Even if the general arguments for meaning holism are not convincing, there remain a great many intriguing questions about more local holisms. Some of these questions are questions about particular examples. What, for instance, is the relation between practical spatial abilities and mastery of concepts of places and spatial relations? Can a family of practical abilities also display a form of holism? Beyond the questions about particular examples, there are also general questions about kinds of local holism, to which the answers about particular examples are pertinent. Is it always possible in principle to specify the nature of the connections a thinker has to grasp between the properties and objects involved in a local holism without presupposing some mastery of the very concepts involved in the holism? If not, that would seem to count in favor of a version of anti-reductionism about mastery of those concepts. And whatever the answer to that general question, what could or should be the shape of a computational psychology which explains, at the sub-personal level, mastery of a local holism? As far as I know, all these questions are open. Even if global holism is false, the topic of holism deserves to be with us for some time to come.

Notes

1 The arguments for meaning holism have been subjected to a lively critique in Fodor and LePore (1992). Though Fodor, LePore, and I agree in our major conclusions, the arguments for them are rather different, and also venture into different territories. For those wanting a critical overview of discussions about meaning holism, I believe that Fodor and LePore's book and the present chapter will be found complementary, rather than intersubstitutable.

2 Moulines (1986) and Vuillemin (1986) each provide an interesting discussion of the first of these differences between Duhem and Quine, but both pass over the second difference.

3 For an important discussion of the sense of natural kind terms pertinent to these points, see Wiggins (1980, pp. 78–84).

4 It should be noted that my rather strict use of 'analytic' diverges from that of Fodor and LePore (1992). As far as I can see, many of the claims Fodor and LePore make about the analytic/synthetic distinction are ones I would formulate as claims about the *a priori*/*a posteriori* distinction (and would also then accept). This point applies in particular to their discussion of the view that there is no principled distinction between the propositions a person has to believe in order to believe a given content and those he does not (Fodor and LePore, 1992, pp. 24 ff.). It is plausible that rejection of that view does involve some commitment to the existence and applicability of an *a priori*/*a posteriori* distinction. It is not at all so clear that it involves commitment to the applicability of the notion of truth-purely-in-virtue-of-meaning.

5 If meaning and belief do indeed form a local holism, those who have argued from interpretational considerations to meaning holism have mistakenly taken an admittedly important local holism for a global holism.

Metaphor

RICHARD MORAN

Metaphor enters contemporary philosophical discussion from a variety of directions. Aside from its obvious importance in poetics, rhetoric, and aesthetics, it also figures in such fields as philosophy of mind (as in the question of the metaphorical status of ordinary mental concepts), philosophy of science (as in the comparison of metaphors and explanatory models), in epistemology (as in analogical reasoning), and in cognitive studies (as in the theory of concept-formation). This chapter will concentrate on issues metaphor raises for the philosophy of language, with the understanding that the issues in these various fields cannot be wholly isolated from each other. Metaphor is an issue for the philosophy of language not only for its own sake, as a linguistic phenomenon deserving of analysis and interpretation, but also for the light it sheds on non-figurative language, the domain of the literal which is the normal preoccupation of the philosopher of language. A poor reason for this preoccupation would be the assumption that purely literal language is what most language use consists in, with metaphor and the like sharing the relative infrequency and marginal status of songs or riddles. This would not be a good reason, not only because mere frequency is not a good guide to theoretical importance, but also because it is doubtful that the assumption is even true. In recent years, writers with very different concerns have pointed out that figurative language of one sort or another is a staple of the most common as well as the most specialized speech, as the brief list of directions of interest leading to metaphor would suggest. A better reason for the philosopher's concentration on the case of literal language would be the idea that the literal does occupy some privileged theoretical place in the understanding of language generally, because the comprehension of figurative language is itself dependent in specific ways on the literal understanding of the words used. This is at least a defensible claim and, if true, we might then hope for an understanding of figurative language from a theory of literal meaning, combined with an account of the ways in which the figurative both depends on and deviates from it.

The light such an investigation may shed on non-figurative language will derive from the issues which even this mere sketch of their relation raises for the philosophy of language. We will want to know, for instance, about the specific nature of the dependence of the figurative on the literal; and how the comprehension of figurative language is related to, and

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

different from, the understanding of the literal meanings of the words involved. If the theory of meaning in language is, at the least, closely allied with the theory of what understanding such things as sentences consists in, then a question raised by metaphor is how understanding as applied to metaphorical speech is related to understanding in this semantic sense, and whether the same kind of knowledge, such as whatever it is that 'knowing a language' consists in (see Chapter 12, TACIT KNOWLEDGE), applies in similar ways in the two cases. We will want to consider reasons for and against speaking of a difference in *meaning* in connection with metaphor, and whether such distinctive meaning is to be sought for on the level of the word, sentence, or utterance; on the level of semantics, pragmatics (see Chapter 6, PRAGMATICS), or somewhere else.

1 Figurative and Non-figurative: Metaphor, Idiom, and Ambiguity

The familiar subject–predicate form ('X is a wolf, the sun, a vulture …') comprises but one class of metaphors, and neglects various other grammatical forms (such as 'rosy-fingered dawn' or 'plowing through the discussion'), not to mention metaphoric contexts which don't involve assertion at all. And, in general, short, handy examples will not help much in the understanding of, say, literary metaphors whose networks of implications are not discernible outside the verbal environment of a particular text or genre. Nonetheless, even such simple cases can help us to make some provisional distinctions between metaphor and other figurative and non-figurative language. For instance, idioms, such as 'to kick the bucket' or 'to butter someone up,' resemble metaphors in calling for a special reading. If one understands such expressions correctly, one will not expect reference to have been made to any actual bucket or real butter. In a word, they are to be taken figuratively and not literally. (This is so even though, for instance, there is hardly anything wildly paradoxical in the idea of someone kicking a genuine bucket.) But although they both involve giving figurative readings to an utterance, there are important differences in how one comprehends the meaning of an idiomatic expression and the meaning of a metaphor. If you don't know what 'vulture' means or what plowing is, you won't be able to interpret their metaphorical expressions at all. And what one does when one interprets the metaphor is employ what one knows about vultures and what is believed about them to determine what the utterance means on this occasion. This is part of what is meant by the previous suggestion that the comprehension of figurative language is dependent on the literal understanding of the words used.

If idiom is to count as a case of figurative language (which it seems it should, since we can distinguish what it is literally to kick the bucket and the very different thing usually meant by the expression), then this claim of dependence on the literal will have to be amended. For an understanding of the literal meanings of the words that make up an idiom is of very limited usefulness in understanding what is meant, and is sometimes even positively detrimental to such understanding. Someone unfamiliar with the expression will not get very far by employing his understanding of what is known or believed about such things as buckets to figure out what the expression means. And further, if she does know a great deal about the literal meaning of a word like 'moot,' for instance, then, other things being equal, this may well render her less rather than more likely to understand what is meant by the (American) idiomatic labeling of something as a 'moot point' – that is, that the point is

of no current practical import and not worth discussing. What this means is that the meaning of an idiomatic expression is not a function of the meanings of the individual words that compose it; unlike metaphors, they are simply taught to us as wholes, rather than being a matter of individual interpretation on an occasion. (For such reasons, it has been said that "an idiom has no semantic structure; rather it is a semantic primitive." Davies, 1982–1983, p. 68. See also Dammann, 1977–1978.) And again, unlike metaphors, their meaning is simply given: there is no 'open-ended' quality to the idiom's meaning, no special suggestiveness, no call for its creative elaboration. There is a simple, stable answer to the question of what 'kick the bucket' means idiomatically, and that is why dictionaries can have special sections in them for idioms, but not for metaphors (see Cavell, 1976/1969).

Finally, the contrast with idiom enables us to distinguish some issues here concerning paraphrase. It is often said that metaphors, or at least poetic, 'live' metaphors, are not subject to paraphrase, and this is often taken to mean that they are not translatable into another language. However, there is one sense in which it is idioms and not metaphors which resist translation into another language. The overall effectiveness of certain literary metaphors will, to be sure, be influenced by certain language-specific phonetic features; but nonetheless, referring metaphorically to someone as, say, 'shoveling food into his mouth' will be possible wherever they have shovels and food, and words for these things. By contrast, translating the words of the idiom 'to kick the bucket' into Spanish or Korean will not be likely to get across your meaning, or any other meaning. The reason for this, again, is the 'semantic primitiveness' of idiomatic phrases. Since an idiom's meaning is not built up from the meaning of its individual words, this meaning will not be conveyed in another language by means of word-by-word translation (see Dammann, 1977–1978). Naturally, this doesn't mean that some perfectly good sense of 'translation' is not appropriate here. If 'kick the bucket' is one way in English of saying that someone died, then there will be perfectly good ways of translating that idea into Spanish or Korean. So resistance to word-by-word translation is not the same as the inability to express the meaning of the idiom in words of another language.

One way in which the issue of the translatability of poetic metaphor is vexed is through confusion about what might be meant by the idea of a word's acquiring a specifically 'metaphorical meaning'; and this idea will be discussed at some length later. But, in addition, there is some lack of clarity about the relation between paraphrase and translation. If all we mean by paraphrase is the ability to say what one means in other words, then it does seem true that there is a difference between idiom and metaphor here. For, as described above, the idiomatic meaning of some expression can be given in other words in a quite straightforward and definite manner. (Many idioms are euphemisms, after all, whose literal equivalents are all too straightforward.) By contrast, the paraphrase of a live metaphor is much less definite, more open-ended, more dependent on context (including the individual speaker), and more open to the creative interpretation and elaboration of the hearer. What should be noted, however, is that these are all features of the paraphrase of metaphor within a language, and do not carry over any immediate implications for the translation of metaphors across languages. Familiar ideas about the 'essential incompleteness' of any prose paraphrase of metaphor should not cloud the issue, for there is no reason in principle why the very same indefiniteness and open-ended character of a metaphor in English should not show up in its version in another language. Translation need have nothing to do with reducing the live metaphor to a prose paraphrase. And if it is argued that even good translation will not capture all and only the connotations and associations of the original metaphor, it

may be replied that to the extent that this is true at all, it will apply to cases of perfectly literal language as well, from '*Gemütlichkeit*' to 'priggish.' To sum up: within a language, the idiomatic meaning of an expression may be completely given by its literal equivalent, whereas the live metaphor is not reducible to its prose paraphrase; and across languages, an idiom cannot be translated word by word, but only as a fused whole; whereas word-by-word translation of a metaphorical expression may, in fortunate circumstances, preserve the same suggestiveness and 'open texture' as the original. In so far as metaphor involves comparison of things and ideas with other things and ideas, it is something less specifically language-bound than is idiom.

In this respect metaphors also differ from puns, homonyms, and ordinary ambiguity in language. A pun in English, like 'heart' and 'hart,' may be metaphorically exploited by a poet, but is only a homophonic accident until it is so exploited. A translation of the play into another language may well display the same metaphoric comparison, but naturally the phonetic motivation for making just this comparison will be lost with the homophony. Sometimes homophonic words are not only pronounced the same but are also spelled the same, and then we have true homonyms, like 'cape' for a body of land and an article of clothing. An inscription such as 'cape' is ambiguous between the two meanings, which need not be etymologically related at all, and once again this ambiguity may be metaphorically exploited. But neither puns nor homonyms are in themselves examples of figurative language. 'Cape' has (at least) two meanings, but they are both perfectly literal ones, and understanding one of the meanings provides no interpretive clue to the other one.

2 Metaphorical Meaning

Even this brief characterization raises deep theoretical issues, in so far as it has appealed to some notion of 'figurative meaning' at various different stages. In metaphor we interpret an utterance as meaning something different from what the words would mean, taken literally. Often we will want to say that a statement which is wildly false when taken literally is quite true when taken figuratively. And from here it is natural to reason in the following way. Truth-values cannot vary unless *truth-conditions* vary, and if the truth-conditions of an utterance are what determine its meaning, then the literal and the metaphorical interpretations of an utterance amount to differences in meaning (see Chapter 2, MEANING AND TRUTH-CONDITIONS: FROM FREGE'S GRAND DESIGN TO DAVIDSON'S). The words, or the utterance, have one meaning when intended or taken literally, and another when spoken metaphorically. In addition it was argued, in connection with idiom, that a metaphor can be translated into another language while preserving its metaphorical meaning, and in his original (1962) paper Max Black takes this to imply that "to call a sentence an instance of metaphor is to say something about its meaning, not about its orthography, its phonetic pattern, or its grammatical form" (p. 28).

Thus, some of the motivation for talking about 'meaning-shift' in connection with metaphor is clear enough; and it seems equally undeniable that, quite often, everyday metaphorical speech is successful at communicating something different from what the words, on their literal interpretation, would mean. But our brief characterization of metaphor, especially in its contrast with idiom and common ambiguity, already raises some serious questions for this way of talking about metaphor. For it was pointed out that, unlike the cases of 'kick the bucket' or 'cape,' the different reading we give to 'vulture' (when used, say,

to refer to a certain kind of human predator) is directly dependent on our understanding of the literal meanings of the individual words. Unlike an ambiguous word like 'cape,' then, in metaphor the two meanings must be related somehow. When a *token* of 'cape' is reinterpreted as having one meaning rather than another, the meaning assigned to it on the first reading is excluded, and nothing in the first reading (other than one's dawning sense of its inappropriateness) plays a role in bringing one to the second interpretation. In principle, and often enough in practice, the reader could have hit on the correct interpretation the first time, without considering any possible ambiguity, and nothing would have been thereby lost in her comprehension of what was said.

Such cases of ambiguity explain some of the motivation for individuating words according to sameness of meanings, rather than according to sameness of spelling or pronunciation. (Hence, on this view, the two 'capes' count as different words.) For a speaker does not clarify her intentions by saying she employed the same word, 'bank' (encompassing both meanings), on one occasion to refer to part of the river and on another occasion to refer to where she keeps her money. There is no point expressed in using the 'same word' in these different ways; for the two words are hardly more related in meaning than are 'kinder' in English and *Kinder* in German. In neither this case nor the case with 'bank' need the orthographic identity ever have occurred to the speaker in order to use the words correctly and to communicate her meaning fully.

Contrast this with the case of metaphor. If we think of the words of a metaphorical expression as undergoing a 'meaning-shift' of some kind, it will have to involve a difference of meaning very different from that involved in ordinary ambiguity. For when an expression is interpreted metaphorically, the first interpretation (the literal one) is not canceled or removed from consideration. The literal meaning of 'vulture' is not dispensable when we interpret it metaphorically in its application to some friend or relation. The literal meaning must be known to both the speaker and the audience for the metaphorical point of the epithet to be made. It has everything to do with clarifying the speaker's intentions that she chose this word, with its literal meaning applying to a kind of bird, to refer to this other thing which is not a bird; and when we start to figure out the reason why the speaker is using this word with its literal meaning in this context, we have begun to interpret what she is intending to get across metaphorically. Simply characterizing metaphor in terms of a change of meaning fails to capture the role of the original, literal meaning.

But the dependence of the metaphorical on the literal runs deeper than this, and raises further doubts about the appropriateness of the idea of 'meaning-shift' in metaphor; for the description of interpretation given so far might apply just as well to a situation in which a person is speaking in a kind of code, in which someone has to interpret her utterance in such a way that certain words are to be replaced by specific other ones. He might conjecture that 'vulture' is one of these words, and hit upon the right substitution for it. In such a case we might well speak of the word 'vulture' being given a different meaning or application in this context.

The case of metaphor differs from this in several ways. First, and perhaps most obviously, there is nothing corresponding to a code for a live metaphor, and no rules to appeal to for going from the literal to the metaphorical meaning. Further, in the case of genuine codes the original meaning of the words will normally be incidental, at best, to the new meaning; and in fact, a coined expression with no previous meaning in the language may do just as well, if not better. In metaphor, on the other hand, if we are to speak of a new meaning, this meaning will be something reachable only through comprehension of the

previously established, literal meanings of the particular words that make it up. And this dependence of the metaphorical on the literal is rather special, in ways that exacerbate difficulties with the view of metaphor as involving a change of meaning. For the first (literal) reading of the expression does not simply provide clues to help you get to the second one, like a ladder that is later kicked away, but rather it remains somehow 'active' in the new metaphorical interpretation. It is not similar to a case in which we first got the meaning wrong and have now successfully disambiguated it. Rather, the literal meaning of 'vulture' remains an essential part of the meaning of the metaphorical expression; otherwise one will have no sense of what metaphorical comparison is intended. If something like 'meaning-shift' is involved in this, then we must explain how the literal meaning of 'vulture' could play any role at all in the generation and comprehension of the metaphorical meaning, if it is this very same original meaning that is supposed to have changed (or, to speak a bit less confusingly, if the word has now taken on a different meaning).

It might be thought that we could avoid this problem by referring to an expansion rather than a change of meaning. That way we could retain and rely on the original meaning of the words, and still describe what is going on in terms of some change of meaning. So, for instance, 'vulture' still refers to the same birds it always did, but now, in addition, it also refers to a certain kind of person. The problem with this idea is that while it describes a certain process of linguistic change, it simply isn't what is meant by live metaphor. Words commonly expand and contract in application over time, and this process can take many forms, some of which may indeed involve metaphor at some stage. But the process itself is not inherently metaphorical, and it can proceed for any number of reasons. In earlier times, the word 'engine' applied more narrowly to instruments of war and torture, and not generally to any mechanism that converts energy into force or motion. This expansion in application does not make the latter, contemporary use metaphorical, even if we think that, for instance, certain relations of perceived similarity played a role in the expansion. And in any case, what any such analysis of 'meaning-change' in terms of merely extended application leaves out of consideration is the point insisted on above, the special dependence of the metaphorical on the literal which makes the literal meaning of a word such as 'vulture' still 'active' in the comprehension of its metaphorical use. We are still in need of an account of this 'activity,' to be sure, but there is certainly an essential functional role for the awareness of the literal meaning of 'vulture' in the comprehension of its metaphorical use which has no parallel in the understanding of various other predicates with extended applications. So we still lack an explanation of what could be meant in speaking of 'change of meaning' in connection with metaphor.

These questions will require answers just as much on an account that appeals to speaker-meaning rather than semantic meaning (Searle, 1979; Black, 1979) as it will also on 'extensionalist' accounts, which eschew talk of 'meanings' altogether in favor of reference to different applications of labels (see Goodman, 1968; Elgin, 1983; Scheffler, 1979).

3 Davidson and the Case against Metaphorical Meaning

How might we characterize the dependence of the metaphorical on the literal, specifically the way in which the literal meaning is still 'alive' in the metaphorical application, and avoid making reference to a new metaphorical meaning? And, on the other hand, if we do avoid all such reference, how can we account for the difference in truth-value between the

utterance taken literally and taken metaphorically? Further, if we drop all reference to meaning, then it will be quite unclear how we can make sense of the idea that we correctly understand the speaker as saying (or meaning) something different from what her words literally mean, or that we see metaphor as a vehicle of communication at all.

In a paper that has attracted a great deal of commentary, Donald Davidson has taken this step, and has argued that we should indeed cease talking about figurative meaning in connection with metaphor altogether; and he seems prepared to accept the consequences that follow from this rejection. Early on, he states the thesis of the paper as the claim that "metaphors mean what the words, in their most literal interpretation, mean, and nothing more" (Davidson, 1979, p. 246). He does not mean to deny that metaphor accomplishes many of the same things that philosophers and literary critics have claimed for metaphor (such as the special suggestive power of poetic metaphor, or its capacity to produce insight of a sort that may not be capturable in plain prose), but he denies that these accomplishments have anything to do with content or meaning of a non-literal sort. It will be useful to look more closely at Davidson's paper, for it is an especially forthright and radical response to many of the same problems in accounting for 'metaphorical meaning' that have emerged elsewhere in recent literature on the subject. At the same time we can gain a better appreciation of the costs as well as the benefits of rejecting 'metaphorical meaning.' (Davidson's paper is discussed in Cooper, 1986; Davies, 1982–1983; Fogelin, 1988; Moran, 1989; and Stern, 1991, and there are responses by Black and Goodman in Sacks, 1979.)

The argumentative structure of the paper is not always easy to interpret, but Davidson gives a number of reasons for the denial of metaphorical meaning, some of which are related to the argument given above and which contrast metaphor with common ambiguity. He further argues that positing metaphorical meanings does nothing to explain how metaphors function in speech. If, as he says, a metaphor makes us attend to certain covert features of resemblance (Davidson, 1979, p. 247), it tells us nothing about how this is accomplished to claim that the words involved have some figurative meaning in addition to the literal one. It is not only more accurate simply to say that a fresh metaphor typically produces such effects (in whatever causal manner anything else might do so), but it is also more economical, for we are thereby spared the need to account for what these special meanings are and where they come from. In an ordinary, literal context, appeal to meaning can be genuinely explanatory because there we can have a firm grip on the distinction between what the words mean in the language and what they may be used to do on a particular occasion (to lie, for example, or to encourage, or to complain). However, if we think of what metaphorical language is used for (such as to make us appreciate some incongruous similarity) as itself being a kind of 'meaning,' we lose any sense of this distinction. And yet one of the theoretical virtues of appeal to semantic meaning in the first place is that it enables us to explain something of how these words, with this established meaning and in this context, can be used to perform this particular function on this occasion. That is, a particular established meaning provides both constraints on and possibilities for what a word or phrase may be used to do, and for this reason appeal to such meaning (once it is determined by a given context) can be genuinely explanatory of what the phrase is on this occasion used for. But the only meaning which is distinct and independent of the use on this occasion, and which could play any such explanatory role, is the literal meaning of the phrase. (Various writers have criticized Davidson's argument for assuming a concept of literal meaning that is utterly independent of context, but it seems clear that this is not his view: see Davidson, 1979, p. 260.)

In addition, Davidson argues, when we think of metaphor in terms of the communication of a specific propositional content, we can only have in mind the most dead of dead metaphors, such as referring to the 'leg' of a table. And these, he suggests, are not properly metaphors at all. If the expression 'figurative meaning' points to anything at all, it indicates some special power of metaphor, some striking quality that may be productive of insight or creative elaboration on the part of the audience. The failure to capture anything about the distinctively figurative functioning of live metaphor Davidson sees as a further defect of the idea discussed earlier, that the meaning or application of a term is 'extended' in a metaphorical context. For if we say that the literal application of an expression such as 'vulture' is extended, we have first of all said something false, or at best misleading: as if, now, both some birds and some people were straightforwardly vultures, the way both vultures and sparrows are straightforwardly birds. And in addition, for our trouble, we have failed thereby to capture anything figurative about the whole process. And then, on the other hand, if we say that the metaphorical application of the term has been extended, then we seem to have got no further in our analysis. For we now owe an explanation of what a metaphorical application is, and specifically, how it differs from any other type of application of a term.

(For a different perspective on what are normally thought of as dead metaphors, see Lakoff and Johnson, 1980.)

4 Paraphrase and Propositional Status

The concentration on live metaphor is bound up with another strand of Davidson's case against metaphorical meaning, but one for which it is difficult to determine the weight he wants to give to the various considerations he brings forward. Whatever makes a poetic metaphor 'live,' it is certainly in large part a function of its power of suggestiveness, the fact that the interpretation of live metaphor is open-ended, indeterminate, and not fixed by rules. As Davidson says at the beginning of his essay, "there are no instructions for devising metaphors; there is no manual for determining what a metaphor 'means' or 'says'; there is no test for metaphor that does not call for taste" (Davidson, 1979, p. 245). The creative indeterminacy of live metaphor is one reason why live and dead metaphors differ with respect to the possibilities for paraphrase, or for specifying the meaning in other words. We can fully state what is meant by the 'shoulder' of a road, precisely to the extent that there isn't anything figurative left to the expression. With genuine, or poetic, metaphor the case is quite different, and at various points Davidson seems to be asking, 'How could the sort of open-ended, non-rule-governed character of live metaphor possibly apply to anything legitimately called a meaning?' When we encounter difficulties in applying paraphrase to live metaphor, the reason for this is simply that "there is nothing there to paraphrase" (p. 246). If there were anything said or asserted in the metaphorical expression beyond what it literally states, then it would be just the sort of thing that does submit to paraphrase. As it is, however, what it provides us with beyond the literal is not anything propositional at all.

> It should make us suspect the theory that it is so hard to decide, even in the case of the simplest metaphors, exactly what the content is supposed to be. The reason it is often so hard to decide is, I think, that we imagine there is a content to be captured when all the while we are in fact focusing on what the metaphor makes us notice. If what the metaphor makes us notice were

> finite in scope and propositional in nature, this would not in itself make trouble; we would simply project the content the metaphor brought to mind on to the metaphor. But in fact there is no limit to what a metaphor calls to our attention, and much of what we are caused to notice is not propositional in character. (Davidson, 1979, pp. 262–263)

In this passage, however, Davidson seems to allow that reference to a kind of meaning distinct from the literal would be legitimate if what the utterance got across were "finite in scope and propositional in nature." Then, presumably, we could get a handle on paraphrase, and we could start talking about what was said and what was meant. It was said earlier that it is difficult to settle how much Davidson wants to rest on these considerations; and the reason for this is that, although they run through the entire paper, he also freely admits that it may just as well be said of literal language that its interpretation is not determined by rules (Davidson, 1979, p. 245), and that what it gets across to the audience is often not "finite in scope" (p. 263, n. 17). And, certainly, no theorist wants to deny meaning or cognitive content there. (As far as putting into other words goes, we might also ask how one would paraphrase many perfectly literal statements, such as 'The sky is blue' or 'I can hear you now.') Nor should simple vagueness or indeterminacy in interpretation be thought of as crucial to the issue of meaning, for vagueness itself can be something fixed by the dictionary meaning of a term. For instance, 'house' is a word with a perfectly straightforward meaning, but which allows for a zone of indeterminacy as to just which structures shall count as houses (for discussion of different conceptions of vagueness, see Chapter 28, SORITES.)

If there is to be a genuine case against metaphorical meaning along these lines, then, it seems that we should see the crux of the issue not as concerning indefiniteness as such, but as concerning the question of whether we may speak of propositional content in connection with metaphor. It is certainly true, as Davidson says, that "much of what we are caused to notice is not propositional in character"; but it does not follow from this that the figurative process does not communicate anything that is propositional as well. It seems clear that part of what traditionally raises philosophers' suspicions about the propositional content of poetic metaphor is not the assumption of an incompatibility of content with indeterminacy, but rather the connection of this aspect of the figurative dimension of metaphor with ideas of ineffability, or the essential inability to capture this dimension in words other than those of the specific metaphor itself. When a content or a thought is held to be ineffable, and not simply indeterminate, it is felt that, although one may have a perfectly definite content in mind, it cannot be fully expressed in words. (In fact, in various contexts the sense of indescribability is a response to the highly determinate character, the utter specificity, of what one has in mind.) Or, as in the case of certain poetic metaphors, it may be felt that the idea may be verbally expressed, but only in these very words; or only indirectly expressed, or incompletely hinted at. This sense is certainly something different from simple vagueness, and does raise different questions for the idea that what live metaphor does is communicate some special propositional content. If we agree with Davidson that this problem removes any justification for looking for propositions expressed by metaphorical utterances, then we may still say all we like about the various non-cognitive effects of such utterances, but we will no longer be able to describe metaphor in terms of communication, meaning, or content.

However, ineffability of the sort under consideration here concerns a claim about the specifically linguistic representation of a thought, and does not immediately place something outside the bounds of the propositional unless we have already agreed that a proposition is something essentially linguistic or sentential. Only then will it seem obvious that accepting

an equivalent prose paraphrase is necessary for any part of the metaphor to count as a propositional content. Davidson could be correct when he says, "A picture is not worth a thousand words, or any other number. Words are the wrong currency to exchange for a picture" (Davidson, 1979, p. 263), but it wouldn't follow from this that a picture cannot itself be a representation of a propositional content. For on one standard view of what propositions are, they are "functions from possible worlds into truth values" (Stalnaker, 1972); and on such an account – whether or not it takes reference to 'possible worlds' at face value (see Chapter 31, MODALITY, §3) – pictures, maps, memories, or anything else that represents the world as being a particular way can qualify as propositional representations. (We may thus, in Stalnaker's words, "abstract the study of propositions from the study of language.") If one takes this wider view of what a proposition is, there may be less resistance to considering the possibility of someone with a particular cognitive content in mind, but who is either unwilling or unable to accept an equivalent of it in prosaic language. We could accept Davidson's point about translation into another representational medium, without accepting the identification of the propositional with the sentential.

In fact, for purposes of this discussion, there would be little to complain of in the restriction of propositional content to the meaning of sentences, so long as we kept in mind the various different ways in which the content of a sentence may be indicated and determined in a context, including making essential reference to something extra-linguistic. We may note that many belief reports are only partially verbal reports, with the essential content of the belief being indicated in some other way:

> Many of our beliefs have the form: 'The color of her hair is –,' or 'The song he was singing went –,' where the blanks are filled with images, sensory impressions, or what have you, but certainly not words. If we cannot even say it with words but have to paint it or sing it, we certainly cannot believe it with words. (Kaplan, 1971, p. 142)

Thus, to bring us a little closer to the case of metaphor, a sentence like 'He said it in this voice just like Akim Tamiroff' is in perfectly good order, and expresses a genuine thought. But, of course, it will not communicate much to someone who has never heard of Akim Tamiroff. This particular person and the experience of his voice are essential to the content of the proposition. To someone who has never heard this voice, the speaker may quite straightforwardly be unable to communicate what she means. And it is all too easy to imagine being unable to provide any descriptive equivalent, and that no substitute expression will capture what you want to say. Yet it would certainly be wrong to conclude from this that the speaker has not said or meant anything. (For a defense of the idea of metaphorical meaning, which makes extensive use of the comparison with demonstratives, see Stern, 1985 and 1991. See also Chapter 38, THE SEMANTICS OF PRAGMATICS AND INDEXICALS.)

Similarly, with a metaphorical expression like the well-worn example of Juliet and the sun, reference to the sun is essential to the determination of the content of what Romeo has in mind, and his reluctance to accept any prose paraphrase as capturing all that he means is not itself any reason to deny that he does have something in mind which he is seeking to express in words. Nor would it be right to say that although he does have some content in mind (since we reject the simple sentential view of cognitive content), there must be some confusion involved in trying to express it verbally. Hence, to qualify a concession made earlier for the sake of argument, words may sometimes be the wrong medium of exchange for a picture, but it depends on what we are expecting the words to do. We may not be

entirely satisfied with any descriptive translation of what was said in either the Akim Tamiroff or the Juliet case, but even so it won't follow that "the attempt to give literal expression to the content of the metaphor is simply misguided" (Davidson, 1979, p. 263). As with any attempt to put one's thoughts and feelings into words, it may matter a great deal to try to go as far as one can in this direction. If we can't make sense of this kind of effort at descriptive and expressive fidelity, then we can't make sense of the kind of struggle that goes into the composition of poetic metaphor in the first place, let alone more everyday efforts to put the non-verbal world of experience into words.

(These considerations relate to the debate since Aristotle over whether metaphor and simile are essentially different figures. Fogelin, 1988, and Dammann, 1977–1978, both defend a 'comparativist' view of metaphor, and insist on the distinction between figurative and non-figurative comparisons.)

5 Metaphor and Communication

The discussion thus far has suggested that neither vagueness nor the indeterminacy of the interpretation of metaphor provide good reasons for denying that metaphor has a cognitive content beyond the literal. And, further, even if the difficulties or inadequacies of paraphrase are attributed to a degree of 'ineffability' (and not just indeterminacy) in what is seeking expression, this need not mean that we are not dealing with a genuine propositional content. Naturally, these considerations do not by themselves constitute an account of figurative meaning. Many difficulties remain in making sense of meaning and content as applied to metaphor, and these include various problems that were left hanging in the earlier discussion. For instance, we still need to describe a sense of 'meaning' as applied to metaphor which doesn't reduce to ordinary ambiguity or the expansion of application of a term. We have not yet explained the special dependence of the figurative meaning on the literal meaning, a dependence that has so far only been described metaphorically as the literal meaning's still remaining 'alive' in the figurative context (that is, unlike a code). And very little has been said so far to relate the sense of 'meaning' at stake here to more familiar uses of the term in ordinary speech and in more formal uses in the philosophy of language.

But lest we lose heart at the prospect of these and other problems for explicating the sense of figurative 'meaning,' it would be worthwhile to remind ourselves of how serious the consequences would be of endorsing a fully non-cognitive account of metaphor of the sort Davidson and others have recommended. (The most comprehensive defense of the rejection of metaphorical meaning is David Cooper's 1986 book, *Metaphor*, especially ch. 2.) It is important to Davidson's view that it be seen not as 'no more than an insistence on restraint in using the word "meaning"', but rather as a rejection of the idea that "associated with a metaphor is a definite cognitive content that its author wishes to convey and that the interpreter must grasp if he is to get the message" (Davidson, 1979, p. 262). So, to begin with, any such theory is burdened with the same problems as is non-cognitivism elsewhere in philosophy (see Chapter 31, MODALITY, §4, and Chapter 20, REALISM AND ITS OPPOSITIONS, §4). There will be nothing for understanding or misunderstanding a metaphorical utterance to consist in, nothing to the idea of getting it right or getting it wrong when we construe what the 'figurative meaning' might be. Related to this are non-cognitivism's familiar problems with making sense of the apparent facts of agreement and disagreement in the domain in question; for the rejection of any distinctive content to a metaphorical utterance obscures

understanding of what, for instance, the negation or denial of such an utterance can mean, and such a denial will, in the ordinary case, be a denial of the utterance taken figuratively. If there is nothing to the idea of a distinctive figurative content, then there's nothing for the speaker's audience to be agreeing with or dissenting from, except for the statement taken literally, and agreement or disagreement with that statement is not to the point. Further, if the figurative dimension involves no difference in meaning, but instead simply 'nudges us into noticing some resemblance,' then it's hard to say what differences of meaning we can point to between 'Juliet is the sun,' 'Imagine Juliet as the sun,' or even 'Juliet is not (or is no longer) the sun.' All three sentences succeed in linking the two ideas, but they hardly say the same thing. We might compare such problems with the difficulty for moral non-cognitivism in providing an account of the functioning of moral terms in conditional contexts, when some moral predicate is not being asserted, but is used in the context of reasoning and argument. (For more on these and other criticisms of non-cognitivism as applied to metaphor, see Bergmann, 1982; Elgin, 1983; Kittay, 1987; and Tirrell, 1989, as well as the papers mentioned previously in connection with Davidson.)

The cost of the denial of any specifically metaphorical content, then, seems rather steep, and the case for the banishment of metaphor from the realm of meaning to that of 'use' or the brute effects of utterance seems flawed. It is true that there are many things done in speech that do not involve communication and meaning, but are more purely causal effects of utterance (although, of course, communication is causal in its own way too). We are told, for instance, that metaphor gets us to notice things (similarities or incongruities, or whatever). And it is in terms of such particularities of use that Davidson compares metaphor with the use of language to lie, persuade, or complain. However, a few things must be noted about this comparison. First, it is not at all clear that metaphor is a 'use' of language in this sense at all. It would not, for instance, serve as any explanation why someone said what she did simply to say she was speaking metaphorically. Further, lying or complaining can count as "belong[ing] exclusively to the domain of use" (Davidson, 1979, p. 247) rather than meaning, precisely because whether one says 'It's raining out' to lie or to complain does not affect the truth-conditions of the utterance. But, of course, whether the truth-conditions of an utterance may indeed differ on a metaphorical interpretation is just the point at issue, and cannot be begged at this point.

And when we do speak of metaphor as producing various effects, it is important to note in the context of this discussion that it accomplishes these effects in a quite particular manner, one which involves a relationship between a speaker and an audience, and an interconnected network of beliefs about intentions, expectations, and desires; in short, just the sort of situation that Paul Grice and others have argued is what differentiates a situation of meaning and communication from the other various ways in which beliefs may be acquired (see Chapter 3, INTENTION AND CONVENTION IN THE THEORY OF MEANING, especially §5). As Davidson notes, plenty of things, like a bump on the head, can get one to notice or appreciate something, even something profound, and we don't think of all such cases as involving anything like meaning or communication. However, metaphorical speech counts as genuinely communicative (of a content beyond the literal) because, among other things, the figurative interpretation of the utterance is guided by assumptions about the beliefs and intentions of the speaker, intentions which, among other things, satisfy the Gricean formula (intending that the intention be recognized by means of this very utterance). And because we are in this way dependent on beliefs about the speaker's beliefs there is a purchase on the ideas of understanding and misunderstanding what was meant, none of which applies when some non-intentional causal phenomenon succeeds in making one appreciate some fact.

The dependence of the hearer on beliefs about the speaker has several layers. To take the utterance as metaphorical in the first place requires assumptions about the beliefs and intentions of the speaker. Then, even the non-assertoric dimensions of the reception of metaphor (framing one thing in terms of another, the clash of images, and so on) are dependent on what we take the relevant dimensions of the comparison or contrast to be. Lacking any idea of the intended salient features of, say, music, food, and love, we would fail to have so much as a non-assertoric comparison or contrast of these elements, let alone a metaphorical assertion. And finally, the interpretation of the utterance involves assumptions about the speaker's beliefs about the various elements, including her beliefs about their salience to the audience, and about what, if any, particular attitude toward these things is expressed by the metaphor. None of these dependencies obtain with respect to all the other various ways in which the phenomena of the world can cause one to be struck by something or other, and that is the primary reason why we speak of communication, understanding, and misunderstanding in the one set of cases and not the other.

6 Pragmatics and Speaker's Meaning

These and other considerations have led many writers on the subject to identify the meaning of a metaphorical utterance with what is called the speaker's meaning, in contrast with the semantic meaning, of the sentence. The latter notion concerns the meaning of a sentence in a given language, and is standardly understood to be a function of either its truth-conditions or its *assertability conditions*, assuming a certain context. Speaker's meaning, by contrast, concerns what a speaker on an occasion may employ a sentence to imply or communicate, a content that may diverge more or less widely from the content assigned to the sentence by the language. Hence, in ironic speech, for example, a speaker may utter the words 'That was a brilliant thing to say,' in order to communicate something quite different from what the sentence-type means in English. (The example of irony shows the usefulness of separating the issue of 'meaning-change' – which patently does not apply to the words of an ironic utterance – from the issues of communication and cognitivity.)

Speaker-meaning will typically be an instance of what Grice has called 'conversational *implicature*.' Very briefly, Grice sees linguistic behavior as guided by a general Cooperative Principle, which divides into various more particular maxims, such as 'Do not say what you believe to be false,' or 'Be relevant,' and which speakers expect to be obeyed in conversational exchange. Naturally, any such maxim may fail to be observed on a given occasion (people do tell lies, for instance). But what is important to Grice's story is the different ways in which a maxim may not be observed. For it may be that it is not followed either through sheer carelessness, or because the speaker is 'opting out' of the conversational exchange altogether, or, most importantly here, the speaker may 'flout' a maxim. In such a case the speaker makes it manifestly clear that, on one level at least, she is intentionally violating some maxim. In the above example of speaking ironically, the speaker takes it to be clear to the audience that she does not think what was just said was brilliant, and yet here she is, uttering a sentence with that very meaning. Hence she is flouting one of Grice's 'Maxims of Quality' ('Do not say what you believe to be false'). At this point it is up to the hearer to construe what the point of the utterance could be, and what other proposition(s) may be intended. The general assumption of the Cooperative Principle is retained, but the hearer now looks for what proposition may be implicated by this utterance. Thus conversational

implicature is a means of communicating something different from the literal, semantic meaning of the sentence uttered.

Taking this general approach, John Searle takes the general formula for metaphor to be: A speaker utters a sentence with (semantic) meaning 'S is P,' but does so in order to convey (or 'implicate') a different proposition, namely 'S is R.' In Searle's example (1979), someone says 'X is a block of ice' in order to convey the very different proposition that X is emotionally unresponsive and so forth. In most cases it will be the manifest or categorical falsity of the sentence taken literally that cues the audience to interpret the utterance as implicating something metaphorically. The main questions for which Searle takes a theory of metaphor to be responsible are, then, how an utterance is recognized as metaphorical (rather than ironic, say), and what principles the hearer employs to compute the speaker's meaning from the meaning of the sentence uttered, combined with the context of utterance.

An account of this general form may, then, offer us a sense of 'meaning' as applied to metaphor, which does not entail that a linguistic entity as such somehow contains within itself a metaphorical as well as a literal (semantic) meaning, but one which is nonetheless a sense of 'meaning' which bears some important relation to meaning in the strictly semantic sense. It also offers some understanding of the special dependence of the figurative on the literal, in that it is only through comprehension of the literal meaning of the statement that the hearer may reach the secondary meaning 'implicated' by the utterance. And the principles that guide this interpretation will involve appeal to features of resemblance, contrast, context, and emotional attitudes toward the subject that make the relation between literal and figurative meaning very much unlike the relation between a word and its substitution in some code.

In addition, such a view need not subsume 'figurative meaning' under the categories of simple ambiguity and ordinary expansion of meaning. Gricean implicature involves there being some point to the speaker's application of this phrase, with this literal meaning, in this context in order to convey something quite different. Common ambiguity (such as, say, homonymy) does not involve any such point or communicative intent. Nor need there be any such point in the case of the ordinary expansion of the application of a term. In some cases there may be some such point to the expanding, but often there will not be. When there is some point to the extension (as in, for example, the extending of 'mouth' to parts of bottles and rivers) the motivation may simply concern some perceived similarity between the various things now referred to by the same term (Davidson's example). In those cases the theorist of 'speaker-meaning' will indeed need to distinguish the point of metaphorical speech from that of ordinary expansion of the application of a term without any communicative point; otherwise he fails to distinguish figurative meaning from some forms of ordinary ambiguity. On the other hand, one may not want to distinguish the two cases too sharply, because metaphor is, after all, one of the vehicles of the normal extending of the application of words. Sometimes when metaphors die, their death involves the alteration of the ordinary dictionary meaning of a term, as in the case of 'mouth.' This phenomenon is, in fact, a further problem for any view that denies any distinct cognitive content to live metaphor. For it is clear that part of the meaning of the word 'mouth' is different now from what it was prior to the development of the metaphor, and yet we would not be able to say where the difference in meaning came from if the metaphor had no content aside from the (old) literal one when the metaphor was alive. By the same token, this would also, of course, oblige the theorist of speaker-meaning, for whom the distinction between it and semantic meaning is crucial, to say something about the diachronic story of how speaker-meaning becomes 'regularized' over time and merges into an altered semantic meaning of the term.

There are thus some promising features of this general approach, but its application and explanatory power also seem to have some significant limitations. First of all, it's not clear, on Searle's version of the theory anyway, that much has been said to elucidate the specifically figurative dimension of metaphor. If what one is doing in speaking metaphorically is saying (or making-as-if-to-say) 'S is P' in order to convey the different proposition 'S is R,' then it is hard to see how anything in the way of special insight or enhanced apprehension of the subject is achieved in this way. And it doesn't seem enough to make up for the flat quality of the analysis to add, as Searle does, that the speaker may intend "an indefinite range of meanings, S is R1, S is R2, etc." (Searle, 1979, p. 115). No degree of indefiniteness alone will add up to power or insightfulness. (And if one is skeptical of the claims made for insight and metaphor, the criticism would remain that even the appearance of power or insight – which surely does require explaining – seems to find no place in this account.) Related to this is the problem, common to many accounts that want to emphasize the cognitive aspect of metaphors and their role in assertion, that the account seems derived from the consideration of only the dead and dying among metaphors. And even this class is normally restricted to examples of the familiar subject–predicate form; whereas, clearly, a major part of the theoretical interest in metaphor concerns the desire to understand what is deeply right or expressive or illuminating in such occurrences of live metaphor as in the dense figurative networks of literature, which need not involve any phrases in subject–predicate form, or be part of any statement of fact (either real or pretended). (By comparison, we might ask here how a caricature or a gesture can be 'right,' expressive, or illuminating.)

A further way in which the 'live' quality of live metaphor seems to escape this analysis is in the account of how interpretation proceeds and what the derived meaning consists in. For if the meaning of a metaphorical utterance is the speaker's meaning, and the latter is a function of the intentions of the speaker in making the utterance, then the meaning of metaphor in general will be confined to the intentions of the speaker. Interpretation of the metaphor, then, will be a matter of the recovery of the intentions of the speaker. This may do well enough for instances of well-worn metaphor with little suggestive power left, but it gives the wrong picture of the interpretation of live metaphor. As Cooper says, in criticism of the 'speaker's meaning' view, "even a quite definite speaker-intention does not finally determine the meaning of a metaphor" (Cooper, 1986, p. 73). It is consistent with this criticism to insist, as claimed earlier here, that the interpreter of a metaphor is dependent on various assumptions about the beliefs and intentions of the speaker, and that this is required even to achieve a sense of what sort of figurative comparison is relevant. For it does not follow from this claim that the interpretation of metaphor is restricted to the recovery of the speaker's intentions. The interpreter may need to presume various things about the beliefs of the speaker for the metaphor to succeed in picturing one thing in terms of another; but once that perspective has been adopted, the interpretation of the light it sheds on its subject may outrun anything the speaker is thought explicitly to have had in mind. And on the other hand, from the point of view of the speaker, the restriction to speaker-meaning seems inadequate, in that it construes metaphor as a kind of shorthand or mnemonic device for a given set of beliefs that she wishes to convey. What such a picture leaves out of consideration is the role of metaphor in thought, the fact that the composition of live metaphor is undertaken in the expectation that it will lead one's thoughts about the subject in a certain direction: that it will be productive of new thought about it, and is not just a convenient summing-up of beliefs one already has.

(The comparison of metaphor with models in science has inspired work on metaphor as a vehicle, and not just a repository, of thought. On this, see various papers in Ortony, 1979. This general point, however, is not restricted to the case where a metaphor functions as a kind of explanatory model, but applies as well to the composition of metaphor in everyday and poetic cases, where it is not functioning as a model for explanation. This aspect of 'metaphorical thought' has received considerably less attention in recent philosophy.)

7 Metaphor, Rhetoric, and Relevance

We have arrived, then, at a familiar point of tension for theories of metaphor. On the one hand, there is the desire (widespread, but not universal) to see metaphor as a cognitive phenomenon and hence as having a describable role in such activities as assertion, communication, and reasoning. But on the other hand, theories of metaphor that seek to defend and define this cognitive role often end up obscuring the very features of metaphor that make it an object of theoretical interest in the first place: its figurative power; the role of metaphor in expressing or producing insight of some kind; or the special open-ended role of the interpretation of live metaphor. It is no surprise, then, that 'non-cognitive' theorists like Davidson emphasize the difference between live and dead metaphors, whereas 'cognitive' theorists often either downplay the distinction or deal with examples of metaphor that might as well be dead.

To make progress from here, it may be useful to reorient our approach to the whole phenomenon, to consider cognition and communication outside the context of strictly linguistic activity, and to begin investigating them from this broader perspective prior to explicit theorizing about the case of metaphor. That is, instead of taking the determinate proposition expressible in a simple sentence as our paradigm, and then asking how closely metaphor may or may not approach this model, we might begin with communicative situations that are non-verbal, indefinite, and unstructured, and ask where we might locate metaphorical speech on a continuum of cases from there to explicit, literal speech. This is more or less the approach taken by Dan Sperber and Deirdre Wilson in their 1986 book, *Relevance*, and in subsequent publications on rhetoric and communication. They see linguistic communication as but one variety of the larger class of what they call 'ostensive–inferential communication,' which encompasses "behavior which makes manifest an intention to make something manifest" (Sperber and Wilson, 1986, p. 49). (Their account has obvious points of contact with Grice's work, as well as important differences, and these are discussed in the book.) The breadth of the category of communication they employ, and the distance from the sentential paradigm, can be seen from one of their first examples of ostension, many of whose features have come up for discussion in the case of metaphor. Two people are newly arrived at the seaside, and one of them opens the window of their room and inhales appreciatively and 'ostensively,' that is, in a manner addressed to the other person. This person thus has his attention drawn to an indefinite host of impressions of such things as the air, the sea, and memories of previous holidays.

> [Although] he is reasonably safe in assuming that she must have intended him to notice at least some of them, he is unlikely to be able to pin her intentions down any further. Is there any reason to assume that her intentions were more specific? Is there a plausible answer, in the form of an explicit linguistic paraphrase, to the question, what does she mean? Could she have achieved the same communicative effect by speaking? Clearly not. (Sperber and Wilson, 1986, pp. 55–56)

If this sort of situation is accepted as an example of communication, we can see how many of the features of metaphor which are thought to stand in the way of any cognitive account find a natural place here; and the case of explicit, literal, verbal communication looks more like the special case. That is, the way may be open to see some types of verbal communication (such as, for example, figurative language) as sharing many of the features of this non-verbal example. Thus we could see metaphorical speech as involving dependence on beliefs about the speaker's intentions, but not restricted in its interpretation to the recovery of those intentions. We could speak of a content that is communicated, but which is to a significant degree indeterminate, resistant to paraphrase, and open to the elaborative interpretation of the hearer. And, since the account does not assume literalness as a norm, we could avoid the implication of a generally Gricean approach that speaking figuratively, for all its utter pervasiveness in everyday speech, must involve transgression of some sort, or the violation of linguistic rules. Or, to quote Sperber and Wilson (1986, p. 200), "[T]here is no connection between conveying an implicature and violating a pragmatic principle or maxim." (See also Cooper, 1986, on the 'perversity' objection to speaker-meaning theories. It should be noted that the rejection of the normative presumption of literalness does not entail the rejection of the previously described dependence of the figurative on the literal, that is, the idea that knowledge of the literal semantic meanings of the words involved is necessary for the composition or comprehension of metaphor.)

Here we can do no more than indicate a few of the main themes of their approach which relate to the case of figurative language. Sperber and Wilson see implicatures as being conveyed in speech not through a presumption of either literality or obedience to conversational maxims, but through the guarantee of relevance which, they claim, any act of ostensive communication carries with it. Such acts will lie on a continuum of cases from communication of an impression to coded information, from showing to saying. In fact, it is internal to this approach that various dimensions of assessment, normally construed categorically, will be such as to admit of differences of degree: literality and figurativeness, evocativeness, susceptibility to paraphrase, and degree-of-intendedness.

Relevance, as defined by them, concerns the value of information gained, in light of the cognitive 'cost' to the hearer of assimilating that information. (As the quoted example indicates, however, 'information' is a suitably broad notion here too.) The guarantee of relevance may go unfulfilled, of course, but it is different from a maxim that one either seeks to conform to or not. Relevance is guaranteed in the sense that any act of ostensive communication involves a claim on the attention of another person, and any such claim itself communicates the presumption that this attention is somehow worth the effort. Implicatures themselves may be weak or strong, far to seek or immediately obvious, and are related to each other in various ways. In this way, we may begin to have at least a useful description of the functioning of live or poetic metaphor, where the effort at interpretation generates a penumbra of stronger and weaker implications which in turn lead to others, more or less remote from the immediate inferential consequences of the utterance, but which are pursued in so far as the presumption of relevance is rewarded. Dead metaphors will be those with a relatively small network of implications, immediately comprehended at small cost. Along these lines, then, we may begin to be able to say a few things about what the figurative power of poetic metaphor consists in, and what claims can be made for it both as productive and as expressive of insight of various kinds (including, for instance, marking the difference between the 'live' or fully-felt appreciation of some fact, and its merely 'intellectual' apprehension).

* * *

A final note. The alternatives to non-cognitivism discussed here have been drawn from theories of conversation, or the pragmatics of language, rather than from semantic theories for natural languages. However, the semantic/pragmatic distinction in philosophy of language is itself a complex matter and a subject of controversy (see Chapter 6, PRAGMATICS). Thus, mention should be made of recent 'cognitive' accounts which explicitly challenge the assignment of figurative meaning exclusively to either one level of analysis or the other. So, for instance, Kittay (1987) describes her 'semantic field' theory of metaphor as one that moves between semantic and pragmatic accounts. And the work of Stern mentioned earlier belongs to a broadly semantic account, but finds the analysis of both metaphor and demonstratives to require "a notion of meaning one level more abstract than truth conditions" (Stern, 1991, p. 40). In these as well as other ways, discussed previously, we can see the theory of figurative language prompting the rethinking of some of the basic concepts in the philosophy of language generally.

ANDREW MCGONIGAL

1 Metaphor, Meaning, and Language: Positive Developments

A good theory of metaphor would tell us about the relationship between metaphor and language. In particular, it might help us address the following kinds of foundational questions:

Distinctness: Do metaphors linguistically express representational contents distinct from those that a literal interpretation would assign?
Distinctiveness: Does effective linguistic metaphor typically bring off something which is hard to achieve by literal means?
Dispensability: If we were unable to think and talk metaphorically, would we thereby be significantly cognitively or practically impoverished?
Demands: What kinds of theoretical constraints and explanatory challenges should a satisfying account of linguistic metaphor meet? Which developed account best meets those demands?

There is still no consensus as to how questions like these are best answered. But we are gradually getting clearer on the types of considerations that count for and against affirmative answers in each case. For example, most contemporary theorists of metaphor accept the following explanatory tasks.

a. Address the Error-Theoretic Challenge

Do metaphorical utterances linguistically express metaphorical meanings? Realist semantic theorists say yes: the metaphor *semantically expresses* some distinct metaphorical content. Realist pragmatic theorists say yes: the metaphor maker *pragmatically conveys* some such content. Anti-realist error theorists say no: the metaphorical utterance is at most linguistically related to a literal meaning, if to any. Other representational contents might be relevant to the metaphor – for example, as specifying its point, purpose, or significance – but not any old relation to a propositional content is a *linguistic* relation.

Donald Davidson (1979) gave the simplest and most influential argument for error theory:

(i) we don't need to appeal to metaphorical meanings to explain how linguistic metaphors are made and aptly interpreted, and
(ii) it isn't clear that, as standardly construed, they even *could* adequately explain those practices, so
(iii) we thus have no good theoretical reason to believe in them.

Error theory continues to attract defenders and adherents (see, e.g., Reimer, 2001; Lepore and Stone, 2010; McGonigal, 2008). Even their realist opponents, however, recognize the need to address the detail of Davidson's arguments, and to accommodate the insights of his position.

b. Respect the Active Role of Literal Terms and Context

Davidson stressed two key structural features of metaphor. First, the sense of literal terms plays an active shaping role in securing proper uptake of the metaphor. Standardly, someone who is in a position to fully understand

> A hungry sound came across the breeze,
> So I gave the walls a talking

draws upon their knowledge of the literal semantic contribution of the word "hungry." Second, the interpretation of metaphorical utterance is highly context dependent. When Stevens tells us that poetry is a pheasant disappearing in the brush, or Plath tells us that a pheasant is a little cornucopia, informed appreciation of those metaphorical utterances requires sensitivity to the details of the local context in which they are offered up for interpretation.

Realists about metaphorical meaning have attempted to accommodate these insights. Contextualists point out that standard treatments of many features of literal language – paradigmatically, the semantics of indexicals and demonstratives – make essential appeal to contextual features of token utterances. Different forms of contextualism about metaphor stress appeal to different models of contextual interaction. In one of the most detailed and developed accounts, Joseph Stern draws upon elements of Kaplan's semantic treatment of demonstratives. He argues that communication through linguistic metaphor involves tacit knowledge of a Kaplanian *character*; a rule that determines, for each context C, the content of the metaphor in C. Using *Mthat [E]* to lexically represent the metaphorical

interpretation of some literal expression E, Stern's view is that (i) *Mthat [E]* serves to determine different metaphorical meanings in different contexts (ii) in a manner which is systematically sensitive to the presuppositions of cooperative conversational participants in those contexts. In this way, his theory aims to (iii) account for the active role of the literal meaning of E in helping fix the interpretation of metaphor in context, while also (iv) allowing metaphorical meaning to be highly sensitive to features of context. (Leezenberg, 2001; Recanati, 2004; Carston, 2002; and Bezuidenhout, 2001, appeal to alternative features of context-dependent language.)

Contemporary pragmatic theorists in contrast (including Camp, 2006a; Denham, 2000) locate the active role of literal sense in the meaning of the sentence uttered, rather than the speaker-meaning thereby conveyed. Fine-grained sensitivity to context enters into the story of how that implicit speaker-meaning is recoverable by the interpreter. Quite how this is possible is a pressing issue: see Sperber and Wilson (1995) for criticisms of the standard Gricean account.

c. Integrate the Account with Broader Theoretical Consensus about Linguistic Communication

An influential view of linguistics presents it as

(a) appealing to a small set of sparse, distinctive properties and relations (*X is the semantic value of W*; *Maxim M governs cooperative communication between S and L*) in
(b) offering explanations of projectible, systematic, counterfactual-supporting linguistic regularities (*compositionality*; *systematicity*; *productivity*; *communication*; *presupposition*).

We thus have system and structure on both sides of the explanatory relation. Linguistic theory explains the comparative orderliness of the data in terms that appeal only to a small set of tightly characterized explanatory posits.

Contemporary realists and anti-realists typically agree that context matters to the interpretation of metaphor. They disagree about whether it does so in a way that is orderly enough to fall within the domain of linguistic explanation as described above. For example, error theorists often hold that the link between successful metaphor and its appropriate interpretation isn't systematic enough to be well explained by appeal to semantic or pragmatic rules. On this view, our ability to construct and interpret metaphor effectively doesn't consist in mastery of repeatable, projectible, distinctively linguistic mechanisms, such as Stern's *Mthat* operator, Gricean implicature, or pragmatic enrichment. The success and significance of individual metaphors might be explicable on a case-by-case basis, but not in virtue of our tacitly grasping linguistic rules that determine how an arbitrary metaphorical expression will be paired up with a distinctive, non-literal meaning.

Realists about metaphorical meaning generally concede that this point presents a serious challenge. They agree that the word "pheasant" in Stevens's metaphor does not take on a new stable metaphorical sense, apt for compositional redeployment across a wide range of linguistic contexts. But they stress the extent to which ordinary literal communication relies on mutual recognition of communicative intent, and skillful accommodation to a shared take on the world. These pragmatic abilities might be hard to systematize in a robustly

predictive way, and yet we might feel compelled to accept that some such set of capacities play an ineliminable role in linguistic communication. (See Chapter 6, PRAGMATICS, and Chapter 38, THE SEMANTICS AND PRAGMATICS OF INDEXICALS.)

This goes some way to answering the general meta-semantic question of how metaphorical meaning is possible at all. Since literal communication is actual, the capacities it requires must be actual: if those are in turn the core capacities drawn upon in metaphorical interpretation, then that's evidence that metaphors could at least in principle express meanings. However, this line of thought doesn't do much to help explain why metaphorical utterances are assigned the *particular* contents that the realist wants to attribute to them. Realists are sensitive to these concerns, and have tried to offer more detailed accounts of the mechanisms that generate interpretations of particular metaphorical utterances. Nevertheless, even the most developed of these typically accept that they do not have a fully satisfying response to the error-theoretic challenge from anti-systematicity.

d. Account for an Accepted, Detailed Range of Linguistic Phenomena

The most effective responses to the error theorist cite a range of linguistic data that is putatively best explained by the existence of metaphorical contents. For example, Stern has emphasized the behavior of metaphor embedded in tensed and modal constructions such as:

> "Greg has always been a failed attempt, a stuffed shirt, a shirt-shaped hole in the air."
> "Yeah, if Rolls Royce started building really terrible cars, he would be the Rolls Royce of people."

and the zeugmatic effect of verb phrase ellipsis in constructions such as

> "Achilles is the sun, and Juliet is too."

in motivating his realist semantic view of metaphorical meaning. Patterning of speech acts such as assertion, rejection, extrapolation, question and answer, provide another potential range of data (see, e.g., Bergmann, 1982). A variety of issues in lexical semantics also seem to cast light on the nature of metaphor. Michael Glanzberg (2007) has suggested that while lexical items such as nouns and verbs can be reinterpreted metaphorically, linguistic items being deployed in 'functional' categories such as quantifier expressions and tenses cannot. If true, then this *prima facie* surprising contrast between, say, "more than" and "larger than" seems to call out for explanation. More generally, Alison Denham (2000) has suggested that pragmatic realism about metaphorical meaning can help explain the role of metaphor in plugging certain lexical gaps.

e. Integrate Account with Psychological Data

The interaction between linguistics, psychology, and philosophy provides another rich seam of data. Peacocke (2009) argues that when we experience one thing metaphorically-as another our experience thereby has a distinctive kind of representational content. If this is correct, then good theory of metaphor should tell us how such metaphorical Thoughts are

related to linguistic utterances. Peacocke's own view is that the connection between metaphor and language is somewhat secondary and indirect:

> The second component of my account is a conception of metaphor as essentially non-linguistic, as something cognitive that can be present in many different types of mental state and event. Metaphor can enter thought; it can enter imagination; and it can enter perception. We can think of life as a journey; we can imagine an atom as consisting of a star and orbiting planets; we can perceive modern windmills in a wind farm as an army of warriors … We have metaphors in language only because we need a device for expressing these mental states whose content involves metaphor. Understanding a metaphor expressed in language involves thinking or imagining whose content is a metaphor. There would be no metaphorical language if there were no mental states whose contents involve metaphor. (Peacocke, 2009, p. 260)

Even if this understates the constructive meta-semantic role played by distinctively linguistic features such as rhyme, rhythm, literary allusion, linguistic echo, and cliché, a completed theory of metaphor surely ought to address the kinds of cognitive phenomena that Peacocke emphasizes.

Evidence from sub-personal psychological processing has also seemed apt to constrain theories of linguistic metaphor. For example, facts about the comparative processing speed of metaphorical and literal language have been thought to count against a pragmatic view (Camp, 2006b, gives a helpful overview). Again, if it is true that some autistic subjects who smoothly understand metaphor struggle to understand irony, but never vice versa, then this would seem to speak against simple Gricean treatments that treated the two cases analogously (Carston and Wearing, 2015).

2 Distinctiveness and Dispensability: For and Against

Elizabeth Camp (2006a) holds that (i) the employment of linguistic metaphor typically involves speakers meaning something different than what they say, (ii) such metaphorical utterances do not do anything distinctively different in kind from literal ones but nevertheless (iii) are essential for grasping certain important propositions. This combination of views can at first seem puzzling: how can the formulation and interpretation of metaphor fail to have distinctive linguistic results, and yet be indispensable for certain tasks? Camp's answer is that what metaphor users mean can be in some sense *expressed* in literal terms, but not *paraphrased*. Paraphrase requires more: provision of a specification of the content of the speaker's illocutionary intention in terms explicit enough that inability to grasp it would indicate some form of semantic incompetence. For Camp, effective selection and interpretation of metaphor is instrumentally essential for our coming to understand the proposition expressed, and so no such literal paraphrase is available.

We might wonder why paraphrase in this sense is what matters. James Grant (2010) has complained that Camp does not establish that metaphor is an essential route to the content of any cognitive or communicative acts. Suppose that Camp is right that

> (M1) When he finally walked out the door, I was left standing on the top of an icy mountain crag, with nothing around me but thin cold air, bare white cliffs, and a blindingly clear blue sky.

cannot be adequately paraphrased by some literal utterance of the form

> (P1) I felt an emotion which was like the way it would feel physically to stand on top of an icy mountain crag, with nothing around me but thin cold air, bare white cliffs, and a blindingly clear blue sky.

because such a specification would still 'rely at least implicitly on the original metaphor' and so fail the explicitness condition on paraphrase:

> if 'like' expresses a substantive relation which holds just in case a particular, contextually salient similarity holds between the two objects … then [P1] implicitly builds those similarities into its content. It may then succeed in capturing the speaker's intended content, but it arguably also fails to be fully explicit, in much the way that 'He's ready' fails to specify its implicit argument. (Camp, 2006a, p. 12)

Even if every such putative paraphrase failed, Grant objects, it is still left open that some of them express the relevant illocutionary content implicitly. And if they do so, then how can the deployment of *metaphor itself* be cognitively or communicatively essential? As Grant notes, communicating a metaphor's content implicitly is different from implicitly relying on a metaphor that communicates the same content. Why should we concern ourselves with unparaphrasability, as long we can systematically pair off every metaphor with a literal statement expressing the same representational content?

Grant presses a related objection against Steven Yablo's claim that some metaphors are 'representationally essential' – that is, that the best way to specify a given metaphorical meaning might involve redeployment of that very metaphor. For example, Yablo (1998) suggests

> It seems at least an open question, for example, whether the clouds we call angry are the ones that are literally F, for any F other than 'such that it would be natural and proper to regard them as angry if one were going to attribute emotions to clouds.'

Even though he thinks that adequately specifying the content of certain metaphors may require redeploying metaphor, Yablo does offer a meta-semantic account of how metaphors derive their content. This is a version of Kendall Walton's view of metaphor as a form of 'prop oriented make-believe' (Walton, 1993). On this view, when we use a metaphor, we represent a situation as having just those properties that would make our utterance appropriate in a certain game of make-believe, one that the metaphorical utterance itself invites or suggests. But Grant seeks to turn this Walton-style explanation against Yablo's claim that metaphorical contents cannot be adequately specified without metaphor. He argues as follows:

(i) Yablo thinks that we need metaphor to access the ensemble of worlds that comprise the metaphorical content of the metaphor S.
(ii) But we can use Yablo's own description of the mechanics of content-generation to pick out the relevant ensemble: namely, the worlds W that legitimate the pretense-worthiness of S.
(iii) That description is not itself metaphorical.
(iv) So *contra* Yablo, we do not need metaphor to access the ensemble of worlds that comprise the metaphorical content of the metaphor S.

This style of objection, however, doesn't seem to give due weight to the fact that the relevant account of paraphrase relates it to linguistic *understanding*. On Camp's view, saying that linguistic metaphors are contentful but unparaphrasable is denying that successful exercise of basic linguistic competence and rationality puts one in a position to understand them, to know what speakers mean by them. Additional psychological capacities are required, and it makes sense to wonder what they are, and how and when they are deployed. That's a different project than aiming to systematically assign suitably related, intensionally equivalent truth-conditions, but one that seems well motivated.

Consider an analogy from the philosophy of mind. Perhaps a judgment with the conceptual content I AM HUNGRY is true if and only if a hungry judger thereby *self-ascribes* the property of hunger. In that sense, the truth-conditions are the same whether we employ the first-person, or an unanalyzed concept of self-ascription. But that wouldn't show that first-person thought was cognitively dispensable. For all that the equivalence shows, being able to self-ascribe just consists in being able to ascribe properties to a particular object, oneself, thought of in first-personal terms. Noting the equivalence doesn't itself establish that our best theories of the mind could be properly expressed without the first-person. Nor does it show us where to look for an account of how creatures might become able to think first-personally, offer any explanation of the distinctive cognitive and epistemic properties of such thought, and so on. But those are surely interesting philosophical and psychological questions in their own right.

There are similar worries about Grant's argument against Yablo. What is it to 'access an ensemble of worlds'? For Grant's argument to go through, it had better be that we have accessed the metaphorical content in the relevant way when we have identified a uniquely specifying description of it. But that approach to grasp of content seems implausible in general. There is a good sense of access in which somebody with normal color vision has a way of accessing the colors of things that is unavailable to one who lacks it. But the latter subject can identify a uniquely specifying description of the relevant set of objects: namely, the set S of objects that the former subject's distinctively visual concept of blue correctly applies to. If cognitive access only required being able to find some way of uniquely specifying the set of possibilia that an expression was correlated with, then color vision would not be an explanatorily privileged way of accessing the colors of things. But there is a good sense in which the color-blind cannot access the colors of things, and so there is a good sense of cognitive access which requires more than unique specification of content.

If the above analogies are compelling, then settling the question of the indispensability of linguistic metaphor may require us to understand what is involved in thinking metaphorically. That second, broader project, however, may not be one that falls within the scope of philosophy of language as traditionally conceived.

Conditionals

ANTHONY S. GILLIES

1 Introduction: Conditional Information

I want very much that you have the information that the beer is gone. In fact, I want you to take action that requires it. (Let us also stipulate that that action is unavailable (insert your favorite constraint here: policy, prudence, politeness) if there is plenty of beer.) So I say something that gives voice to the state of affairs, beer-wise:

(1) The beer is gone.

I hope that you understand me and take that information on board and then do the right thing. But things won't work out if I'm mistaken about the facts, for then what I am trying to pass off as information isn't that and my hopes will go unfulfilled. Nutshell: successful information exchange depends on the way things are.

That's clear (enough) if the information I aim to get to you is plain (enough) and the linguistic vehicle simple (enough). Conditional information is a useful kind of information and it is no surprise that natural language has canonical ways of expressing it. That is what *if*s – conditionals – are for. So take a case of *conditional* information exchange where the information is less plain and the linguistic vehicle less simple:

(2) a. If Jimbo is here, then he bought this round.
b. If Jimbo is here, then he might buy this round.
c. If Jimbo were here, then he would buy this round.

The information at stake here is information about what is or might or might not be the case *if* Jimbo is here, and what would or wouldn't be the case *if* he had been. Nutshell: successful (conditional) information exchange depends on the way things are but also on the ways things are in various alternative scenarios (the way things are if such-and-such).

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

Not all conditional information is the same, and this is reflected in differences in conditionals. Take a so-called *Adams pair* (Adams, 1975):

(3) a. If Oswald didn't kill Kennedy, then someone else did.
b. If Oswald hadn't killed Kennedy, someone else would have.

The first conditional is an *indicative* conditional, saying what is the case if it turns out that Oswald *wasn't* involved. The second conditional is different. It has distinctive tense/aspect saying what *would have been* if, contrary to the facts, Oswald *hadn't* been involved. Such conditionals are *counterfactual* conditionals, but the name isn't a perfect fit.[1] The types of conditionals are genuinely different since (3a) and (3b) have the same antecedent and the same consequent, but one is true and the other false.

Two not-unrelated bundles of questions will occupy us here, regardless of the type of conditional we are considering. First bundle: What is that conditional information that is conventionally carried by various conditional constructions in natural language? Answering this will involve saying something about a conditional's dependence both on how things are and on how things might have been. It will also (but not invariably as we will see) involve saying when conditionals are true and when they are false. Second bundle: How do the various conditional constructions in natural language manage to carry that information? Answering this will involve saying something both about how a conditional's meaning arises from the parts of it and about how a conditional's meaning interacts with and contributes to the meaning of embedded and embedding environments. The bundles are in principle separable, but in practice often enough go hand in hand.[2] The first thing is all about saying what conditionals mean (what semantic values they have) and how things that mean those things are used in well-run conversations (what their pragmatic profiles are). The second thing is all about how *if* interacts with the rest of our language – how what specific conditionals mean is determined by the bits that make them up and about how conditional constructions contribute whatever-it-is they mean to embedding environments in which they occur as proper parts.

The aspiration is to at least see where some answers can be found.[3]

2 Preliminaries

Distinguish between (i) conditional sentences (indicative or counterfactual) of natural language and (ii) conditional connectives of some formal language that serves to represent the relevant conditional sentences. The aim is to associate an *if*-in-a-natural-language with an *if*-in-the-formal-language that then gets associated with its semantic value. We will assume that the role of the formal language can be adequately played by a simple propositional language with the usual sentential connectives ($\neg$, $\wedge$, $\vee$, $\supset$) plus a binary sentential connective (*if* $\cdot$)($\cdot$). Context will disambiguate which sort of conditional (*if* $\cdot$)($\cdot$) represents.[4] (When the time comes, we will also have use for modal operators of the usual sort like $\Box$ and $\Diamond$ and perhaps a few other things.) This two-step route to assigning meanings to conditionals isn't obligatory and is in principle dispensable (assuming that the mapping from natural language to the formal language (we won't fuss with this one) and then the mapping from the formal language to the universe of meanings (we will fuss with this one) are well behaved). But it does make for a clearer view of the landscape.

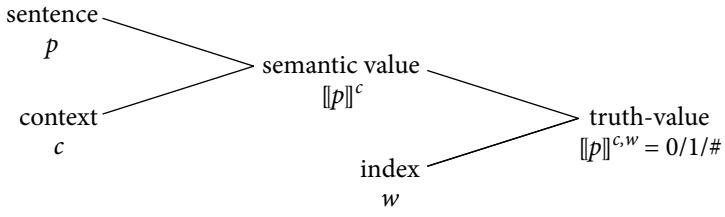

Figure 17.1 Variable but simple semantic values.

A (formal) language is only useful if it is interpreted. Whether or not truth-in-English has been achieved by an utterance of

(4) Jimbo has to be washing the dishes.

depends on the facts – how things actually are at the world where it is uttered. It also depends on the state of the conversation when it is uttered: for instance, whether what is being claimed is a claim about Jimbo's obligations or about what we know about his current activities. And it also depends on how things are in various other situations: for instance, whether at those relevant situations the prejacent *Jimbo is washing the dishes* is true. So truth-in-English is sensitive to both a context of utterance and an index of evaluation. One of the things we're after is a way of systematically saying when a sentence p is true in a context at a world.[5] So let's suppose that semantic values (whatever they are) determine truth-values at points of evaluation with respect to contexts. We will not need to say just what contexts are. It will be enough to carve out what role they play in the setup. Similarly, our indices will be worlds, but the most we need to know about them is that they are the kinds of things at which sentences are true or false.[6] The setup is summarized in Figure 17.1: a sentence p in a context c gets associated with a semantic value $[\![p]\!]^c$, which combines with an index w to deliver a truth-value (if the sentence has one) of the sentence at that world in that context, $[\![p]\!]\ c,w = 1$ or $[\![p]\!]\ c,w = 0$ or $[\![p]\!]\ c,w = \#$ (as the case might be). These aren't entirely innocent assumptions, but we can start here and suspend them when it suits us.

Theories of conditionals are constrained by the patterns of intuitive entailment they participate in. So what-intuitively-entails-what is important data and we want to explain its patterns as best we can. For conditionals this might tie what $(\mathit{if}\ \cdot)(\cdot)$ might mean very tightly to what we can and can't say about entailment. For instance, take the basic deduction theorem.

Deduction theorem $X, p \vDash q$ iff $X \vDash (\mathit{if}\ p)(q)$

Taking this as a constraint, what we say about $(\mathit{if}\ \cdot)(\cdot)$ impacts what we can say about $\vDash$ and vice versa. (This holds for various weakenings of the deduction theorem too, wherein the weakness lies in how the set of premises A and the premise p are combined.) The point is just that "entailment" is as much part of the theoretical machinery as is anything. So it's up for grabs whether what we say about *if*s bends to the will of entailment or whether what we say about entailment bends to the will of the *if*s. There is very little on stone tablets. That said, let's try to skirt issues about entailment when we can.

The simplest (and in a precise sense the weakest) conditional is the material conditional: $p \supset q$ is true iff either p is false or q is true. Accordingly, the simplest (and in a precise sense the weakest) theory of *if* takes it to simply be the material conditional.

Definition 1 (Horseshoe theory[7]). Conditionals are material conditionals:

$$[\![(\mathit{if}\ p)(q)]\!]\,c,w = 1 \text{ iff either } [\![p]\!]\,c,w = 0 \text{ or } [\![q]\!]\,c,w = 1.$$

This is, so far, neutral about whether the target conditionals are indicative or counterfactual. That matters and we will return to it.

In any case, this treats conditionals as truth-functional (and, by the way, context-invariant): the truth-value of a conditional at a world is entirely determined by the truth-value of its antecedent and consequent at that world. In fact, this is the only truth-functional option available for the conditional.

Fact 1. If $(\mathit{if}\ \cdot)(\cdot)$ is truth-functional then $(\mathit{if}\ \cdot)(\cdot) = \supset$.

Here's why. Suppose p = *The die came up six* and q = *the die came up even*. Our theory has to then render $(\mathit{if}\ p)(q)$ true no matter how the roll came out. So, in particular it's true if it came up six (antecedent true, consequent true), if it came up four (antecedent false, consequent true), and if it came up three (antecedent false, consequent false). The rub is that since by hypothesis $(\mathit{if}\ p)(q)$ only depends on the (actual) truth-values of p and q, any p and q with the same truth-values can be substituted in for them and the resulting conditional has to still be true. So: if a truth-functional conditional has a false antecedent or true consequent it is true. Now assume some conditional is false. It can only be because it has a true antecedent and false consequent. Given truth-functionality, this then holds for all conditionals. So: if a truth-functional conditional is false it has a true antecedent and false consequent.

As a theory of counterfactuals, this is an obvious non-starter. Conceptually, counterfactuals – the real deal ones with false antecedents – ask us to consider other, non-actual ways things might have been. But a truth-functional theory says that such considerings can't be relevant. The empirical coverage is also terrible. At least some counterfactuals with false antecedents are (contingently) true and thus worth arguing about. The material conditional rules that out.

(5) a. If Alex had come to the party, she would have arrived before 8.
b. If Alex had come to the party, she wouldn't have arrived before 8.

These conditionals cannot both be true, and speakers using them seemingly disagree. That is not what you'd expect if counterfactuals were horseshoes.

When it comes to indicative conditionals things are different: the horseshoe isn't widely adopted, but it is not without defenders. The main difficulty is that the material conditional is, from a logical point of view, weak. Taking indicatives to be horseshoes thus predicts that there are more entailments to conditionals than there seem to be. Among them: the paradoxes of material implication.

(6) a. Carl came alone.
??So: if Carl came with Lenny, neither came.
b. Billy got here first.
??So: if Alex got here before Billy, Billy got here first.

These don't strike as entailments even though the truth of either $\neg p$ or q at w secures the truth of $p \supset q$ at w.

The thing that has to be said is that while these are genuine entailments, there are pragmatic reasons – derived from how conditionals and surrounding sentences are reasonably and appropriately deployed in conversation – why they strike us as weird. For instance: the

conditional conclusions in (6) are weird because in each case a speaker in the position to assert the unconditional premise has no use for (and hence would mislead by using) the logically weaker conditional conclusion. So there is a clash between an implicature of the conclusion and the initial premise.[8]

Explaining away unwanted entailments by appeal to implicatures is tricky since this strategy has nothing to say about conditionals that occur unasserted in embedded environments. But conditionals occur in such environments and when they do the horseshoe theory makes some unhappy predictions. Negated indicatives are a case in point. The issue is that since material conditionals are so weak, their negations are correspondingly strong.

(7) It's not so that if the gardener didn't do it then the butler did.

I can be signed up for (7) without being signed up for the truth of *the gardener didn't do it*. After all, it might have been the driver. Maybe we need a pragmatic defense of our pragmatic defense. Perhaps what we have in (7) is a denial of a conditional rather than an assertion of a negated conditional, and so the negation is not a negation. I doubt it since the issue can be pushed where the negated conditional itself occurs embedded and thus unasserted and thus not open to this defense. For instance: the argument in (8) is a disaster but predicted to be an entailment by the horseshoe.

(8) If there is no god, then it is not the case that if I pray, my prayers will be answered.
I don't pray.
??So: there is a god.

Is there another pragmatic defense to save these pragmatic defenses of the earlier pragmatic defense? It's possible, but this rescue is quickly becoming a wheels-within-wheels situation.

3 Strict Conditionals

The material conditional is extreme in its myopia: only how things are at w matter to the truth of a material conditional at w. At the other end of the spectrum lie *strict conditionals*: these survey *all* possibilities. That is a quantificational claim and so, as with a lot of quantificational claims, this one may be restricted.[9] We will care about the *if*-relevant worlds in a context c. A strict conditional is a (restricted) universal quantifier, saying that all the *if*-relevant possibilities at which the antecedent is true are possibilities at which the consequent true. When the only job of contexts is to provide such worlds – as it is now – let's simply identify a context c with the selection function that delivers the *if* -relevant for each world w.

Definition 2 (Strict conditionals). Let $c(w)$ be the set of *if*-relevant worlds at w (in c).

$$[\![(\textit{if}\ p)(q)]\!]\,c,w = 1 \text{ iff if } v \in c(w) \text{ and } [\![\,p]\!]\,c,v = 1 \text{ then } [\![q]\!]\,c,v = 1.$$

This is equivalent to saying that $(\textit{if}\ p)(q)$ is true at w with respect to c iff the material conditional $p \supset q$ is true at every world in $c(w)$.

What does it take to be an *if*-relevant world? We haven't said (that's by design). Thus, depending on what we say about what it takes for a world to be an *if*-relevant world at w (that is, depending on what we say about the function c given an argument w), we get a different strict conditional.

Here are some possibilities (not exhaustive):

- For any w, only w ever matters (for every w: $c(w) = \{w\}$). The resulting strict conditional is the material conditional.
- For any w, all worlds (unrestricted!) always matter (for every w: $c(w) = W$). The resulting strict conditional is strict implication (true iff the antecedent entails the consequent).
- For any w, all worlds compatible with what is known in w matter (for every w: $c(w) = \{v$: if X is known at w then $v \in X\}$). The resulting strict conditional is a sort of epistemic strict conditional.
- For any w, all worlds similar to w to fixed degree d matter (for every w: $c(w) = \{v : v$ is similar to w to at least degree $d\}$). The resulting strict conditional is a sort of similarity-based strict conditional.

Notice that for each such $c(w)$ there is a corresponding (restricted) necessity operator $\Box_{c(w)}$ and a strict conditional $(if\ p)(q)$ with respect to $c(w)$ amounts to claiming that the corresponding material conditional $p \supset q$ is $\Box_{c(w)}$-necessary. The strictness of two strict conditionals can be compared: if the set of *if*-relevant worlds (at a world) for one strict conditional is included in the set of *if*-relevant worlds for a second strict conditional, then since the second quantifies over more possibilities it is a stricter strict conditional.

Fact 2. Suppose $(if_1\ p)(q)$ is a strict conditional wrt $c_1(w)$ and $(if_2\ p)(q)$ is a strict conditional wrt $c_2(w)$. If $c_1(w) \subseteq c_2(w)$ then $(if_2\ p)(q)$ implies $(if_1\ p)(q)$.

This way of thinking about conditionals treats them as restricted necessity operators, saying that their consequents are true throughout a given set of antecedent worlds. Since we can probe necessity operators by examining the properties of the functions which determine the sets of worlds they quantify over, the same is true of restricted necessity and so of strict conditionals. For instance: suppose that every world is relevant to an *if* at that world. That means that c is *reflexive*: for every w it is the case that $w \in c(w)$.

Fact 3. c is reflexive iff $(if\ p)(q)$ implies $p \supset q$.

Two comments. First: this amounts to saying that *if* is on the spectrum of logical strength, occupying a place *no weaker* than the material conditional. (Since $c(w)$ is always a set of worlds we have built-in that strict implication is at least as strong as *if*.) Since the material conditional together with its antecedent entails its consequent (on any sensible notion of "entails") it follows that being stricter than the material conditional means going in for some version of *modus ponens*. We will come back to this. Second: this follows straightaway from the fact that $(if\ p)(q)$ with respect to $c(w)$ is equivalent to $\Box_{c(w)}(p \supset q)$ and the fact that in modal logic reflexive accessibility relations (or functions or spheres or whatever) correspond to the validity of instances of the T axiom $\Box p \supset p$.

Another sort of property is the package of import/export equivalences.

Import/export $(if\ p \wedge q)(r) \dashv\models (if\ p)((if\ q)(r))$

Some potential import/export pairs for indicatives:

(9) a. If Carl is away, then if Lenny is away, then Sector 7G is empty.
b. If Carl is away and Lenny is away, then Sector 7G is empty.

And for counterfactuals:

(10) a. If Alex had come to the party, then if Billy had come to the party it would have been great fun.
b. If Alex had come to the party and Billy had come to the party, it would have been great fun.

Once we are thinking of conditionals as restricted necessity operators, import/export reads a lot like some sort of constraint on introspection. That's close to right.[10]

Fact 4. $(\mathit{if}\,\cdot)(\cdot)$ supports the right-to-left direction of import/export iff c is *shift reflexive*. That is: iff $v \in c(w)$ implies $v \in c(v)$. It supports the left-to-right direction iff c is *shift coreflexive*. That is: iff $v \in c(w)$ and $v \in c(u)$ implies $u = v$.[11]

Together (shift) reflexivity/coreflexivity – that is, both halves of import/export – impose a very strong requirement: that whenever a world is *if*-relevant at w that world is related to itself and to no other. (This property is what Kaufmann and Kaufmann call "shift identity.") That seems to be a weird requirement.

Matters get immediately worse. Combining reflexivity of the assignment of *if*-relevant possibilities with shift reflexivity/coreflexivity means that that assignment is an island function: every world is an *if*-relevant island to a conditional at that world (for every w: $c(w) = \{w\}$).

Fact 5. $(\mathit{if}\,\cdot)(\cdot)$ implies the corresponding material conditional and supports import/export iff for every w: $c(w) = \{w\}$.

As we saw: a strict conditional over such island sets of *if*-relevant possibilities is just the material conditional. So any conditional comparable to and no weaker than material implication that supports import/export must be the material conditional. Such "collapse" arguments serve as clear maps to the landscape of conditionals (especially indicatives). We will return to this theme.

There are other properties that strict conditionals (of whatever strictness) have, irrespective of the properties of the sets of *if*-relevant possibilities. I will mention three.

Antecedent strengthening $(\mathit{if}\,p)(q) \vDash (\mathit{if}\,p \wedge r)(q)$ for any r
Transitivity $(\mathit{if}\,p)(q), (\mathit{if}\,q)(r) \vDash (\mathit{if}\,p)(r)$
Contraposition $(\mathit{if}\,p)(q) \vDash (\mathit{if}\,\neg q)(\neg p)$

Fact 6. Any strict conditional supports antecedent strengthening, transitivity, and contraposition.

The reason for all three properties is simple: strict conditionals are universal quantifiers, saying all the *if*-relevant possibilities are of a certain sort. And the thing about *all*: all-claims are downward monotone, support transitive inferences, and contrapose.[12] Some quick Venn diagrams will convince the unmoved.

These properties push away from strict conditional analyses of (especially) counterfactuals, and (as we'll see) predicting that these patterns are patterns of non-entailment is a highlight of the classic *variably strict* theory developed initially by Stalnaker (1968; 1984) and Lewis (1973). Some concrete counter-examples:

(11) a. If Sophie had gone to the parade, she would have seen Pedro dance.
??So: If Sophie had gone to the parade and been stuck behind someone tall, she would have seen Pedro dance.
b. If Hoover had been a communist, he would have been a traitor.
If Hoover had been born a Russian, he would have been a communist.
??So: If Hoover had been born a Russian, he would have been a traitor.
c. If it had rained, it wouldn't have poured.
??So: If it had poured, it wouldn't have rained.

In fact the indicative counterparts here also make trouble for strict conditional accounts of indicatives. Set this aside for now.

4 Variably Strict Conditionals

We have come this far without saying whether the *if*s at stake are indicatives or counterfactuals. Let's change that by focusing on counterfactuals (though, not quite exclusively). The classic account of counterfactuals, and by far the account that remains dominant, treats them as *variably strict conditionals* (Stalnaker, 1968; Lewis, 1973).

Look again at (11a). This is problematic for strict conditionals since it seems eminently possible that (i) had Sophie gone she would have seen Pedro dance, and (translating to our formal language) so (ii) the conditional $(\mathit{if}\ p)(q)$ is true. Though, admittedly, (iii) not if she had been stuck behind someone tall. So, (iv) the counterfactual $(\mathit{if}\ p \wedge r)(q)$ is false and, it seems, (v) the contrary conditional $(\mathit{if}\ p \wedge r)(\neg q)$ is true. Strict conditionals don't seem to have the needed flexibility to allow both (ii) and (v). Put another way: sequences of counterfactuals like $(\mathit{if}\ p)(q)\,;(\mathit{if}\ p \wedge r)(\neg q)$ seem like they can be consistent – both conditionals can be non-vacuously true at the same time. Since that's not true of strict conditionals, Lewis (1973) argued on this basis that counterfactuals can't be any strict conditional no matter the level of strictness.

Some examples:

(12) a. If the USA threw its weapons into the sea tomorrow, there would be war;
b. But if the USA and the other nuclear powers threw all their weapons into the sea tomorrow, there would be peace.

(13) a. If you had been standing a foot to the left, you would have been killed;
b. But if you had (also) been wearing your hard hat, you would have been alright.

(14) a. If Sophie had gone to the parade, she would have seen Pedro dance;
b. But if Sophie had gone to the parade and been stuck behind someone tall, she would not have seen Pedro dance.

With a little ingenuity, it seems each sequence can be extended for as long as you like, with each successive conditional having an ever-stronger antecedent and the consequent flipping from negated to not. Such sequences are called *Sobel sequences*.[13] Analyzing any Sobel sequence as a sequence of strict conditionals, no matter the strictness, won't work and the reason is just that strict conditionals support antecedent strengthening.

Lewis's conclusion is that there is no level of strictness such that in a given situation counterfactuals are strict conditionals of that strictness. Instead, they are variably strict

conditionals: they are more or less strict depending on the strengths of their antecedents. Intuitively (with a not insubstantial additional assumption that we'll return to) a counterfactual like (14a) says that all of the possibilities most similar to ours but in which Sophie went to the parade are possibilities wherein she witnessed Pedro's dancing. The "thinned" (14b) on the other hand says something about all of the possibilities most similar to ours but in which Sophie went to the parade *and* was stuck behind someone tall (namely that in those worlds she missed out on the dancing). These are compatible so long as the (modally) nearest go-to-the-parade possibilities do not include the nearest go-to-the-parade-and-get-stuck-behind-someone-tall possibilities.

To make this less impressionistic: rather than simply associating with each world w a set $c(w)$ of *if*-relevant possibilities – possibilities relevant regardless of the *if* – we want to look at the nearest or most similar possibilities to w that make a particular antecedent true. So we need some (context-dependent) measure of relative similarity or nearness or closeness of worlds to w. We'll write it this way: $\leq_w$, with the idea that if $v \leq_w u$ then v is at least as close to w as u is.[14] Officially we are thinking that the context c determines such an ordering for each world, but we won't say how that happens and will generally suppress mention of c. Even before saying anything about this relation we know how the story will appeal to it.

Definition 3 (Variably strict conditionals). Conditionals are variably strict conditionals:

$$[\![(\mathit{if}\ p)(q)]\!]\,c,w = 1 \text{ iff } \text{if } v \text{ is a} \leq_w\text{-minimal } p\text{-world then } [\![q]\!]\,c,v = 1$$

where a world v is a $\leq_w$-minimal p-world iff there is no p-world u such that $u <_w v$.

Given this setup, there are some straightforward things to be said about the nearness ordering. For one thing, it has to actually *be* an ordering. For another thing, it should respect the fact that each world is an awful lot like itself and so pretty close to itself.

Definition 4 (Relative similarity). For any worlds w, v let $\leq_w$ be such that:

(i) (Ordering Assumption) $\leq_w$ is a connected and transitive relation over W.
(ii) (Centering Assumption) w is minimal in $\leq_w$: if $v \leq_w w$ then $w = v$.

Together Definition 3 and Definition 4 form the bare bones of the story.[15]

There are other notable assumptions we might add to it by imposing further constraints on the ordering (for any proposition X and world w):

(iii) (Limit Assumption) X has at least one $\leq_w$-minimal world.
(iv) (Uniqueness Assumption) X has no more than one $\leq_w$-minimal world.

Stalnaker's (1968) setup makes both of these additional assumptions, while Lewis's (1973) makes neither. Some of the properties are directly reflected in logical principles. For instance:

Conditional excluded middle $\models (\mathit{if}\ p)(q) \vee (\mathit{if}\ p)(\neg q)$

Fact 7. If $\leq_w$ satisfies both the Limit Assumption and the Uniqueness Assumption then $(\mathit{if}\ \cdot)(\cdot)$ supports conditional excluded middle.

The additional assumptions on the orderings are separable. I won't be assuming uniqueness (for the most part) but will make the limit assumption – indeed, above in Definition 3 I already made the Limit Assumption.[16]

It is easy to see why this approach is attractive. Take our Sobel sequences (12)–(14). If the conditionals are variably strict then no wonder they are consistent: in each case the first conditional takes us to the nearest possibilities in which a simple antecedent is true, but the second one takes us to a set of possibilities in which *in addition* some other thing is true. Since these need not be the same (indeed, aren't), the two conditionals end up talking about different possibilities.

The same goes for the problematic entailments that strict conditionals support.

Fact 8. Variably strict conditionals do not support antecedent strengthening, transitivity, or contraposition.

Variably strict conditionals don't validate any of these patterns and that is in their favor as a theory of counterfactuals in natural language.

Given our assumptions, we could easily retell the story in terms of sets of (antecedent specific) *if*-relevant worlds rather than the (family of) nearness or similarity orderings by, for a given world w and antecedent p, collecting up the set of worlds no further from w than the nearest p-world.

Definition 5 $c(w) = \lambda p\,.\{v$: if u is a minimal p-world in $\leq_w$ then $u \not<_w v\}$

One thing to notice is that centering (actually, weak centering) translates to the constraint that for any w and (consistent) p it is the case that $w \in c(w)(p)$. That means that counterfactuals would support *modus ponens*, and *that* seems strange since counterfactuals carry some sort of signal that their antecedents are false and those aren't the kinds of things that *modus ponens* comes up for.[17] Still, I think this is as it should be.

(15) a. Alex: If my keys had been in the drawer, I would have seen them.
b. Billy: No, look: they were in the drawer under the mail and you missed them!

Billy's denial here makes sense because the truth of the counter-example ($p \wedge \neg q$) at a world is always sufficient for the falsity of the counterfactual (*if* p)(q) at that world. And that is what (weak) centering imposes.

So we have reflexivity. Since variably strict conditionals are stronger than material conditionals (i.e., the sets of relevant *if*-worlds aren't always trivial islands) we know that variably strict conditionals can't validate import/export.

Fact 9. Variably strict conditionals do not support import/export.

Import/export would require that the closest q-worlds to the closest p-worlds are the same as the closest ($p \wedge q$)-worlds. Counter-examples (of the formal stripe) are easy to construct. For instance: suppose we have just the worlds w, x, y, z where p is true at x and y while q is true at y and z. Now, let $\leq_w$ be the ordering $w \leq_w x \leq_w y \leq_w z$. Thus the ($\leq_w$-)nearest ($p \wedge q$)-world to w is y. Finally, let $\leq_x$ be such that $z <_x y$. Thus the ($\leq_x$-)nearest q-world to the ($\leq_w$-)nearest p-world to w isn't y.

As we saw with conditional excluded middle (and the Limit Assumption) properties of the nearness relations (metaphor!) make for differences in the properties that an analysis of

conditionals based on them has. But disagreements about the properties of the nearness relation can seem to be bigger than they in fact are. Assume for simplicity that the space of worlds is finite. Then there are two natural decision points. First decision point: does the ordering permit ties? That is, is the case that two distinct worlds u and v can be tied in closeness or similarity to a world w? Adopting the Uniqueness Assumption prohibits ties. Second decision point: must all worlds always be comparable? That is, (for any w, u, v) is it the case that either $u \leq_w v$ or $v \leq_w u$? In principle these are separate questions, but in practice the dividing lines are whether ties and incomparabilities are both prohibited (Stalnaker), whether ties are permitted but incomparabiltities are not (Lewis), or whether both ties and incompatibilities are permitted (Pollock).

But, as Lewis (1981) showed, there is less disagreement here than appears. Suppose our ordering permits neither ties nor incomparabilities. That's true for any *fixed* and *determinate* ordering and, for all that we've said so far, it's possible that ordinary contexts don't always determine unique orderings. In such contexts there are, let's say, multiple admissible orderings. Then supervaluating over the admissible orderings gives determinate truth-conditions for simple conditionals just like we would get from a theory that permits ties but not incomparabilities.[18] And similarly for the second choice point. A theory that permits ties but not incomparabilities but allows that there may be a range of admissible orderings in any given context is, in this same sense, equivalent to a theory like Pollock's (1976) which permits both ties and incomparabilities.

There is one more set of equivalences between theories to round out this part of the discussion. One way to make sense out of the idea of conditional information is embodied by (some version of) the Ramsey test.

> **Ramsey test** (*if p*)(*q*) is true/accurate/acceptable in a situation iff *q* is true or accurate or acceptable in that situation-plus-the-information-that-*p*.

Depending on what we say about "true/accurate/acceptable," "situations," and "situation-plus-the-information-that-*p*" we get different theories.[19]

There are ways of filling in those details for counterfactuals. Most prominently among them are versions of *premise semantics*.[20] The idea is that (relative to a context, just as with the orderings) we associate with each world a set of propositions true at that world, a premise set P_w at w, and use that as the factual background to assessing a counterfactual's truth at w. Just like with similarity orderings, this assignment depends on context, though we won't say just how. A conditional (*if p*)(*q*) is true at a world iff every way of consistently adding the information that p to those premises gives us a derived or subordinate set of premises that entails q.

Let's say things a little more precisely (still sticking to the assumption that W is finite) so we can say how this setup relates to the variably strict picture.

> **Definition 6** (Premise sets). For every world w there is a set P_w of propositions such that:
>
> (i) (Exhaustive Assumption) Every world belongs to some proposition in P_w ($\cup P_w = W$).
> (ii) (Centering Assumption) Every member of P_w is true at w and w only ($\cap P_w = \{w\}$).
>
> For any proposition X let $\mathbf{P}_w^X$ be the set of maximal X-consistent subsets of P_w.[21]

The first assumption plays the role of the Ordering Assumption for variably strict conditionals (our orderings left out no worlds) and the second assumption plays the role of centering (naturally enough).

Counterfactuals ask us what follows from the minimal ways of making room for the antecedent. So we look to the maximal p-consistent subsets of our premise set and see what follows from them.

Definition 7 (Conditionals and premise sets). Conditionals are minimally revised premise set entailments:

$$[\![(\mathit{if}\ p)(q)]\!]\ c,w = 1 \text{ iff if } P^{\star}_{w} \in \mathbf{P}\ w\ [\![p]\!] \text{ then } P^{\star}_{w} \text{ entails } [\![q]\!].$$

Lewis (1981) showed that such a theory is equivalent to a theory based on orderings that permits ties and incomparabilities between worlds. There are ways of turning premise sets into an ordering and the result of doing that gives us an ordering that says a counterfactual is true iff our original premise set did. (Going the other way, every ordering can be derived in this way from some premise set, with the same result.) It is the deriving of orderings from premise sets that is key:

Fact 10. A premise set P_w induces an ordering $\leq^{P}_{w}$ where $u \leq^{P}_{w} v$ iff every proposition in P_w true at v is true at u (that is: iff $\{X \in P\ w\colon u \in X\} \subseteq \{X \in P\ w\colon v \in X\}$). A conditional $(\mathit{if}\ p)(q)$ is true with resect to P_w iff it is true with respect to $\leq^{P}_{w}$.

So premise semantics and ordering semantics can both be sensibly seen as different but broadly equivalent implementations of the variably strict theory.[22]

5 Counterfactual Dynamics

Taking counterfactuals to be variably strict conditionals is the industry standard. But it is open to challenge.[23] A lot of weight has been put on the basic logic that variably strict conditionals deliver. But things are more subtle, and way more interesting, than they at first appear.

Look again at our examples of antecedent strengthening gone wrong (12)–(14). These bear important weight in the argument against taking counterfactuals to be any strict conditional. If they were any strict conditional, each pair would be incompatible, but they are as normal as counterfactual discourse ever gets. But as normal as they are, they are dramatically not that – indeed they seem contradictory – when issued in reverse order as *reverse Sobel sequences*.[24] Look at the difference with Lewis's example. Here is the (a)→(b) direction we saw before:

(12) a. If the USA threw its weapons into the sea tomorrow, there would be war;
b. But if the USA and the other nuclear powers threw all their weapons into the sea tomorrow, there would be peace.

And the reversed (b)→(a) direction:

(16) ??If the USA and the other nuclear powers threw all their weapons into the sea tomorrow, there would be peace; but if the USA threw its weapons into the sea tomorrow, there would be war.

Another of our (a)→(b) examples and its reversed (b)→(a) counterpart:

(14) a. If Sophie had gone to the parade, she would have seen Pedro dance;
b. But if Sophie had gone to the parade and been stuck behind someone tall, she would not have seen Pedro dance.

(17) ??If Sophie had gone to the parade and been stuck behind someone tall, she would not have seen Pedro dance; but if Sophie had gone to the parade, she would have seen Pedro dance.

There's no doubting the asymmetry here: unfolding a Sobel sequence (and so a counter-example to antecedent strengthening) from (a)→(b) is one thing, reversing the order from (b)→(a) is another thing entirely. But, from the variably strict point of view, once a counter-example to antecedent strengthening always a counter-example. Fiddling with the order in which we find the nearest worlds in which the USA throws its weapons into the sea tomorrow (maybe not so close) versus finding the nearest worlds in which the USA *and* all the other nuclear powers throw their weapons into the sea tomorrow (even further away) shouldn't change the fact that the sets we get are different in those different cases. This is puzzling.

The argument against treating counterfactuals as strict conditionals that is based on Sobel sequences isn't airtight. Sobel sequences show that counterfactuals aren't strict conditionals so long as the level of strictness never changes as counterfactual discourse unfolds. So there's an unargued-for assumption. Reverse Sobel sequences give us a reason to explore life without it.[25]

I will sketch a version of the strict conditional theory initially developed by von Fintel (2001) and then (not quite conservatively) extended in Gillies 2007. There are three ingredients to the story.[26]

Context keeps track of what worlds are counterfactually relevant.[27] Begin with a system of spheres around a world w: a nested set of sets of worlds $c(w)$ such that $\{w\} \in c(w)$ and $\cup c(w) = W$. Assume that context keeps track of such a set and that it determines the counterfactually relevant worlds.

Definition 8 The default *hyperdomain* at w in c is $\pi_c^0 = c(w)$. Given a hyperdomain π_c the *domain* of counterfactually relevant worlds (a.k.a. the *modal horizon*) s_{π_c} is the $\subseteq$-minimal domain in π_c.

So the default modal horizon at w is $s_{\pi^0} = \{w\}$. (When the context is clear (or not relevant since the counterfactual domains are the only things we are keeping track of here) we will omit reference to c.)

Conditionals presuppose that their antecedents are compatible with the relevant domain that the conditionals talk about. So counterfactuals presuppose that their antecedents are compatible with the counterfactual domain.

Entertainability presupposition A counterfactual (*if p*)(*q*) in context *c* presupposes that s_{π_c} contains some *p*-worlds.

Sometimes an assertion can be successful even if it has unmet presuppositions. That is because sometimes (*ceteris paribus* and within certain limits) we accommodate the missing presupposition and evaluate the assertion not with respect to the context as it was when the utterance was made but in the context changed to accommodate the missing presupposition.[28] And so it is with counterfactuals and their entertainability presuppositions. Asserting a counterfactual may change the conversational score when the presupposition is accommodated.

Definition 9 (Context change via accommodation). Let *c* be any context and *p* any counterfactual antecedent. Then $c|p|$ is the posterior context that results from accommodating the entertainability of *p* into *c* where

$$\pi_{c|p|} = \{s \in \pi\, c\colon\ s \cap [\![p]\!] \neq \varnothing\}$$

Notice that if s_{π_c} – the $\subseteq$-minimal domain in π_c – is compatible with *p* then $\pi_{c|p|} = \pi$. Otherwise $\pi_{c|p|}$ is the result of eliminating inner sets of worlds from π_c until we get one that has some *p*-worlds in it.

Putting the pieces together:

Definition 10 (Dynamic strict counterfactuals v.1.0). Counterfactuals are dynamic strict conditionals that carry entertainability presuppositions:

$$[\![(\mathit{if}\, p)\,(q)]\!]\ c,w{=}1 \text{ iff } (s_{\pi_{c|p|}} \cap [\![p]\!]) \subseteq [\![q]\!]$$

This is equivalent to saying that the counterfactual is true iff the corresponding material conditional is $\Box s_{\pi_{c|p|}}$-necessary.[29] So a counterfactual (*if p*)(*q*) in a context *c* presupposes that *p* might have been the case and then asserts the strict conditional $\Box(p \supset q)$ with respect to the post-accommodation domain provided by *c*-changed-just-a-bit.

Accommodation works by admitting as relevant the worlds as close as the nearest antecedent world.[30] Since we begin by default with the counterfactual domain containing just the world of evaluation, this means that the dynamic theory captures the variably strict theory as a special case when counterfactual discourse stretches only one conditional long.

Fact 11. Suppose context *c* delivers a system of spheres S_w. Then a counterfactual (*if p*)(*q*) is true at *w* in *c* according to the variably strict semantics iff it is true at *w* in *c* according to the dynamic strict conditional theory.

Things are different for sequences of counterfactuals. The dynamic theory treats counterfactuals as context dependent and context affecting. Context dependent because the modal horizon is a function of context. Context affecting because what worlds are counterfactually relevant can be changed by a counterfactual's antecedent. It is this interplay that explains the asymmetry between (a)→(b) Sobel sequences like (12) and (14) and their (b)→(a) reverse Sobel sequences like (16) and (17).

Here's how. Suppose *p* is false at *w* but that the nearest *p*-worlds to *w* are *q*-worlds. For instance: suppose that Sophie did not go to the parade and Pedro was conspicuous and

reliably a dancer at the parade. The default domain $\{w\}$ doesn't satisfy the counterfactual's presupposition. So we accommodate. It's possible for all the p-worlds in $s_{c|p|}$ to be q-worlds and so for $(if\ p)(q)$ to be true.

Now we come to the second counterfactual in an (a)→(b) Sobel sequence. But the context is not the default initial context. It is $c|p|$. Still, it is possible that there are no r-worlds in $s_{\pi_{c|p|}}$. (Sophie is not overly tall and doesn't generally travel with stilts.) The presupposition of $(if\ p \wedge r)(\neg q)$ isn't met so we accommodate. It's possible for all the $(p \wedge r)$-worlds in $s_{\pi_{c|p\wedge r|}}$ to be $\neg q$-worlds: the nearest worlds where Sophie gets stuck behind someone tall can all be worlds where she doesn't see Pedro dance.[31] So the counterfactual $(if\ p \wedge r)(\neg q)$ can be true, too.

The (b)→(a) direction is different. If we *first* accommodate the antecedent of the (b) counterfactual $(if\ p \wedge r)(\neg q)$ we go straightaway to context $c|p \wedge r|$. Assume that indeed all the $(p \wedge r)$-worlds in $s_{\pi_{c|p\wedge r|}}$ are $\neg q$-worlds so that $(if\ p \wedge r)(\neg q)$ is true. There is now no room for the simple (a) conditional to be true in the context $c|p \wedge r|$. That is because its presupposition – that p is possible relative to $c|(p \wedge r)|$ – is satisfied. Hence: no accommodation. But we just said that all the $(p \wedge r)$-worlds in $s_{\pi_{c|(p\wedge r)|}}$ are $\neg q$-worlds. And so it's false that all the p-worlds in $s_{\pi_{c|(p\wedge r)|}}$ are q-worlds. So the simple (a) counterfactual can't be true.

Members of Sobel sequences end up quantifying over different domains; members of reverse Sobel sequences end up quantifying over the same domain. No wonder there is an asymmetry. Figure 17.2 shows how this works graphically. For those who want to see this in slightly more formal terms, we need one more definition.

Definition 11 Let $C_0; \ldots; C_n$ be a sequence of counterfactuals and a_i be the antecedent of the ith counterfactual. Such a sequence is *satisfiable* iff there is a world w and a system of spheres $c(w)$ such that: (i) $[\![C\,0]\!]\ c\,0,w = \ldots = [\![C\,n]\!]\ c\,n,w = 1$, where (ii) $\pi^0_{c_0} = c(w)$ and (iii) $c_{i+1} = c_i|a_i|$ (for each $i > 0$).

This just captures what we have been assuming in working through the Sobel sequences: that interpreting counterfactuals changes the context and those changes can matter when it comes to seeing when a sequence is consistent or not.

Fact 12. Sobel sequences $(if\ p)(q)$; $(if\ p \wedge r)(\neg q)$ are satisfiable according to the dynamic strict conditional theory. Reverse Sobel sequences $(if\ p \wedge r)(\neg q)$; $(if\ p)(q)$ are not satisfiable.

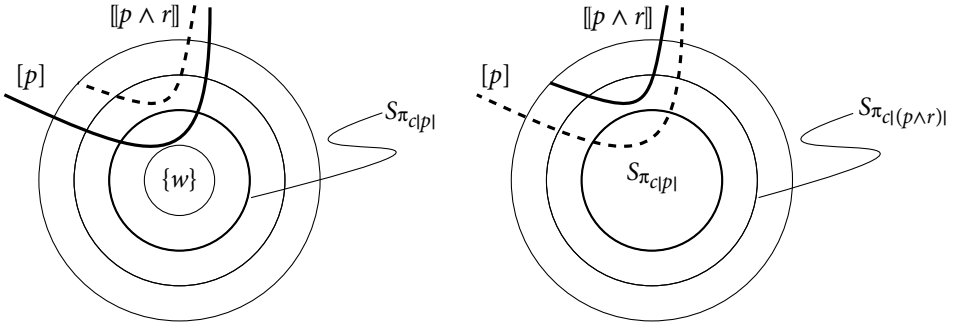

Figure 17.2 Accommodating p as a possibility (left) and $(p \wedge r)$ as a possibility (right).

The last word here has yet to be had. Counterfactual domains seem to get ever-larger. So one question: How do counterfactual domains get *reset*? Indeed there are examples (discussed in von Fintel, 2001, §8, and Gillies, 2007, §9) in which somehow or other the accommodation that a counterfactual's antecedent seems to trigger is promptly undone.

(18) If Sophie had gone to the parade and been stuck behind someone tall, she wouldn't have seen Pedro dance. Still, if Sophie had gone to the parade, she wouldn't have been stuck behind someone tall.

Some (for instance Moss, 2012) think the phenomenon tells decisively against the dynamic strict conditional theory. But there is room to move and the sort of thing that needs saying is clear: resetting happens, but it is not as smooth as expanding the counterfactual domain. There is evidence in favor of this, though the mechanism is poorly (i.e., not at all) understood. Some evidence that von Fintel discusses: modal and (certain) factual information makes the resetting smoother:

(19) If the USA threw its weapons into the sea tomorrow, there would be war. Well, if all the nuclear powers threw their weapons into the sea tomorrow, there would be peace. *But of course, that would never happen*. So, as things stand, if the USA threw its weapons into the sea tomorrow, there would be war.

(20) A: If John had been at the party, it would have been much more fun.
B: Well, if John had been at the party and had gotten into a fight with Perry, that wouldn't have been any fun at all.
A: *Yes, but Perry wasn't there*. So, if John had been at the party, he wouldn't have gotten into a fight with Perry.

Part of what makes this situation puzzling is that retreating to the variably strict theory does not seem like the right path. The reason has to do with *negative polarity items* (NPIs) like *any* and *ever* and when they are licensed. Some examples:

(21) a. Every diner who has *ever* eaten there has liked it.
b. Every diner who ordered *any* dessert loved it.
c. *Some diner who has *ever* eaten there has liked it.
d. *Some diner who ate there has *any* reason to go back.

Quantificational claims like these combine a quantificational determiner $\mathcal{Q}$ with a *restrictor* A and a *nuclear scope* B, saying that $\mathcal{Q}$-many of the As are B's. Some determiners (universal ones like *every*) are *downward entailing* in their first argument: *every* $(A)(B) \vDash$ *every* $(A')(B)$ if $A' \subseteq A$. And some (like *some*) are not: *some* $(A)(B) \nvDash$ *some* $(A')(B)$ for *some* $A' \subseteq A$. (In fact *some* isn't downward entailing in either argument.) Instead *some* is upward entailing in its first argument. Ladusaw (1980) was the first to argue that NPIs are licensed only when they are in a downward entailing environment. That elegantly predicts the distribution in (21). It is in fact a very robust generalization.

Counterfactual antecedents can also contain NPIs. This (as argued in von Fintel, 2001, and in von Fintel and Gillies, 2015) is trouble-making for any retreat to a variably strict theory.

(22) a. If you had eaten *any* fruit, you would have had an apple.
b. If you had *ever* been to Idaho, you would have liked it.

The trouble is that the antecedent of a variably strict conditional is not a downward monotone environment. Given our setup we can say something very stark.

Fact 13. A conditional $(\mathit{if}\ \cdot)(\cdot)$ is downward entailing in its antecedent iff it supports antecedent strengthening.

Antecedent strengthening is of course just what the variably strict conditional is designed to do without. Whence it leaves unexplained why counterfactual antecedents license NPIs. The variably strict conditional theory gets this wrong for exactly the reason the strict conditional theory gets it right.

6 Indicative Conditionals and Collapse

We know that logical space is limited for a conditional that is bounded by strict implication (from Fact 5) and material implication (from below) and supports import/export. Material conditionals seem to be the only option. So if you are not satisfied with the horseshoe as a theory of ordinary indicative conditionals, you have choices to make. They are not easy choices.[32]

Another collapse argument:

(23) Either the butler did it or the gardener did.
So: if it wasn't the butler, it was the gardener.

Patterns like this – the *direct argument* or more descriptively *or*-to-*if* – seem like entailments. But that makes for immediate trouble.

Fact 14. If $p \vee q \vDash (\mathit{if}\ \neg p)(q)$ then $p \supset q \vDash (\mathit{if}\ p)(q)$.

The proof is simple: suppose $p \supset q$ is true (at w in c). Then so is $\neg p \vee q$ and hence by *or*-to-*if* so is the indicative $(\mathit{if}\ p)(q)$. If indicatives are bound from below by material conditionals, then we have the stronger collapse conclusion: $(\mathit{if}\ p)(q) \dashv\vDash p \supset q$.

These seem like puzzles. Perhaps even puzzles-in-the-pejorative-sense (whatever that is). But the issue collapse arguments like these bring out is bigger than that. Indicative conditionals seem to be stronger than their corresponding material conditionals. They seem to express something more. But what this more is and how it gets expressed is not obvious. Collapse arguments like these are good ways of mapping logical space for how to think about this problem. But they also reveal that the going won't be easy (the assumptions they require are modest and super plausible).

So, one option is to deny the lower bound. If that is right then the truth of a counterexample $(p \wedge \neg q)$ isn't always sufficient for the falsity of the indicative $(\mathit{if}\ p)(q)$. And so, if indicatives do not entail their corresponding material conditionals, it is possible for $(\mathit{if}\ p)(q)$ and p to both be true, but for q to be false. It's not enough to just deny an assumption: what we need is a reason for thinking we should drop it. So we need reasons to think $(p \wedge \neg q)$ isn't always sufficient for the falsity of the indicative $(\mathit{if}\ p)(q)$. And there are (some say) concrete examples to be found. McGee's (1985) example:

(24) If a Republican won, then if Reagan didn't win Anderson did.

It seems possible to be in favor of a right-nested indicative like (24), and to be in favor of its antecedent, without being particularly attracted to the embedded conditional considered on its own. That doesn't yet fit the bill for what needs doing, but it is a start.[33] It is safe to say that this has not turned out to be the favored route.

Another option: perhaps indicative conditionals do not support import/export. As we have already seen, variably strict conditionals do not. So if indicatives are variably strict, then they won't. Stalnaker (1975) – rightly, I think – takes counterfactuals and indicatives to share the same core semantics. Since there are good reasons for the variably strict picture of counterfactuals, there are good reasons for that picture here, too. The reasons (as we'll see) have little to do with import/export.

Indicatives and counterfactuals are different: witness Adams pairs like (3a) and (3b). The idea is that they nevertheless share the common semantic core of variably strictness. What sets indicatives apart is a pragmatic constraint on their proper use: indicative conditionals say something about the not-yet-ruled-out worlds in a context.

Pragmatic constraint If p is compatible with the context c, then the $\leq_w$-minimal p-world(s) are compatible with c.

The constraint can be suspended – that, arguably, is what the distinctive tense/aspect marking of "subjunctive" conditionals does.

Strict conditionals are stronger than material conditionals, so we know that (under plausible assumptions about entailment) *or*-to-*if* inferences like (23) can't be entailments.[34]

Fact 15. If $(\mathit{if}\,\cdot)(\cdot)$ is a variably strict conditional then $p \vee q \not\models (\mathit{if}\,\neg p)(q)$.

Why then do instances of this pattern like (25) seem like entailments?

(25) Either the butler did it or the gardener did it.
So: if the butler didn't do it, then the gardener did it.

Stalnaker's answer: because there is a nearby pragmatic property – *reasonable inference* – that they do have.

Definition 12 (Reasonable inference). Suppose p is successfully asserted (at w in c) and c' is the resulting posterior context. $p, so: q$ is a *reasonable inference* iff q is accepted in c'.

Suppose that in order for a disjunction $p \vee q$ to be appropriately asserted in a context c that c has to have some $(p \wedge \neg q)$-worlds compatible with it and also some $(\neg p \wedge q)$-worlds compatible with it.[35] To be accepted in a context a sentence must be true at every world compatible with it. So if a disjunction is successfully asserted in c then $\neg(p \wedge q)$ is accepted in c'. Then anytime $p \vee q$ is appropriately asserted we will end up in a context in which the indicative $(\mathit{if}\,\neg p)(q)$ is accepted.[36]

Fact 16. If $(\mathit{if}\,\cdot)(\cdot)$ is variably strict and obeys the pragmatic constraint on indicatives then *or*-to-*if* is a reasonable inference.

This is an elegant solution. A crucial part of it is how it uses an independent and plausible pragmatic fact about disjunctions – that they are felicitous only when either conjunct might be true without the other – to get where we need to go. Therein lies the elegance. But there is no similar thing to be said about either right-nested conditionals like $(\textit{if}\ p)((\textit{if}\ q)(r))$ or their exported counterparts like $(\textit{if}\ p \wedge q)(r)$. So the strategy here leaves unexplained why import/export seems valid.

Collapse arguments rely (sometimes tacitly, sometimes not) on the assumption that indicative conditionals fit in with the rest of our linguistic tools in being vehicles that can be either true or false and have the same sort of semantic values that non-conditional language has. For that reason collapse arguments can be taken to be arguments for the thesis that indicative conditionals do not, after all, have truth-values or express normal semantic values. This is sometimes called the *no-truth-value* (NTV) theory.[37] The idea is that indicatives do not represent or report conditional information at all. Instead they are vehicles for expressing states of mind, in particular that the speaker has sufficiently high credence in the consequent given the antecedent. That is: they aren't things we assert, but things we use to make *conditional* assertions.[38]

There is a lot to be said for tying the appropriate use of conditionals to conditional assertion.[39] But NTV views are also hard to reconcile with a uniform picture of semantics. And, indeed, they are hard to square with why it is that conditionals mix with other, non-conditional, bits of language: they can be negated, they embed modal vocabulary, and they go in for quite a bit of nesting. Take the modals.

(26) a. If Red isn't in the box, Blue must be.
b. If Red isn't in the box, Blue might be.

Hypothesis: epistemic modality and indicative conditionals are tightly linked. Whatever kind of semantic-plus-pragmatic bundle we opt for in one case we should opt for the same sort of bundle in the other case. The dilemma in the offing here is that NTV either extends the thesis to the modals or not. If so, then since *must* and *might* aren't for asserting on their own, embedding them can't be something we do to conditionally assert them. So (26) are *prima facie* out. If not, then the attractive hypothesis linking modals and conditionals has to go.[40]

Even so, we may be driven in the NTV direction all the same. One reason (we won't really be able to do justice to it here): Lewis (1976) showed that (on pain of triviality) there is no two-place propositional operator such that the probability of the resulting proposition being true when given arguments p and q always equals $\Pr(q|p)$. Hence:

Fact 17. If $(\textit{if}\ p)(q)$ expresses a semantic value that determines a truth-value then it is not in general true that $\Pr((\textit{if}\ p)(q)) = \Pr(q|p)$.

In so far as we want our attitudes toward indicatives – the degree to which we believe them or want to assert them or bet on them or whatever – to track the corresponding conditional probabilities (and we do), that is an argument against assigning them truth-values.[41] But the argument can be resisted. As we will see, some theories (notably the "restrictor" theory developed by Kratzer, but also some others) seem to take triviality in stride.[42]

Another reason, due to Edgington (2008, §2; 2014): if indicatives have truth-conditions then those truth-conditions are either truth-functional or non-truth-functional. Neither seems right for indicatives. Consider non-truth-functional truth-conditions. (Truth-functional truth-conditions are a dead end because the horseshoe is the only

option.) Lack of truth-functonality requires *variability*. That is: the truth-values of p and q at w (in c) don't fix the truth-value of $(if\ p)(q)$ at w (in c). So if p is false at w and q is true at w then sometimes $(if\ p)(q)$ is true at w and sometimes it isn't. But indicatives seem to validate *or*-to-*if* and this requires *uniformity*. That is: if all the information you have is that $\neg p \vee q$ then that is always sufficient for $(if\ p)(q)$. Edgington says variability and uniformity are at odds and so no non-truth-functional theory can get this right. Conclusion: no way of assigning truth-conditions to indicatives can be right.

This is a compelling argument but it isn't airtight since there is room for a non-truth-functional theory to embrace both variability and uniformity. It is possible that the variability required by non-truth-functionality be variability in truth-value at a given world between contexts. And it is possible that the uniformity required by *or*-to-*if* be uniformity across worlds compatible with a given context. The master argument overlooks the possibility of such theories of indicatives.[43]

7 Antecedents as Restrictors

So far we have only been worrying about what various sorts of conditionals mean. There is an orthogonal issue: how are those meanings achieved by the *if*-of-English? We have assumed a straightforward answer: that the *if*-of-English is adequately represented in our regimented language by a binary connective $(if\ \cdot)(\cdot)$ and that this is assigned a uniform semantic value. But this is an assumption and can be challenged. In philosophy *can be challenged* often enough implies *has been challenged*. This is such a case.

Lewis (1975) argued that *if*s – apparently conditional expressions – in certain quantificational environments do not express any conditional thing. Example:

(27) $\left\{\begin{array}{c}\text{Always}\\ \text{Sometimes}\\ \text{Seldom}\end{array}\right\}$ if a farmer owns a donkey, he beats it.

What single thing could *if* mean in each of these and could that single thing be a conditional operator rightly so-called? The *if* might plausibly contribute some iffy meaning – for instance a strict conditional of some sort– when the quantifier is a universal like *always*. But conjunction is a better candidate if it's an existential like *sometimes*. Neither looks good for *seldom*.

In asking the question we assumed that we have two operators, a quantifier $@$ and a conditional $(if\ \cdot)(\cdot)$ and that the relevant structure of (27) sorts the scopes out this way:

(28) $@(if\ p)(q)$

That gets us into trouble so Lewis's (1975) conclusion is that sentences like those in (27) are not instances of a conditional operator plus an adverb of quantification.[44] We don't, appearances aside, have the two operators $@$ and $(if\ \cdot)(\cdot)$. Instead, he said, the *if*s in environments like these are a *non-connective* whose only job is to mark an argument slot for the adverb of quantification.[45]

The trouble-making feature is that *if*s under adverbs of quantification express restricted quantificational claims. In (27) those are claims about donkey-owning-farmer situations: that they are always/sometimes/seldom farmer-beating-donkey situations. There seems to be no way for the *if*s to both contribute a uniform conditional meaning and do this restricting. Since these *if*s restrict, they aren't iffy.

Kratzer's idea is that this holds not just for *if*s under adverbs of quantification but for all *if*s.[46] The picture is that *if* doesn't contribute a meaning, much less a conditional meaning, to the sentences in which it occurs:

> The history of the conditional is the history of a syntactic mistake. There is no two-place "if … then" connective in the logical forms for natural languages. "If"-clauses are devices for restricting the domains of various operators. (Kratzer, 1986, p. 11)

The thing all *if*s do is restrict operators (quantifiers, modals). So they aren't iffy. (What about bare conditionals, conditionals which appear not to have a nearby operator? Since the hypothesis is that *if*s are devices for restricting operators, there must be one. So we posit a covert, universal operator.)

Definition 13 (Restrictor analysis). Conditionals are restricted operators with logical forms like this:

$$\text{Quantifier/operator + if-clause + consequent clause} \quad \textsc{operator}_{(p)(q)}$$

Two things to notice. First: the binary connective $(\textit{if}\ \cdot)(\cdot)$ makes no appearance. The action is all about the operator. Second: for just that reason we won't have a story about "indicative conditionals" or "counterfactual conditionals." Instead, as we'll see, we get a story by saying something about the operators that the relevant *if*-clauses restrict. That's why this is less an issue about *what* various conditionals mean and more an issue about *how* natural language sentences manage to carry those meanings.

Figure 17.3 sketches the differences in structure. The left and center trees illustrate the structure where an operator and a conditional connective mix: the left is the case where the operator outscopes the conditional with antecedent p and consequent q and the center is the case of a conditional with antecedent p and complex consequent OPERATOR q. The rightmost tree shows the structure for the restrictor analysis. Here the "antecedent" is the restrictor for OPERATOR and the "consequent" q is the nuclear scope. (We'll now focus on the case where the operators involved are modals (as opposed to quantifiers).)

Take an ordinary counterfactual like (29):

(29) If Alex had been there, she would have had fun.

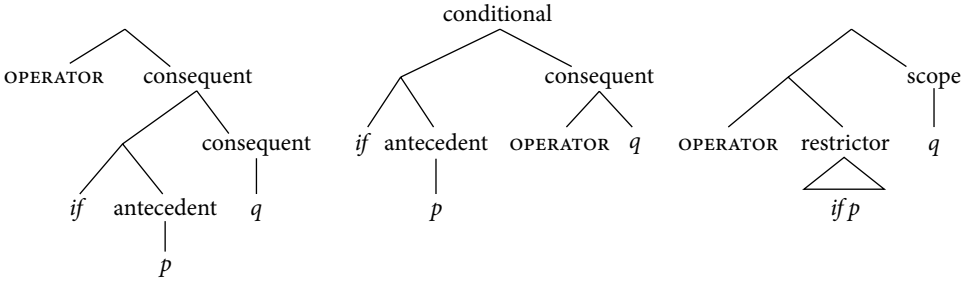

Figure 17.3 Operators + *if*: conditional versus restrictor.

So far, treating the (counterfactual) *if*-clause as a restrictor doesn't do much because we haven't yet said what the modal *would have* means.

In principle we could adapt just about any theory about what such conditionals mean to what such modals mean. Here we will (with some simplifications) follow Kratzer and give an analysis that makes the same predictions as the variably strict story. Here is the idea: modals quantify over a domain, saying that all or some of the best worlds in it (and in which some additional thing (provided by a restricting *if*-clause if there is one) is true) satisfy the prejacent (the scope). Context supplies the domain (the *modal base* at a world) and the notion of bestness (induced by the *ordering source* at a world).

Definition 14 (Modal base, ordering source). A *conversational background* is a function from worlds to sets of propositions. A *modal base B* is a conversational background. Similarly, an *ordering source O* is a conversational background. The *ideal worlds* at w relative to B and O is the set of worlds that are $\leq^{O}_{w}$-minimal in $\cap B(w)$ (where $\leq^{O}_{w}$ is the ordering induced by the set of propositions $O(w)$ used in Fact 10).

Contexts determine both a modal base and an ordering source. These are the same type of object, but they play different roles. Modal bases simply form domains. We aren't making use of their additional structure here, so we just take the image of a base B_w to get the worlds compatible with all the propositions in it. The extra structure in ordering sources – the extra structure over and above a set of worlds – is used. We use it to induce an ordering. The two pieces together get us the ideals.[47]

Context has the job of selecting values for the modal base and ordering source.[48] Once it does, the modal simply contributes (restricted) quantificational oomph.

Definition 15 (Modals). Suppose B is the modal base and O the ordering source determined by context c. Then:

(i) $[\![\textit{must/would}(p)(q)]\!]\, c,w = 1$ iff for every ideal v at w wrt $B \cup \{[\![p]\!]\}$ and O: $[\![q]\!]\ c,v = 1$.

(ii) $[\![\textit{might/might have}\ (p)(q)]\!]\, c,w = 1$ iff for some ideal v at w wrt $B \cup \{[\![p]\!]\}$ and O: $[\![q]\!]\ c,v = 1$.

The restrictor p simply augments the modal base. And so, together with Definition 13, that's all that *if*-clauses do.[49]

We have barely constrained what sorts of functions the backgrounds can be. Adding constraints gets us different possibilities for the flavor of the modal involved and the sort (and strength) of conditional. Some possibilities for a conversational background f:

- f is *realistic* iff for every w: $w \in \cap f(w)$.
- f is *totally realistic* iff for every w: $\cap f(w) = \{w\}$.

Backgrounds, like accessibility relations and accessibility functions, can also characterize sorts of contextually relevant information:

- f is an *epistemic* background iff (for every w) $f(w)$ is the set of propositions known to the c-relevant agents at w.

- *f* is a *stereotypical* background iff (for every *w*) *f*(*w*) is the set of propositions which normally hold at *w*.

And so on.

This predicts for a wide range of possible contextual resolutions for conditionals.

Fact 18. Material conditionals correspond to the special case where *B* is totally realistic and *O* is empty. Strict implication corresponds to the special case where both *B* is empty and *O* is empty.

To get a feel for this, let's walk through the material conditional case. Let *B* be a totally realistic background and *O* be empty. Then a conditional *if p*, (*must*) *q* – that is, *must* (*p*) (*q*) – at *w* says that the best worlds in $\cap B(w)$ that are *p*-worlds are all *q*-worlds. But $\cap B(w) = \{w\}$ and the induced ordering treats all worlds alike. So whether the conditional is true is down to *w* alone. Suppose *p* is true at *w*. Then the conditional is true iff *w* is a *q*-world. Suppose *p* is false at *w*. Then the conditional is vacuously true at *w* since there are no *p*-worlds in $\cap B(w)$. These are just the truth-conditions of the material conditional.

The empirical hypothesis is that counterfactuals are conditionals (which is to say "conditionals") interpreted against an empty modal base and a totally realistic ordering source. This is backed up by the following:

Fact 19. Let *B* be the empty modal base and *O* be the *c*-relevant totally realistic ordering source. Now take the premise set *P* to be such that for every *w*: $P_w = O(w)$. Then: $[\![\text{would}(p)(q)]\!]\ c,w = 1$ according to the restrictor analysis (Definition 15) iff $[\![(\textit{if}\ p)\ (q)]\!]\ c,w = 1$ according to the premise set analysis (Definition 7).

So premise sets correspond to special ordering sources and the analyses use them in the same way. Hence the (promised, and now delivered) equivalence.

All of this carries over to the case of indicatives. There the relevant modals are epistemic, taking an epistemic modal base and an empty ordering source. Doing things that way, as Kratzer (1986) argues, relieves some of the pressure in the collapse arguments we saw in §3 and §6. I want to mention just two examples for now.

The first: import/export. The trouble was that we couldn't, without collapse to the material conditional, both satisfy this and have the truth of a counter-example ($p \wedge \neg q$) always suffice for the falsity of the corresponding indicative (*if p*)(*q*). (Or, in this case, the corresponding modal *must*(*p*)(*q*).) Epistemic modal bases are realistic (since you can't know false things), so it would seem that we can't have import/export. But there is room for maneuvering for the restrictor view.

Fact 20. *must* (*p*) (*must* (*q*) (*r*)) $\dashv\models$ *must* (*p*$\wedge$*q*) (*r*)

How is this possible? Kratzer says that Gibbard's proof "does not threaten" this analysis, but doesn't really say more than that. The answer lies in the fact that conditionals ("conditionals") express different things when they occur on their own compared to when they occur embedded.[50]

The second: it is hard to see how the restricting behavior gets done if *if* expresses a *bona fide* conditional. This is part of what is going on in Lewis-style-triviality arguments. But there is an easy way out.

(30) a. If the bet is on odd, it's probably a loser.
probably $(p)(q)$
b. If the coin is fair, then the probability of heads is $\frac{1}{2}$.
$\frac{1}{2}$-*probable* $(p)(q)$

Filling in very off-the-shelf semantics for the probability modals here immediately predicts that (30a) is true iff the corresponding (c-relevant) conditional probability is high enough and that (30b)is true iff the relevant (c-relevant) conditional probability is 0.5. Triviality doesn't threaten because there is no separate conditional proposition that the probability modal takes scope over.[51]

Again, in principle the *if*s-as-restrictors picture is compatible with just about any story of the relevant modals and so can be made to come out equivalent to just about any story of conditionals. To reiterate: that fact goes in the pro column since one of the achievements here is to separate out questions about how conditional meanings get expressed from questions about what those conditional meanings are.

8 Dynamics and Indicative Conditionals

The dynamics of counterfactual domains highlights ways in which conditionals can be seen as *externally* dynamic: interpreting one sentence changes an essential component of conversational score that is relevant for the interpretation of a later sentence. Conditionals can also be thought of as *internally* dynamic: interpretation of one part of a sentence changes an essential component of conversational score that is relevant for the interpretation of a later bit of that same sentence.[52]

Let's explore that by sketching a dynamic semantics of indicative conditionals that is inspired by the Ramsey test. In fact, we will see two implementations of that theory: one implementation in a dynamic framework and one using the (seemingly) more familiar context-plus-index-delivers-truth-values setup we've mostly been assuming throughout. The first implementation is in Gillies (2004) and the second in Gillies (2009; 2010).[53] Taking indicatives to be dynamic (strict) conditionals offers a new perspective on the various collapse arguments, Edgington's "master argument" against truth-conditions, and a modal parallel to Lewis's argument about *if*s under adverbs of quantification.[54]

We have been assuming throughout that semantic values are sets of points of evaluation: they are the kind of thing that, when supplied a world, deliver a truth-value (that's what Figure 17.1 illustrates). Nothing prevents us from using this setup to understand more complicated object languages than we have so far. For instance, we might have an object language that includes recipes and programs.[55] A regular (modal) sentence has a set of worlds as its semantic value because what it says is that things are a certain way. Programs aren't like that. They instead say what they do to ways the world might be: execute it in a world like this, such-and-such results; execute it in a world like that, thus-and-so results. So the denotation of a program is a relation, a set of ordered pairs of worlds (or "states" or whatever the points of evaluation are): the set of ordered pairs such that executing the program in the first member of the pair (possibly) terminates in the second member of

the pair. Dynamic semantic theories can be thought of as theories that say *all* sentences are like that: they are recipes or programs for changing the context or conversational score.[56]

So much for broad brushstrokes. In order to make this concrete we need to decide what aspects of conversational score we care about or what sort of information we want represented in a context. (We will do this in an update semantic framework (à la Veltman, 1996) and follow custom by sometimes calling such bodies of information *information states*.) For us this decision is easy: sets of not-yet-ruled-out possibilities.

Definition 16 (Contexts, information states). A context or information state s is a subset of the set W of possible worlds. I is the set of all such s's.

The limit cases of contexts I (the state of total ignorance) and $\varnothing$ (the absurd state) will have roles to play.

Sentences of our intermediate formal language (that is, propositional logic plus $(\mathit{if}\,\cdot)(\cdot)$) have the same type of semantic value as programs. They are *context change potentials*, relations between information states (actually: functions from states to states).[57]

Definition 17 (Context change potentials (CCPs)). Let a be any atomic formula, p, q be any formulas, and s be any information state. Then the semantic value function $[\cdot]$ is defined as follows:

(i) $s[a] = \{w \in s\colon\ w(a) = 1\}$
(ii) $s[\neg p] = s \setminus s[p]$
(iii) $s[p \wedge q] = s[p][q]$
(iv) $s[(\mathit{if}\,p)(q)] = \{w \in s\colon\ s[p][q] = s[p]\}$

Glossing the machinery for the first three clauses: (i) the change induced by a successful assertion of an atomic sentence is to remove possibilities in which the atom isn't true; (ii) negation corresponds to complementation; and (iii) conjunction is functional composition (the state $s[p]$ is the input for the function $[q]$). All of these represent programs whose purpose is to change the conversational score. The indicative conditional is a different sort of program. It is a *test*: it checks to see if the state $s[p]$ is the same as the state $s[p][q]$. If so, the result is the original s; otherwise, the test fails and the result is $\varnothing$.

This is represented in Figure 17.4 where CCPs are transitions between states. Updating s with $[(\mathit{if}\,p)(q)]$ loops to s iff updating $s[p]$ with $[q]$ loops to $s[p]$. That is the situation in the

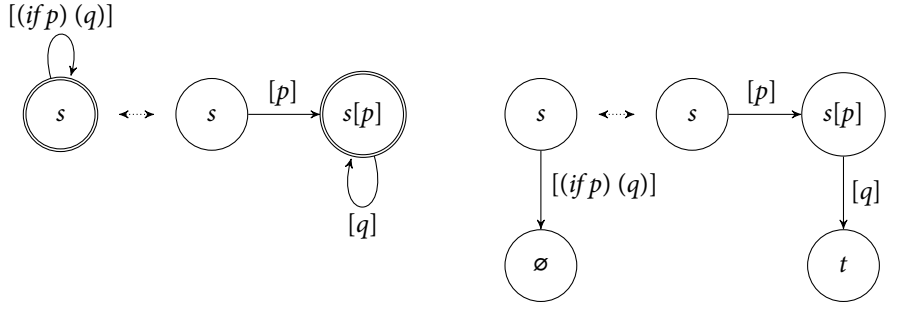

Figure 17.4 Conditional updates: accepted (left) and not (right).

left diagram. On the right: $s[(\mathit{if}\ p)(q)] = \varnothing$ because updating $s[p]$ with $[q]$ adds something new, carrying us to new state t.

This represents a conservative extension of the ordinary semantics of propositional logic.

Fact 21. Let p be any *if*-free formula and s any state. Then: (i) $W[p] = [\![p]\!]$ and (ii) $s[p] = s \cap [\![p]\!]$.

The indicative, though, makes a difference. The way this is often demonstrated is to note that the update function $[\cdot]$ is not, in general, distributive in the sense that it doesn't respect arbitrary unions of its arguments.

Fact 22. It is not in general the case that $s[p] = \bigcup_{w \in s} \{w\}[p]$.

Negated conditionals are a counter-example: updating a state $\{w, v\}$ where $w(a) = w(b) = v(a) = 1$ and $v(b) = 0$ with $\neg(\mathit{if}\ a)(b)$ returns $\{w, v\}$ but updating the singletons $\{w\}$ and $\{v\}$ and collecting the results returns just $\{w\}$.

So indicatives are strict conditionals that invite tests. But when are they true? And what about entailment? Since we are in a richer logical space, we have options. These are reasonable choices: truth is a fixed-point, entailment is so-called *update-to-test* entailment.[58]

Definition 18 (Truth, entailment). For any sentences p, p_i, q and any state s:

(i) p is *true* in s (or s *supports* p) iff $s[p] = s$.
(ii) $p_1, \ldots, p_n \models q$ iff for any s: q is true in $s[p_1] \ldots [p_n]$.

Together with Fact 21, it follows that (for *if*-free p) $s \models p$ iff $s \subseteq [\![p]\!]$. This picture of indicatives is Ramseyan in that the truth of an indicative in a state rides on whether a derived or subordinate sub-state supports the consequent.

Fact 23. An indicative $(\mathit{if}\ p)(q)$ is true in s iff q is true in $s[p]$.

This too can be seen in Figure 17.4 where double-circled nodes represent supporting states.

Collapse arguments highlight the puzzle indicatives pose: they seem to say more than material conditionals but there are no good candidates for what that more is (or worse: it seems impossible for them to say more). The dynamic turn opens up possibilities.

Fact 24. The dynamic conditional together with update-to-test entailment supports *modus ponens* and import/export. Moreover, if p implies q then $(\mathit{if}\ p)(q)$ is true in any state and the $(\mathit{if}\ \cdot)(\cdot)$ is stronger than the corresponding material conditional.

This was a package that collapse arguments led us to believe was not possible.

How does this square with the fact that *modus ponens* plus import/export lead to collapse (Fact 5)? The frameworks are different and so comparisons non-obvious. Let's focus on the conditional-only fragment of the language and (following Gillies, 2009; 2010) retell things

in the context-plus-index-delivers-truth-values setup.

As in §3, contexts deliver sets of possibilities relevant for indicatives. We will again take contexts themselves to be such functions. Here we choose two properties such functions must have.

Definition 19 (Well-behaved contexts). c is well behaved iff for any w:

(i) c is reflexive: $w \in c(w)$;
(ii) c is euclidean: if $v \in c(w)$ then $c(w) \subseteq c(v)$.

The first means that the facts at w are always relevant to the truth of indicative at w. The second means that what is relevant at w is settled. Reflexive and euclidean functions are closed: if $v \in c(w)$ then $c(w) = c(v)$.

The theory here will be a strict conditional theory (different, as we'll see, from the one in Definition 2). So it will say that $(\textit{if}\ p)(q)$ is true at w in c just in case the p-worlds in $c(w)$ are all worlds at which q is true. But true at what context? The Ramseyan subordinate or derived context – write it $c + p$ – got by hypothetically adding the information of the antecedent to c.

Definition 20 (Shifty strict conditional). For any p, q in a well-behaved context c:

$$[\![(\textit{if}\ p)\ (q)]\!]\, c,w = 1 \text{ iff if } v \in c(w) \text{ and } [\![p]\!]\, c,v = 1 \text{ then } [\![q]\!]\ c{+}p,v = 1$$

where $c + p = \lambda w\,.\, c(w) \cap [\![p]\!]c$.

This replicates the dynamic strict conditional.[59] And so there is no collapse. Notice that this puts conditional antecedents to work twice over. They restrict the domain throughout which we check for the consequent's truth. Plain (non-shifty) strict conditionals do this, too. But here antecedents also contribute to the context that is relevant to the interpretation of those consequents. This is the internal dynamics we saw earlier and sets this apart. The shifting is essential. One way to see that: strict conditionals with no shifting can't validate import/export. Another way: earlier we saw that Edgington's master argument against truth-conditions seemed to pit variability against uniformity but that the argument overlooked the possibility that the variability is variability in truth-value at a world across contexts and the uniformity is uniformity across worlds within a context. The context-shifting delivers exactly that. And a third way: we saw that from the point of view of correspondence theory, strict conditionals that support import/export have peculiar selection functions (Fact 4). Not so here: with a context-shifty strict conditional the odd property of "shift coreflexivity" that characterizes one direction of import/export gets replaced by the much more tame property of transitivity.[60]

Let's wrap up this brief foray into the shifty/dynamic strict conditional by looking at one more way the dual roles assigned to antecedents make a difference. The problem that (27) exposes for *if*s that mingle with adverbs of quantification has parallels for *if*s that mingle with (epistemic) modals.

(31) a. If Red isn't in the box, Blue must be.
b. If Blue isn't in the box, Red must be.
c. If there is a marble in the box, it might be Red.

Assume that *must* here expresses a strong necessity epistemic modal $\Box$ over the set of relevant worlds.[61] And assume that *might* is its dual. Then it is surprisingly difficult to say that

if contributes the same iffy meaning to all the examples in (31).

Here's part of the trouble.

(32) Red might be in the box and Blue might be in the box.

This is perfectly compatible with (31a) and (31b). For instance: suppose I know that one and only one of my marbles – Red, Blue – is in the box. But for nearly every p and q the conditionals $(if\ \neg p)(\Box q)$ and $(if\ \neg q)(\Box p)$ aren't jointly compatible with $\Diamond p \wedge \Diamond q$. The restrictor theory has no trouble here.[62]

The broader issue here that parallels what Lewis saw with adverbial quantifiers is that *if*-clauses restrict these modals. But it is hard to see how that restricting can get done by a single conditional operator: one sort of operator might seem reasonable if the operator is a universal like *must* but that same operator looks pretty bad for an existential commingling modal like *might*.[63] This is an issue that shifty/dynamic conditionals handle with ease.

Fact 25. Given Definition 19 and Definition 20:

(i) $(if\ \neg p)(\Box q), (if\ \neg q)(\Box p)$ are jointly compatible with $\Diamond p \wedge \Diamond q$
(ii) $(if\ p)(\Diamond q) \dashv\models \Diamond (p \wedge q)$

These are the same predictions that the restrictor analysis achieves but here *if* still makes a uniform contribution. That is because of the Ramseyan core: the antecedent contributes to the subordinate or derived context that the embedded modal is sensitive to.

9 Other Surveys

No survey of conditionals can be both complete and digestible. This one aimed at the latter property at the expense of the former property and so strategic choices dictated that things which deserve more attention did not get their due. Other surveys – for instance, Bennett (2003), Edgington (1995; 2008), von Fintel (2012a; 2012b), Gillies (2012), Kaufmann and Kaufmann (2015) – make different choices and thus emphasize different parts of the terrain. There are, in addition, more substantial investigations of the logic of conditionals, including Nute (1980) and (especially) Part II of Veltman (1985). A healthy preoccupation with *if*s should be fed a diet rich in just this kind of variety.

Notes

1 Counterfactuals are sometimes called "subjunctive conditionals," but this is an even worse fit. A natural thought: the "subjunctive" marking goes exactly with counterfactuality. Alas, no, as an example from Anderson (1951) shows:

(33) If Jones had taken arsenic, he would have shown just exactly those symptoms which he does in fact show.

A doctor may well use a conditional like this to argue that what afflicts poor Jones is arsenic

poisoning. If counterfactuality means anything like (the speaker is taking it that) the antecedent is false, then the distinctive marking isn't sufficient counterfactuality. Nor is it necessary. In sportscasterese, seemingly run-of-the-mill indicative conditionals are used to convey counterfactual meanings. It's the top of the ninth, the visiting team is down a run but they are down to their last out with a runner – Speedy, as it happens – on second. Slugger hits a double to the gap – surely Speedy should score! – but as Speedy rounds third he trips, falls, and is thrown out. The visitors lose in a shocker. The announcer almost can't believe it. In the aftermath he says:

(34) If Speedy stays on his feet, they probably win the game.

The announcer isn't confused about how the game ended: he's sure Speedy would have scored and Slugger would likely have been hit in, too. See von Fintel 1998 (and the references therein) for the status of the connection between "subjunctive" marking and counterfactuality.

2 There are complications and wrinkles galore. Here are just three, followed by executive decisions about the issues they raise. One: some conditional constructions do not seem to carry conditional information at all.

(35) There are biscuits on the sideboard if you want them. (Austin, 1956)

These are so-called *biscuit* (or relevance) conditionals and are fine things to say but they don't normally (or obviously) express what conditionals normally (or obviously) do. So let's agree to set them aside. Two: there are ways to conventionally express conditional information in natural language without resorting to *if*. This is especially clear with conditional imperatives:

(36) a. Be on time or text me!
b. Keep it up and I'll turn this car around!

These do manage to express some conditional kind of meaning (iffiness but *if* lessness!). Still, set them aside. (While we're at it: we will also not have anything to say about conditional imperatives or conditional questions.) And three: Some languages (apparently) lack lexicalized *if*-constructions altogether. We will largely ignore cross-linguistic pressures, too. The hope is that the executive decisions won't distort things (too much).

3 Though this is a survey, it can't (and won't) pretend to be either exhaustive or unopinionated. See §9 for references that may provide balance on either horn.

4 Whether conditionals in natural language can be represented by a binary conditional connective in a regimented intermediate language is also, as we'll see, up for grabs.

5 Lewis (1980) argued that contexts and indices are both needed and that neither can do the work of the other.

6 For now. Later, when we flirt with various dynamic theories, all we will need to know about them is that they are the kind of thing that *atomic* sentences (of our intermediate language) are true or false at. If an atomic a is true (false) at w, we'll say that $w(a) = 1$ ($w(a) = 0$).

7 So-called because the material conditional is sometimes symbolized by the horseshoe $\supset$.

8 This is Grice's (1975) strategy and is taken up and extended by Lewis (1976). Another pragmatic defense, developed by Jackson (1991), says that when you use an indicative $(if\ p)(q)$, it conventionally implicates that your credence in its truth (that is, the truth of $p \supset q$) conditional on p is high. (Lewis, in the "Postscript" to his 1976, drops the conversational story and instead goes for a slight variant of Jackson's.) There is little independent evidence in favor of this stipulated conventional implicature.

9 *All the beer is gone!* often does not mean that the universe is out of beer but something more modest like the relevant beer supply is out.

10 This discussion follows the discussion in Kaufmann and Kaufmann (2015) and to some extent some of the discussion in van Benthem (2001, §3.2). As we'll see, this provides a modal perspective to Gibbard's (1981) argument that reduces any "propositional" operator meeting a few

minimal assumptions to the material conditional.

11 To see that if $v \in c(w)$ then $v \in c(v)$ implies the right-to-left direction of import/export: assume that $(if\ p)((if\ q)(r))$ is true at w wrt c and consider any $v \in c(w)$ such that $[\![p \wedge q]\!] c,v=1$. (We want to show that $[\![r]\!]\ c,v = 1$ and hence that $(if\ p \wedge q)(r)$ must be true at w wrt c.) Since $[\![(if\ p)((if\ q)(r))]\!] c,w = 1$, it follows that all p-worlds in $c(w)$ are worlds where $(if\ q)(r)$ is true. Hence since $[\![p]\!]\ c,v = 1$, it follows that $[\![(if\ q)(r)]\!]\ c,v = 1$. So all q-worlds in $c(v)$ must be worlds where r is true. Since if $v \in c(w)$ then $v \in c(v)$ and $[\![q]\!]\ c,v = 1$, it thus follows that $[\![r]\!]\ c,v = 1$, as desired. (For the other direction(s): it's generally easier to go by showing how if c isn't constrained (e.g., if it's not in general true that $v \in c(w)$ implies $v \in c(v)$) then you can use the witnessing worlds to counter-example the relevant logical principle. Providing full proofs of these correspondences is left as a rainy-day exercise for the reader.)

12 That is:

(i) *All As are Cs* $\vDash$ *All Bs are Cs* whenever $B \subseteq A$;
(ii) *All As are Bs*, *All Bs are Cs* $\vDash$ *All As are Cs*;
(iii) *All As are Bs* $\vDash$ *All non-Bs are non-As*.

13 Lewis credits Sobel for pointing them out (Sobel, 1970).

14 To be sure: the spatial metaphor here is, in fact, a metaphor. We'll return to this at the end of this section.

15 Sort of. We might go instead with *weak centering* instead of centering: $w \leq_w v$ for every v. This requires that w is always among the closest worlds to w, but allows that other worlds might be equally close. There aren't decisive reasons for favoring weak centering over centering since both deliver *modus ponens* for the counterfactual. Or we might (as Pollock, 1976, does) weaken the ordering assumption by permitting incomparabilities as well as ties in the ordering.

16 Lewis offered this reason against the limit assumption. Take a counterfactual like this:

(37) If Alex had been a little taller, she would have played basketball.

No matter Alex's height, there is no world *closest* to ours in which Alex is just a little taller. Take any world v where Alex's height is h_v where that is a bit taller than her height $h_@$ here. There is another world u such that her height h_u is intermediate. That's just how height works. The argument is not quite decisive, though, since giving up the limit assumption means giving up some pretty desirable features, too. (See, especially, Pollock, 1976; Herzberger, 1979.) And see Swanson (2012) for a discussion of preserving conditional excluded middle without the Limit Assumption.

17 Just what kind of signal? There is a debate. It won't matter too much for us, so set it aside. But see Stalnaker (1975), Veltman (1976), and von Fintel (1998).

18 That is: rendering a conditional determinately true iff if it's true according to each admissible order. Stalnaker (1984) develops this approach in his defense of conditional excluded middle.

19 The famous footnote: "If two people are arguing 'If p, will q?' and are both in doubt as to p, they are adding p hypothetically to their stock of knowledge and arguing on that basis about q…" (Ramsey, 1929/1990, p. 155). The adding this involves can't be feigned or hypothetical belief.

(38) If my students are cheating in class, then I will not discover it (because they're so clever).

The conditional is (let's say) true even though the state I get into by feigning belief in the antecedent won't be one in which I believe the consequent. (Thomason is credited with this observation in van Fraassen, 1980.) The right way to understand augmenting for the Ramsey test is restricting a body of information (my belief state or the contextually relevant information or whatever) by the content of the antecedent. That's different.

20 The (independently developed) classics: Kratzer (1981b) and Veltman (1976), developed and extended in (respectively) Kratzer (1989) and Veltman (2005).

21 A subset P^*_w (also a premise set at w!) of P_w is X-consistent iff $\cap P^*_w \cap X \neq \varnothing$. Such a subset is *maxi-*

mal iff it is contained in no other such subset of P_w.

22 There is nothing in the premise semantics setup that mentions nearness or similarity or anything like that. So to argue that the nearness metaphor in the Lewis–Stalnaker setup has to be more than a metaphor we need an argument that the corresponding premise sets somehow encode (by what is lumped together and what isn't) nearness or similarity information. I don't know what that would look like.

23 One sort of challenge that we won't discuss is whether there is any substantive notion of similarity that plays the role that some versions of the variably strict theory carve out for it. There are different threads one can tug here. One begins with Fine (1975) and (what can be read as) Lewis's (1979a) reply. This thread is neatly discussed in Bennett (2003). Another thread: similarity is the wrong sort of thing. This argument comes from the premise semantics corner (Tichy, 1976; Kratzer, 1989; Veltman, 2005). And a third thread challenges that there can be no such thing as all-in similarity because there is no sensible way of aggregating the comparisons that the relevant theories say must be aggregated (Morreau, 2010).

24 von Fintel (2001) credits Irene Heim with the observation.

25 Lewis saw the loophole in his argument but didn't take it seriously:

> It is still open to say that counterfactuals are vague strict conditionals … and that the vagueness is resolved – the strictness is fixed – by very local context: the antecedent itself. That is not altogether wrong, but it is defeatist. It consigns to the wastebasket of contextually resolved vagueness something much more amenable to systematic analysis than most of the rest of the mess in that wastebasket. (Lewis, 1973, p. 13)

26 The version we will look at says that the meaning of counterfactuals can be factored into the context-changing part of meaning and the content-assigning part of meaning. The version in Gillies (2007) is dynamic all the way, based on an argument that (i) *might*-counterfactuals exhibit the same sort of context-affecting as *would*-counterfactuals with strengthened antecedents and (ii) the only way to accommodate that behavior is by treating the meaning of counterfactuals as their context change potentials.

27 There are a number of equivalent ways of implementing things; in the text, I opt for one that makes use of Lewis-style systems of spheres. A few small points: (i) even though officially what is counterfactually relevant can depend on the world at which we evaluate a counterfactual, since we are going to ignore iterated counterfactuals I'll often drop reference to the world; (ii) I'll treat the default situation as one where only the world of evaluation is counterfactually relevant (rather than a set including it); this is to make comparisons easy to see (for a setup that doesn't go this way see Gillies, 2007, §8); (iii) let's assume (as we have been sometimes doing already) that W is finite.

28 The classic references are Karttunen (1973), Stalnaker (1974), and Lewis (1979b).

29 There is room for refinement here if we want to address the (alleged) dynamics associated with *might*-counterfactuals (Gillies, 2007, §§7–8). That will take us too close to the bleeding edge for today.

30 We have put things in terms of systems of spheres. That was optional since there is an obvious back-and-forth between such a system $c(w)$ centered on w and an ordering $\leq_w$: $u \leq_w v$ iff u belongs to every sphere in $c(w)$ that v does (Lewis, 1973).

31 Note that $c|p|(p \wedge r)| = c|(p \wedge r)|$.

32 Should we deny that indicatives are bound from above by strict implication? I know of no good reason to pursue this.

33 We can't do justice to the literature surrounding McGee-style counter-examples (but see the references in Bennett, 2003, and the more recent discussions in Gillies, 2004; Weatherson, 2009; and Huitink, 2012). Along these lines: there has been some resurgent interest lately in generating "counter-examples" to various principles for conditionals. (See, for instance, Kolodny and MacFarlane, 2010.) I am of the opinion that this is largely a mischaracterization of the issues. For

example: there is no way to say what counts as *modus ponens* without saying what counts as "entailment." And where some might see *modus ponens* failures I'm more inclined to see a poor choice for a story about entailment. A less cryptic version of the point can be found in Gillies (2009).

34 Counter-example: suppose there are just two c-relevant worlds, w and v, where w is a $(\neg p \wedge q)$-world and v is a $(p \wedge \neg q)$-world. Then $p \supset q$ is true at w in c. Since p is compatible with c, the $\leq_w$-minimal p-world must also be compatible with c: so it's v. But since v is a $\neg q$-world, then $(\textit{if}\ p)(q)$ isn't true at w.

35 This runs into some trouble if either p or q is necessary. That's likely a feature of the possible worlds framework as much as a bug of the quasi-Gricean idea here about disjunction, so let's set it aside.

36 Argument: suppose $p \vee q$ is appropriately asserted at w in c. So c has both $(p \wedge \neg q)$-worlds and $(\neg p \wedge q)$-worlds compatible with it. Let c' be the posterior context; it has only $(p \wedge \neg q)$-worlds compatible with it. Let v be any world in c'. The indicative $(\textit{if}\ \neg p)(q)$ requires that the nearest $\neg p$-world(s) to v be compatible with c'. So they must be q-worlds.

37 See Adams (1975), Gibbard (1981), Bradley (2000), Edgington (2008); and Bennett (2003).

38 This is different from the versions of the horseshoe theory in Lewis (1976), Jackson (1991) and Lewis (1986) according to which indicatives have the truth-conditions of material conditionals but which, owing to some pragmatic wrangling, have high (enough) conditional credence as assertability conditions.

39 Stalnaker (2005) tries to narrow the gap between a conditional propositions picture and a conditional assertion picture.

40 There are things that are sometimes said on behalf of the NTV view here (see, for instance, Bennett, 2003) but I don't find them compelling. A more thorough discussion can be found in Gillies (2012).

41 The basic result has been extended and fortified many times over: see, for instance, Lewis (1986), Gärdenfors (1982), and Hájek (1989, 1994) and in the qualitative domain, Gärdenfors (1986) and Segerberg (1989).

42 For those in the know or those returning to this section after we discuss the restrictor theory in §7: the idea there is that when indicatives and probabilistic hedges mix, the correct logical form isn't one of a conditional scoping under (or over) a probability operator. Rather it's a dyadic probability operator whose first argument is the "antecedent" and whose nuclear scope is the "consequent." This idea is advanced in Kratzer (1986; 2012) and resisted in various ways in Rothschild (2012) and von Fintel and Gillies (2014).

43 Dynamic or so-called "context-shifty" accounts, as we'll see in §8, occupy just this spot in logical space. The master argument overlooks this possibility. The connection to Edgington's master argument is discussed in Gillies (2009, §4).

44 Saying that the scoping is $(\textit{if}\ p)(\mathcal{Q}q)$ fares no better.

45 Obligatory quote:

> The *if* of our restrictive *if*-clauses should not be regarded as a sentential connective. It has no meaning apart from the adverb it restricts. The *if* in *always if* …, …, *sometimes if* …, …, and the rest is on a par with the non-connective *and* in *between* … *and* …, with the non-connective *or* in *whether* … *or*, …, or with the non-connective *if* in *the probability that* … *if* …. It serves merely to mark an argument-place in a polyadic construction. (Lewis, 1975)

46 Developed (with some variations) in, e.g., Kratzer (1981; 1986; 1991; 2012).

47 As before, and for the same reasons, the Limit Assumption (or finiteness, take your pick) is in play here.

48 That's no different from the variably strict story where contexts were asked (somewhat implicitly) to supply an ordering of relative similarity $\leq_w$ or a set of premises P_w for each world w.

49 Two questions. What if there is no restrictor (that is, if the modal claim is something like *Alex*

must be there)? Then take the first argument to be your favorite tautology. What if there is no modal at all (that is, if the conditional is a bare conditional like *If Alex is at the party, she is outside*)? Since *if*s restrict, there must be one. So posit a covert necessity operator (a covert *must*).

50 See Gillies (2009) and Khoo (2013).

51 This is a very attractive way out, one hinted at (but somehow not pursued) by Lewis himself when he calls the *if* in *the conditional probability of … if …* a non-connective. It has, however, recently been challenged (Rothschild, 2012; von Fintel and Gillies, 2014).

52 For those familiar with dynamic predicate logic (Groenendijk and Stokhof, 1991): the existential quantifier is externally dynamic since its (semantic) binding power outruns its (syntactic) scope; conjunction, which is relational composition, is internally dynamic.

53 The original idea was inspired (in roughly equal parts) by Ramsey's footnote (1929/1990), the data semantic treatment of indicatives in Part III of Veltman (1985), and the simple update semantics for epistemic modals in Veltman (1996). (The inspiration and divergences, I trust, will be clear.) There is a point to having both implementations available, but we will get to that.

54 There are further refinements, developments, and purposes the dynamic perspective on conditionals can be put to that we won't be able to do justice here. See, for instance, Starr (2014) and Willer (2014).

55 That's what propositional dynamic logic, a particular modal logic, is. A good reference: Harel, Kozen, and Tiuryn (2000).

56 The theories I have most in mind here as exemplars of (classic) dynamic semantic theories are those in Groenendijk and Stokhof (1991) and Veltman (1996). Besides the analogy to the semantics of programming languages (and the empirical coverage they offer), there are other inspirations for the early dynamic turn, especially Karttunen (1973), Stalnaker (1974), and Lewis (1979b).

57 The notation in Definition 17 is post-fix: s is the argument to the function $[p]$.

58 Much of what we know about the landscape here – what options there are, what the properties of those options are – is due to Veltman (1996), van Benthem (1996), and van der Does, Groeneveld, and Veltman (1997).

59 Officially we need to define an entailment relation (Gillies, 2009, §6). The simple case: $p_1, p_2 \vDash q$ iff if $[\![p\ 1]\!]c,w = 1$ and $[\![p\ 2]\!]c{+}p\ 1,w = 1$ then $[\![q]\!]((c{+}p\ 1){+}p\ 2),w = 1$.

60 See Kaufmann and Kaufmann (2015).

61 Each part of this assumption is defensible – that *must* is strong (von Fintel and Gilles, 2010) and that it quantifies over the *if*-relevant worlds (Gillies, 2010, §6).

62 The reply, invariably, is that we should wide-scope the modals. This turns out to force a choice between giving up a link between *if* s and *must*s:

(39) If Alex is here, Billy is here ≈ If Alex is here, Billy must be here.

and giving up a link between *if* s and *might*s:

(40) If Alex is here, Billy might be here ≈ It might be that Alex and Billy are here.

The restrictor theory doesn't have to give up either. This is discussed in Gillies (2010, §6).

63 Lewis admitted that the restricting was after all possible with a "far-fetched" interpretation of the conditional – the one defended in Belnap (1970) that says that $(if\ p)(q)$ is true at w if the confirming instance is true, false if the counter-example is true, and undefined if p is either false or undefined at w. The idea has been revived and extended to be fit with modals (von Fintel, 2007; Huitink, 2009). It is problematic, though, since it seems to be saddled with the prediction that indicatives presuppose (entail, actually) their antecedents. That seems a distance from what conditional information is all about. (See also the discussion of this in von Fintel, 2012a, §5.2.)

Generics

BERNHARD NICKEL

Generics (a linguistic phenomenon) exhibit genericity (not obviously a linguistic phenomenon), and though a theory of generics is closely connected to a theory of genericity, the two are distinct. They raise a host of interesting linguistic and philosophical issues, both separately and in their interaction.

1 Generics

Let's begin with a fairly manifest phenomenon we can observe in natural language. There is a range of sentences that, speaking intuitively, we can use to talk about kinds. The clearest examples are sentences that predicate properties that only kinds can have (what we may call *kind-restricted predicates*).

(1) Ravens are widespread.
(2) Dodos are extinct.
(3) Diamonds are rare.

Individual ravens can't be widespread; individual dodos can only be dead; and individual diamonds are all, by their very nature, unique.[1] Since (1)–(3) concern kinds – *genera* – the claims themselves have come to be called generics.

In addition to describing a kind using kind-restricted predicates, we can also characterize it, or perhaps characterize its members *qua* members of that kind, by using properties that individuals can have. We can call these latter generics *characterizing* generics. (4)–(12) are some true characterizing generics.

(4) Ravens are black.
(5) Tigers have stripes.
(6) Coke bottles have short necks.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

(7) Bishops move along diagonals.
(8) Lions have manes.
(9) Lions give birth to live young.
(10) Lions have four legs.
(11) Sea turtles are long-lived.
(12) Barns are red.[2]

We can contrast them with (13)–(17), which are false.

(13) Ravens are white.
(14) Prime numbers are odd.
(15) Supreme Court Justices have odd Social Security Numbers.
(16) Green bottles have short necks.
(17) Sea turtles die young.

As these examples indicate, a lot of our knowledge of the world is most naturally expressed using generic sentences. Generic sentences are also an important component of the language young children hear as they mature ("motherese").[3] For that reason, a semantic theory for natural language needs to have an account of generics.

These examples share several more specific features – beyond the intuitive sense that they are closely connected to kinds – that have made them of interest to philosophers and linguists alike, and these specific features support the intuitive sense that generics are particularly closely concerned with kinds.

1.1 Statistical Variability

There is no simple statistical criterion that systematically tracks the truth or falsity of characterizing generics. If we wanted to formulate a statistical criterion, the intuitive sense that generics characterize the kind at issue would suggest the hypothesis that they are universal generalizations. But empirically, that hypothesis is a non-starter, since most generics are compatible with a range of non-conforming cases. (4) and (5) are true in the face of albino ravens and tigers, respectively, while the truth of (8) tolerates the existence of female and immature male lions, and that of (11) the fact that a great many sea turtles are eaten by predators before they reach old age. A more plausible hypothesis holds that a generic is true if and only if most members of the kind have the property at issue. This hypothesis seems to be quite successful at capturing the intuitive force of (4) and (5), but it founders on examples like (11), since these are true even though most turtles die very shortly after birth, and on combinations like (8) and (9), since at most one of the males or females can be in the majority.

In response, we might further weaken the analysis of generics to require only that *some* members of the kind have the property at issue in order for the generic to be true, that is, analyze generics as existentials. This weak analysis is compatible with the truth of all of the examples (4)–(12), but it goes too far. It falsely predicts that *ravens are white* and *sea turtles are short-lived* are both true. For that reason, there is no single, simple statistical condition that successfully distinguishes true from false generics.[4] Even worse, a statistical approach just seems to be on the wrong track entirely when we consider generics that reflect rules such as (7). The truth of such a generic shouldn't be hostage to how often people happen to move bishops in some other way than along diagonals, be it in jest, out of carelessness, or for any number of intuitively irrelevant reasons.

1.2 Interlude: Generics and Context Dependence

In arguing that there's no simple statistical criterion that systematically captures the patterns of the truth and falsity of generics, I've so far ignored the possibility of invoking context-dependence. Yet it is well-known that many, and perhaps all, explicitly quantified statements are context sensitive. In different situations, they quantify over different domains. One might therefore wonder whether the problems generics raise dissipate as soon as we allow ourselves to draw on mechanisms of context sensitivity in interpreting generic sentences, which after all seem to express some sort of generality.

The problem does not dissipate so quickly. Even if generics are context sensitive, they are not context sensitive in the same way as explicitly quantified sentences. One salient difference concerns the features of the context that can influence the interpretation of the two sorts of sentences. Making a restriction extremely salient does not *ipso facto* influence the interpretation of generics as it does that of explicit quantifiers.[5]

Circus The lion act involves fierce lions that have to be restrained with chair and whip. The bear act involves bears riding unicycles and dancing.

(18) The bears are tame. (True)

(19) Bears are tame. (False)

So if we want to draw on mechanisms of context sensitivity as part of a theory of genericity, we must do so in a way that takes account of the distinctive features of genericity. I'll return to this issue throughout the chapter.

1.3 Modal Import

Generics seem to not just be substantially independent of statistical facts in the world and at the time with respect to which they are evaluated. They also seem to have implications for worlds or times beyond. We can see this by noting that some generics are false even though all members of the kind conform to the generalization, while others are true even though no members of the kind conform. A famous example of the first sort is (15): even if it is true that all Supreme Court Justices conform to (15), we still do not take it to be true. And the situation does not change if we know that no further Supreme Court Justices will be appointed, perhaps because the institution will be abolished when the next Justice steps down. There is no stronger statistical condition than that all members of a collection have the property predicated, so more than just the statistical facts that obtain at the world and time with respect to which (15) is evaluated must be relevant to its truth.

On the flipside, we find certain generics to be true even though no members of the kind conform to them. A standard example is (10). Not only is (10) true, it would still be true even if every single lion were to have some number of legs other than four, perhaps by some combination of mutation, accident, combat, and the machinations of a madman. But of course the truth of (10) in such a situation cannot be accounted for simply by suggesting that generics are equivalent to universal generalizations and that the universal generalization *all lions have four legs* is vacuously true. That would make *lions have seventeen legs* true as well. So more than just what is true at the world and time with respect to which (10) is evaluated must be relevant to its truth. These two examples illustrate the *modal import* of generics.

1.4 Well-Established Kinds

The sense that generics are peculiarly concerned with kinds is also sometimes supported by pointing to the contrast between (6) and (16), between *Coke bottles have short necks* and *green bottles have short necks*. While the former has a clear meaning and is indeed true, the latter is decidedly odd. This contrast is then explained by suggesting that generics can only concern well-established kinds, and that the green bottles fall short of constituting such a well-established kind.

I doubt, however, that this can be the right explanation for the contrast, since there are many generics that are clearly true but which do not concern kinds that can possibly count as more well-established than the green bottles. Consider (20).

(20) (Some true generics not about kinds)
   a. Albino ravens are white.
   b. Calico cats are female.

So some other account of the contrast is required, and it remains to be seen whether that contrast supports the sense that generics are closely concerned with kinds or whether it is simply an epiphenomenon.

In light of these observations, we should say that generics reflect an intimate connection between a property and a kind *or collection*, the connection that obtains when the property is characteristic of the kind or *collection*. But for ease of exposition, I'll continue to simply speak of generics as concerning kinds, taking it as read that they can also concern (at least some) non-kind collections.

Before moving on, let me emphasize that these theoretically interesting features are not meant as *tests* for genericity. Sentences that we have every reason to expect to be generics might not exhibit one or more of these features. An easy example is (21).

(21) Lions are mammals.

While the initial examples could at least potentially have counter-instances – members of the kind that do not have the property predicated in the generic – (21) could not. Presumably that is not due to some special feature of the semantic interpretation of generics, but rather to the fact that the characteristic connection happens to hold between a property and a kind that are also related by necessity.

2 Genericity

As can be seen from this list of theoretically important features of generics, the theoretically most central cases are characterizing generics, even though generics that predicate kind-restricted properties are the most obviously kind-directed forms of speech. For that reason, let's call *genericity* the phenomenon exhibited by characterizing generics: there is a particularly close or intimate connection between a kind and a property, one that does not obviously coincide with either statistical notions (all, most, many, some), nor does it coincide with well-established modal notions (necessity or essence). Let's call this connection *characteristic*.

Just about all theories of generics are, in the first instance, theories of genericity. They are a theory of the characteristic connection between a property and a kind that we see

expressed by characterizing generics. Since the meaning and use of generics is probably the most direct evidential connection we have to genericity, it's only natural to frame a theory of genericity as a theory of the truth-conditions of generics.

However, it's useful to separate generics from genericity, at least conceptually. We can see this by looking more closely at their relationship.

3 Separating the Semantics of Generics from Theories of Genericity

3.1 The Syntax–Semantics Interface

As a first point, we should note that there is no straightforward correlation between syntactic properties of a sentence and whether it can be used as a generic. All of the sentences that, in English, can express genericity, can also be used to express something non-generic.

The three forms of sentences that can be used as characterizing generics are bare plurals, singular definites, and singular indefinites. The basic paradigm is given in (22)–(24).

(22) Ravens are black.
(23) The raven is black.
(24) A raven is black.

Contrast these uses of the sentences as generics with their non-generic counterparts (25)–(27).

(25) Ravens are sitting on my lawn.
(26) The raven took the carrot.
(27) A raven scratched the post last night.

(25) and (27) are simply existential, (26) is about a particular bird.

There are some slight but striking differences among the different sentences we can use as generics. The singular definite suggests a stricter connection between property and kind, as the contrast between (28) and (29) indicates.

(28) Dutchmen are good sailors.
(29) The Dutchman is a good sailor.

(28) was first proposed in the *Port Royal Logic* of 1663.[6] At that time, it would certainly have been true to say it, even though (29) might have struck us as too strong.

(24) also has a stronger flavor than the bare plural (22). What is more, while both the bare plural and the singular definite happily combine with kind-restricted predicates, the singular indefinite does not, as (30) and (31) witness.

(30) *A raven is widespread.
(31) A raven is extinct.

(30) is simply impossible, while (31) is acceptable, but only has a reading that differs from its minimal counterpart *ravens are extinct*: the former can only mean that a subspecies of ravens has gone extinct, not that the whole species has. A semantic theory for generics needs to explain how these differences in the meaning of generics arises, but we probably won't learn much of interest about *genericity* from that.

The importance of separating generics and genericity comes out even more clearly when we look at one of the most prevalent arguments in discussions of genericity, arguments about the logical form of generics.

3.2 The LF of Generics

Let's call the kind of representation of a sentence that contains all of the information required for the interpretation of a sentence the LF of that sentence, where the expression 'LF' is supposed to be reminiscent of the notion of a logical form.[7] While sentences with more than one quantifier are ambiguous with respect to their scope, the LFs of such a sentence are unambiguous, to give just one example.

Two Options: Quantificational and Kind-Predicating Analyses

There are two camps that all accounts of the LF of generics fall into, and proponents of both camps model the LF of generics on that of other kinds of sentences. One camp looks to quantifiers as the crucial model, the other to referring expressions such as proper names. These hypotheses have a lot of empirical content because on either one, we immediately predict that generics are subject to the constraints that apply to the kinds of sentences they are modeled on, be that model quantificational or referential. These are predictions we can test, and they point to problems that proponents of either camp have to overcome in order to arrive at a more persuasive theory.

On a quantificational approach to generics, these sentences lack a quantifier only in so far as no quantifier is pronounced or written down. The LF of these sentences contains a quantificational element that has a distinctively generic meaning but is otherwise just like other quantificational expressions. The quantificational approach comes in two flavors, corresponding to two main ways that quantification is expressed in English. One models the generic quantificational element in a sentence such as (32a) on quantifiers such as *all* in (32b).

(32) a. Ravens are black.
b. All ravens are black.
c. Ravens are always black.

This determiner version of the generic operator is defended by some theorists.[8] An alternative version of the generic operator is defended by more, this one modeled on adverbs of quantification, such as *always*, *sometimes*, and *mostly*, illustrated in (32c).[9]

The second main approach to the LF of generics analogizes them to referring expressions. It is certainly the minority position.[10] It's motivated in the first place by drawing on the analogy between sentences in which a property is predicated of an object and sentences in which a kind-restricted property is predicated of a kind, an analogy exhibited in (33) and (34).

(33) Mary is home.
(34) Diamonds are rare.

Since being rare can only coherently be predicated of kinds, it seems extremely plausible that *diamonds* in (34) refers to a kind, just like *Mary* in (33) refers to a person. But then the null-hypothesis should be that *diamonds* uniformly refers to the kind, even in characterizing generics such as (35).

(35) Diamonds are valuable.

In addition to considerations of theoretical simplicity, proponents of the kind-predicating approach usually cite the problems the quantificational approach has as the main evidence in favor of their position.

Arguments that Turn on Scope

One famous argument turns on the scope possibilities generic sentences exhibit. Consider (36)–(38).

(36) Jane believes that some professors are eccentric.
  a. … just on general principle.
  b. … even though she doesn't know they're professors.
(37) Jane believes that Alice is eccentric.
(38) Jane believes that professors are eccentric.

When an ordinary quantified sentence is embedded in a propositional attitude verb such as *believes*, it can usually be interpreted in two ways. On the narrow scope interpretation, the ascription requires that the subject of the attitude, Jane in this case, has a general, quantified thought, and that she makes use of the concept picked out by the quantifier, *some professors* in this case. This reading is made prominent by the continuation (36a), which suggests that there aren't any particular professors Jane has in mind, she just thinks that there are some eccentric ones. On another reading, made prominent by the continuation (36b), Jane believes of some specific people that they are eccentric, and we as onlookers ascribing the belief to Jane make use of the notion of a professor, though Jane need not. This latter reading is apt when Jane meets what are in fact eccentric professors at an event without knowing that they are professors, but whom she quickly identifies as eccentric. The first reading is called the *narrow scope reading*, because it results from interpreting the quantified expression within the scope of *believes*, much as the sentence is actually sounded. The latter reading is the *wide scope reading*, since it corresponds roughly to *some professors are such that Jane believes them to be eccentric*.

There is no corresponding ambiguity in the interpretation of referring expressions that occur in the scope of propositional attitude verbs. (37) only has one reading, on which there is a specific person that Jane has in mind, though perhaps Jane thinks of the person in a different way. Generics seem to pattern with referring expressions, rather than quantified expressions, in this respect. (38) does not seem to be ambiguous. It can only mean that Jane believes the kind constituted by professors to be characterized by eccentricity. That suggests that (38) is associated with an LF on which *professors* refers to a kind, since we then predict the similarity in available and unavailable readings between (37) and (38).

The situation isn't completely univocal. Proponents of the quantificational analysis have offered the rejoinder that there *are* scope ambiguities with generics. Three important examples are (39)–(41).[11]

(39) Storks have a favorite nesting area.
  a. … which other storks try to capture.
  b. … which is in my backyard.
(40) John intentionally put belladonnas into the fruit salad because he mistook them for cherries.
(41) Typhoons arise in this part of the Pacific.

(39) has two readings, each of which we can bring to prominence with a suitable continuation. (39a) is apt if *a favorite nesting area* has narrow scope with respect to *storks*, (39b) if it has wide scope. (40) is intended to show that bare plurals can take wide scope with respect to propositional attitude ascriptions. Suppose that John is not trying to harm the people for whom he prepared the fruit salad, and keep in mind that belladonnas are poisonous. In that case, it cannot be part of his intention to put belladonnas in the salad. Rather, the intention was to put these things, which were in fact belladonnas but which John mistook for ordinary cherries, into the salad. And that proposition is expressed only if *belladonnas* takes wide scope with respect to the propositional attitude predicate *put intentionally*.[12] Finally, on a kind-referring strategy, we miss a possible reading of (41). On that strategy, the sentence is taken to mean that it is characteristic for typhoons to arise in this part of the Pacific. Typhoons arising elsewhere is an exceptional circumstance. But the much more prominent reading is that it's characteristic of this part of the Pacific that typhoons arise there, though typhoons arise in other parts of the world, as well.

This second set of examples suggests that the interpretive options for generics more closely mirror those of quantified sentences, not those of referential ones. The scope-taking characteristics of generics are thus equivocal, some pointing towards a kind-predicating analysis, some to a quantificational analysis. To resolve this issue, we need to look to further evidence. But we can already see the sorts of considerations that bear on the LF of generic sentences: they all concern whether positing one or another sort of LF for generics allows us to capture systematic constraints on interpretation.

This point becomes clearer still once we look at the most important challenges to a quantificational analysis of generics, which turn on how conjunctions work in generics.

Arguments that Turn on Conjunctions

Conjunctions raise several related problems for quantificational theories. The usual conclusion drawn from these problems is that only kind-predicating can meet the challenge. The purpose of this section is to articulate the challenge.

The first challenge, and one that is discussed quite frequently, centers on generics in which a property of kinds and a predicate of individual members of a kind are conjoined.[13] Consider (42) and (43).

(42) Diamonds are rare.
(43) Diamonds are valuable.

On a kind-predicating analysis, both sentences have structurally identical LFs, differing only in the predicate, given in (44) and (45), respectively.

(44) [diamonds rare]
(45) [diamonds valuable]

In both, *diamonds* denotes the kind, and both attribute a property to that kind. Using a semi-formal notation to mirror the LFs as much as possible, we can give the truth-conditions of (42) and (43) as (46) and (47), respectively.[14]

(46) $R(d)$
(47) $V_G(d)$

The predicate in (47) is subscripted to indicate that it is one that felicitously applies to kinds and is true just in case the kind is characterized by being valuable. Consider now the conjunction (48).

(48) Diamonds are rare and valuable.

The LF of this sentence is just like those of (42) and (43), except that the predicate now has more internal structure. Using the bracket notation, we can describe the LF as (49).

(49) [diamonds [rare and valuable]]

This LF is unproblematically interpretable, since the verb-phrase simply consists of a complex expression denoting a similarly complex property of kinds. We can state the predicted truth-conditions in a way that reflects this fact about the interpretability of (49) by making use of the notion of a conjoined predicate, as in (50).[15]

(50) $[R \wedge V_G](d)$

Here, $R \wedge V_G$ is a predicate true of a kind just in case that kind is both rare and characterized by being valuable.

Things appear differently for quantificational views. On a quantificational view, the initial examples (42) and (43) have very different LFs. The former predicates a property of the kind as a whole, so that we can simply retain the LF (44). But the LF of (43) is more complex.[16] For definiteness, assume that the generic operator *gen* occupies the same position as explicit quantifiers like *all* or *some*. The LF of (43) is thus (51).

(51) [[*gen* diamonds] [are valuable]]

To mimic the LF in a statement of the truth-conditions, we can give (52) as the output of the compositional system for (51).[17]

(52) [GEN x: $D(x)$]($V(x)$)

For all that I have said here, the truth-conditions (52), as predicted by the quantificational view, might be completely equivalent to the truth-conditions (47) as predicted by the kind-predicating view in the sense that they are true in all the same worlds. The crucial difference between the two views is how the truth-conditions are arrived at.

We should highlight a fact about quantificational LFs such as the one in (51). Like all generalized quantifiers, the generic operator has a restrictor and a scope, and the content of these two components is determined *structurally*, that is, the content of these two components is determined as a function of the syntactic structure of the LF of the sentence we're interpreting. The sister of the generic operator provides the restrictor, and the VP provides its scope.[18]

With this commitment in mind, consider how one can analyze the conjoined generic (48) on a quantificational approach. Obviously, there are two options: it can be given an LF that does not contain a generic operator, instantiating the same structure as (49), or it can be given an LF that *does* contain a generic operator, given in (53).

(53) [[*gen* diamonds] [rare and valuable]]

But on a quantificational approach to generics, neither LF gives rise to the proper interpretation. (49) is just uninterpretable, since according to it, a complex predicate is predicated of a kind-denoting expression, but that complex predicate does not pick out a property of kinds, because *valuable* does not pick out a property of kinds.[19]

The alternative LF (53) is no better, since it predicts that the sentence has the truth-conditions (54).

(54) $[\text{GEN}\, x\text{: } D(x)](R(x) \wedge V(x))$

That is to say, it requires that generically many diamonds are, each individually, both rare and valuable. And just as *valuable* cannot coherently be predicated of kinds, so *rare* cannot be predicated of non-kinds. Either way, (48) is predicted to be no good. But in point of fact, it is true. So quantificational approaches to generics must be rejected.

In giving this argument, I assumed for definiteness that the generic operator *gen* appears in the same position as quantificational expressions like *all* or *some*. Once this assumption is made, it follows from the basic structure of the sentence that the verb-phrase expresses a single complex condition, either by expressing a complex predicate that is predicated of the kind, as in (49), or by expressing a complex condition that is mapped to the scope of the generic quantifier and that individual members of the kind have to satisfy, as in (53). Opting for the alternative that the generic operator occupies not the position of a quantificational determiner such as *all* or *some*, but of an adverb of quantification such as *usually* or *normally*, does not change the argument substantially. For on this way of implementing the quantificational approach, it is still true that the whole VP expresses a single, complex condition that individual members of the kind need to meet. This argument against quantificational views of generics only relies on the basic architecture of the sentence. The argument requires no assumptions about how to interpret a generic operator. Therein lies its great strength.

But one might also think that combinations like *rare and valuable* are themselves quite rare and thus perhaps should not force quantificational theorists to abandon their position very quickly. Exceptional cases can perhaps be treated on an *ad hoc* basis. For this reason, I want to now look at another problem conjunctions raise, one which relies on slightly stronger assumptions about quantificational approaches to generics. These assumptions show the problem to be absolutely ubiquitous.

Conjunctions with More Complex Scope

This argument requires a bit more of a windup. Let me give you an intuitive statement first. An ordinary characterizing generic, such as *ravens are black*, divides the members of the kind into at least two categories (and if it's false, three). There are the members of the kind that the generic is *about* in some very rough sense, in this case, the black ravens that, so to speak, come by their blackness in the ordinary way (not ravens that are born as albinos and then dyed). There are the members of the kind that the generic is *not about*, such as the albinos. Those are the members that we feel are irrelevant when we're evaluating the truth of a generic.

What's more, different generics about one and the same kind divide the kind up in different ways. Consider (55).

(55) a. Ravens have two wings.
b. Ravens have two legs.

Still speaking intuitively, ravens that have lost a leg by accident, predation, or what have you, support the truth of (55a) just as much as ravens with two legs, so long as they have two wings. Ravens that have lost a wing by accident, predation, or what have you, support the truth of (55b) just as much as ravens with two wings, so long as they have two legs. These two generics, then, carve up the kind in different ways. But now consider (56).

(56) Ravens have two legs and two wings.

On a quantificational approach, (56) has an LF that predicts the following truth-conditions for it: generically many ravens have the complex property of having two legs and two wings. And in that case, the conjunction (56) is about fewer ravens than either of its conjuncts. In the case of (56), this may not be too bad. But consider (57).

(57) a. Lions have manes.
b. Lions give birth to live young.
c. Lions have manes and give birth to live young.
d. Lions have manes and lions give birth to live young.

(57a) excludes, *inter alia*, all of the female lions. (57b) excludes, *inter alia*, all of the male lions. On the quantificational approach, it would appear, (57c) therefore excludes all of the male *and* all of the female lions, that is, all of the lions. Yet there is clearly a reading of (57c) on which it says no more or less than (57d), the simple conjunction of (57a) and (57b).

Let me articulate this dialectic somewhat more precisely. In doing so, we'll have a chance to observe a fact about generics that is important in its own right: that they are inferentially inert in various ways. In fact, we can begin right there.

Even if it's true that, necessarily, all *Fs* are *Gs*, it still doesn't follow from the fact that *As are F* that *As are G*. A famous example of this inferential failure is the following.

Chicken Failure

(i) Chickens lay eggs.
(ii) Necessarily, all chickens that lay eggs are hens.
∴ (iii) Chickens are hens.

Yet on a quantificational approach, we'd expect that the inference is valid so long as the generic quantifier is upward entailing in its nuclear scope, an assumption all implementations of a quantificational approach accept. For illustration, assume that the generic quantifier means "all normal." In that case, premise (i) would mean that all normal chickens lay eggs; by premise (ii), that would entail that all normal chickens are hens. And that is just the interpretation of the conclusion (iii).

The standard response to this problem concerning inference is to suggest that the restriction of the generic quantifier depends on the predicate at issue, and perhaps on the context, so that different restrictions are at issue in the premise (i) and conclusion (iii). Just to give an example, if we thought that generics were about normal members of a kind, then on this revision, different notions or perhaps respects of normality would be at issue in premise and conclusion.[20]

The inferential profile of generics requires us therefore to posit different restrictors for the generic operator, depending on the predicate in the nuclear scope. With this in mind, return to an example I mentioned before, repeated here.

(58) Lions have manes and give birth to live young.

If we posit a generic quantifier that occupied either the position of a determiner, analogous to *all*, or an adverb of quantification, analogous to *always*, we would predict that all of these sentences only have interpretations that are clearly inappropriate, either because they are

false, or because they don't coincide with our intuitive sense of their meaning. The reason for this prediction lies in the very fact that already raised the trouble in interpreting (48): the whole predicate is interpreted as expressing a single, conjoined condition the kind is supposed to be characterized by. Hence, (58) is interpreted as expressing the proposition that generically many lions both have manes and give birth to live young, or put in terms of normality, that all normal lions have manes and give birth to live young. But such lions are extremely *ab*normal. This is the only reading a quantificational account seems to be able to assign to (58), and it therefore misses its most natural reading, one that is well paraphrased by *lions have manes and lions give birth to live young*.

I find these arguments the most powerful ones about the LF of generic sentences, far more than the inconclusive ones relating to scope I reviewed before. The data here are completely univocal.[21]

Before moving on, I want to point out a likely form of context dependence in generics. We have already seen that on a quantificational approach to generics, the restrictor of the generic quantifier must be determined at least in part by the predicate at issue. That was the lesson of the CHICKEN FAILURE. But that is probably insufficient to account for some contrasts, such as the one exhibited in (59).

(59) a. Bears ride on unicycles.
b. Bears ride in train cars.

Some semantic theories of generics predict that the predicates in (59a) and (59b) determine the same restriction of the generic quantifier, since both are concerned with locomotion. Such theories might appeal to context to determine a more fine-grained restriction, perhaps distinguishing between locomotion that is part of entertainment and locomotion that is part of transportation.

3.3 Separating the LF of Generics from Theories of Genericity

I have spent a great deal of time arguing about whether quantificational approaches to generics are correct. I now want to argue that the issue of whether a quantificational or kind-predicating approach is correct is orthogonal to the central issues raised by the phenomenon of genericity. Among these is perhaps the most basic: whether it's possible at all to give an informative account of genericity in the first place.

It's important to be clear on this because if there was a direct connection, we could investigate metaphysical questions with distinctively semantic means, since the arguments concerning the linguistic analysis of generic sentences invoke facts that are metaphysically neutral, such as scope possibilities and the interpretive options for conjunctions. The line of argument I have in mind begins with an analogy with explicit quantificational expressions. Consider a simple, universally quantified sentence, such as (60).

(60) All ravens are black.

The truth of that sentence supervenes in an obvious way on facts about individual ravens. (60) is true just in case every raven, perhaps in some contextually restricted range, is black (I'll ignore the contextual restriction from now on). The sentence is obviously quantificational, containing an element that denotes universal quantification, to wit, *all*. And when we give the compositional semantics for (60), we also give an informative analysis of that quantificational element, for example in terms of Tarski's semantics

for quantification. Indeed, the analysis of (60) that is part of the compositional semantics for English *just is* a description of the relationship between a collection and a property distinctive of universally quantified sentences: all members of the collection must have the property at issue.

Likewise, if generics are analyzed quantificationally, they contain an element that denotes generic quantification: *gen*. But then we also need to give it a semantics, and these semantics need to tell us how the truth of a generic about a kind depends on facts about individual members of that kind. If that's right, then at least the following holds: if we are skeptical of the possibility of giving an informative theory of genericity, then we're *ipso facto* skeptical of the possibility of stating the semantics of *gen*. But without a semantics, *gen* cannot make a systematic contribution to the meaning of sentences in which it appears, and hence generics don't have proper meanings on a quantificational approach to their interpretation. Hence, such skepticism should move us to accept that the interpretation of generics is kind-referring, not quantificational.[22]

However, drawing this sort of inference is not at all obligatory. Positing an element in the LF of a sentence is one thing. Being able to offer an informative analysis of that element is another. Indeed, drawing such a distinction is inescapable in the context of semantics as I've presented it here, since the point of this sort of semantics is to describe a relation between elements with a meaning that is taken as primitively understood – words, to a good first approximation – and elements with a meaning that is determined by them – paradigmatically sentences.

The point is perhaps most easily appreciated by considering simple predicates, such as *being a spy*. If I want to represent the semantically relevant information of the sentence *Lucy is a spy*, I will, *inter alia*, make use of a predicate *spy*. As far as the interpretation of that sentence is concerned, that is all that the occurrence of *spy* contributes. In the semantic interpretation, *spy* is then assigned an extension, perhaps the set of spies. As a separate matter, we may also believe that being a spy isn't the sort of property that floats freely in the metaphysics of the world. Rather, there's an informative theory of what makes someone a spy to be given. But whether or not there is such a non-trivial theory of spyhood is simply irrelevant to the question whether our LF representation is accurate or not. As far as the systematic description of the meaning of sentences containing that predicate is concerned, we can and perhaps should take it as primitively understood.[23]

The upshot of the discussion so far is that metaphysical issues about genericity and semantic issues about generics are independent in one direction. Denying the possibility of an informative theory of genericity is compatible with adopting either a quantificational or a kind-predicating LF for generics.

The independence holds in the other direction, as well. Accepting the possibility of giving such a theory of genericity is also compatible with adopting either sort of LF. The argument is straightforward. Suppose that we have a theory of genericity. This can be part of a semantic theory for a generic quantifier, precisely parallel to the semantics of the universal quantifier. But if it turns out that from the perspective of available readings and so on, generics behave as if they made reference to kinds, then the LF of generics should be kind-referring, and the theory of genericity is simply a non-semantic analysis of what characterizing a kind amounts to in exactly the same way that a theory of spyhood is a non-semantic analysis of what being a spy amounts to. Hence, there is no straightforward substantive connection between debates about the LF of generics and the possibility of describing genericity generally and informatively.

4 Connecting the Semantics of Generics with Theories of Genericity

I have argued that there is no direct connection between a linguistic semantic theory of generics and a broadly metaphysical theory of genericity. But that is not to say that there is no connection at all. There are many important ones.

In the first instance, our use of generic sentences is our best and most direct evidence for what genericity is like, and constructing a semantic theory of generics will help us to distinguish good from bad evidence in the usual way in so far as we'll be able to say more explicitly and precisely how much of our use of generics reflects the semantic content of generics and how much is a pragmatic accretion. In this respect, generics are exactly like all other phenomena where our intuitions about the world, as expressed in language, provide us with evidence for our theorizing.

But in the second instance, a semantic theory for generics plays a more distinctive role, as well. Genericity is, as I've been at pains to emphasize, a theoretical notion. We introduce it by reflecting on various phenomena, such as statistical variability and modal import, and positing a common, unifying explanation for these phenomena. But then we can also ask which phenomena, exactly, need to be accounted for by a theory of genericity. Once again, let me consider a particular example in order to make the issue vivid, (28), repeated here.

(28) Dutchmen are good sailors.

How can we fit the interpretation of (28) into a more general account of generics?

Set aside for the nonce the choice of formal tools and approach we want to bring to bear on our analysis of generics. Let's focus only on the intuition a formal treatment could be designed to capture. The most popular and prominent examples of characterizing generics, those that initially shape a lot of theories, are (61)–(63).

(62) Ravens are black.
(62) Tigers have stripes.
(63) Lions have manes.

These examples suggest that the characteristic connection between property and kind is a somehow close or intimate one.

But this motivating intuition seems to be undermined by the fact that there are some generics where it seems incredibly implausible that there could be a close connection between belonging to a kind and the property predicated in the generic. (28) is just such an example. Even at a time when the Dutch had a maritime empire it didn't seem as if there was anything that made the very good sailors particularly good examples of being Dutch. (64) is another example of the same type.

(64) Ravens are bigger than toasters.

It just seems odd to think that there's anything about being a raven that puts ravens in a close relationship to properties of toasters. They certainly aren't selected for being bigger than toasters (no toasters under conditions of selection) nor are toasters part of raven ecology today.

There thus seems to be a real tension, simply at the level of motivating intuitions. On the one hand, the examples (61)–(63) suggest that genericity is a close or intimate connection,

an intuition further supported by the modal import we've already noted. On the other hand, (28) and (64) suggest that the connection can be quite loose, and certainly not essential-ish in the way suggested by the previous examples. How should we respond to this sort of tension?

We could deny that (28) needs to fit into a theory based on the guiding intuition that characteristic connections are close connections. Perhaps generics are simply ambiguous, with one interpretation being exemplified by *ravens are black*, another by *Dutchmen are good sailors*. Such a denial could take the form of an appeal to context sensitivity, in this case, contextual variation in the sort of relationship that is said to hold between a property and a kind.

Consider, for example, generics from the contested and controversial realm of politics. Based on the high statistical correlation between being a kindergarten teacher and being a woman, a speaker who holds strong biological determinist views may assert (65) to express these views.

(65) Kindergarten teachers are women.

However, another speaker might also point out that there are various social factors, including upbringing, discrimination, and so on, that bring it about that many women are steered towards less prestigious and less well-paid professions. At the same time, certain professions, including kindergarten and preschool teacher, are perceived as "women's work," and hence paid relatively little. So it is far from an accident that the statistical fact – that the vast majority of kindergarten and preschool teachers are women – obtains. Against this background, an opponent of the sorts of injustice I just mentioned may also wish to assert (65) to mark out precisely that there is a very strong and important connection between being a kindergarten teacher and being a woman, albeit one that is external to the individual agents involved, and one that we should oppose.[24] Two speakers who disagree about the underlying social, political, and biological facts may thus convey very different propositions with the same generic. The question for such an invocation of context-dependence is whether it can be sufficiently constrained so as to avoid making it too easy for generics to be true.[25]

A second way to respond to the initially puzzling cases (28) and (64) suggests that the initial intuition that generics are always about a very close, almost essential, connection between property and kind, was mistaken. In some cases in which the characteristic connection holds, an intimate or quasi-essential connection holds as well, as is perhaps the case in the motivating examples, but that does not make the characteristic connection the quasi-essential one. Here, too, the threat of over-generation lurks.

A third option is easier to see for (64). It may turn out that the apparently problematic fact is nothing more than an interaction effect between genericity and other, semantically significants features of the generic sentences involved.

In the case of (64), the problem arises because the sentence appears to predicate *being bigger than toasters* of the kind raven and hence claims that this property is the characteristic one. But that may be mistaken. An alternative linguistic analysis of the sentence holds this: ravens have a certain characteristic size, toasters have a certain characteristic size, and the former size is greater than the latter. In that case, what's characteristic of ravens is not a relation to toasters, but simply having a certain size. And there may well be a close or intimate connection between ravens and their characteristic size.

So the construction of a semantic theory of generics is almost certainly an important part of coming to a satisfactory account of genericity, but how the two are related must be determined on a case-by-case basis.

5 Ascriptions of Dispositions, Habits, and Capacities

I have so far suggested that we should, at least conceptually, distinguish between generics and genericity, and that genericity can manifest itself when we assert or think that there is a characteristic connection between a property and a kind. A natural question is whether genericity is exhausted by this characteristic connection.

The matter is unclear. Consider another linguistic phenomenon that appears to share many of the theoretically important features we noted in re: characterizing generics. These are ascriptions of dispositions, habits, and capacities, examples of which are given in (66).

(66) a. Jane drinks coffee. (habit)
b. My Peugeot goes 120 mph. (capacity)
c. This glass breaks when struck. (disposition)

There are many similarities between these ascriptions and the generics I've been discussing so far that justify treating them all as belonging to a single class. In an ascription of a habit, disposition, or capacity – a *habitual* for short – we take a property that is most directly true of something at a specific time, such as drinking right here and now, being driven at 120 mph yesterday morning from eight to nine, or breaking when the glass was struck last week, and we ascribe that property to objects in a less direct way, so that the predicate can be true of the object even while the object isn't actively engaged in, say, drinking, running, or breaking. We thus have a parallel to the intuitive sense of "moving up" in category that we see when we take a property true in the first instance of objects and ascribe it to a kind made up of that sort of object.

Just like characterizing generics, ascriptions of habits, capacities, and dispositions exhibit an independence from the particular situations with respect to which they are evaluated. They can be true, even if the object to which they are ascribed never exhibits the property ascribed, as in the famous (67).

(67) Mary sorts the mail from Antarctica.

It may be true that sorting Antarctic mail is Mary's job, in which case (67) is true, even if no mail ever arrives from Antarctica and Mary perforce never sorts any such mail.

In light of these similarities, it is certainly plausible to think that habituals and characterizing generics are both manifestations of the same underlying phenomenon, that is, that genericity can manifest itself both in our thought and talk about characteristic connections, and in our thought and talk about dispositions and so on.

Regardless of whether we want to give a uniform account of characterizing generics and ascriptions of dispositions, habits, and capacities, another question arises. What is the relationship between ascriptions of dispositions and habits, which seem to exhibit some sort of genericity, and ascriptions of dispositions that do not make use of generics, such as *the glass is fragile*? It may be possible, for example, to analyze all ascriptions of dispositions in terms of generics.[26] The answer to this question is currently a matter of debate.

6 Some Theories of Genericity

To give a sense of the theoretical options available, I will briefly review four approaches to generics and genericity.

6.1 Is There a Logic of Generics?

In order to frame the discussion, I have treated genericity as a more or less metaphysical notion – genericity is something that manifests itself in the characteristic connection between a property and a kind. But in the first instance, one may think that genericity is an aspect of our thought and talk, so that it is a feature of the objects of our beliefs and assertions. It's therefore an open possibility that genericity should be understood less as a feature of the world, and more as a feature of how we use language in making our way around the world. One such approach analyzes generics in terms of their logic.

We have already seen that generics don't enter into deductive relations with other generics in connection with the failed inference concerning chickens. A generic sentence doesn't validly entail anything about individual members of a kind. By way of illustration, we may observe that the following inference is invalid, since Tweety might be a penguin.

Tweety Inference

(i) Bids fly.
(ii) Tweety is a bird.
∴ (iii) Tweety flies.

Further, we cannot validly conclude anything about supersets or subsets from the truth of a given generic, as illustrated by (68) and (69).

(68) Baby giraffes have short necks.
⇏ Giraffes have short necks.
(69) Lions have manes.
⇏ Female lions have manes.

The former shows that we cannot generally draw an inference from a subset to a superset, the latter that we cannot generally draw an inference from a superset to a subset. There therefore aren't any distinctively generic, fully general deductively valid inferential patterns.

Now, while the Tweety inference isn't valid, it isn't completely terrible either. In very many circumstances, the conclusion receives a lot of support from the premises, although a speaker or thinker may be forced to withdraw the conclusion if she acquires further information, for example, that Tweety is a penguin. Nonetheless, it does seem that it's acceptable to provisionally draw the Tweety inference until such extra information becomes available.

A formal treatment of such provisional inferences is given by non-monotonic logics: suppose we have an inference relation $\vdash$ that relates sets of sentences and sentences. The logic characterized by $\vdash$ is *non-monotonic* just in case the following generalization fails for at least some set of sentences Γ and sentences φ, ψ: if $\Gamma \vdash \varphi$ then $\Gamma \cup \psi \vdash \varphi$. Informally: adding premises to a good inference does not make it bad.

One may hold that certain non-monotonic inferences exhaust the meaning of generic sentences. This is the non-monotonic analogy to the idea that certain deductive inferences are constitutive of the meaning of the logical constants. The meaning of conjunction is exhausted by pointing to the inferences it underwrites, *and*-introduction and *and*-elimination. Likewise, the meaning of the generic *ravens are black* is completely captured by the fact that a speaker who accepts it is licensed to infer that something is black if she learns that it's a raven, and she has no information to the contrary that defeats the inference.[27]

A central question for such an approach concerns just what counts as additional information that may defeat the inference. The problem arises most clearly for generics that are true, even though only a minority of members of the kind conform to it. Consider (70).

(70) Sea turtles are long-lived.

Assume, as is indeed the case, that most sea turtles die young. Should we treat this knowledge as defeating the default inference that Sandy is long-lived, knowing only that Sandy is a sea turtle? On the one hand, the usual gloss of knowledge that defeats an inference is knowledge that is specific to the case at hand, such as that Tweety is a penguin. On the other hand, the information that most sea turtles die young is additional information that goes beyond the generic sentence itself.[28]

6.2 Probabilistic/Majority-Based Approaches

An approach to theorizing about genericity that has a similar starting point but divorces it from actual inferences focuses on probabilities. It is due to the work of Ariel Cohen (1999a; 1999b; 2003; 2004). Cohen's account is an interesting example of a theory that is designed to account for various important features of generics by positing an interaction between a compositional semantic theory for generics and a non-semantic, metaphysical theory of genericity, couched in terms of probability.

Most abstractly, he suggests that a characterizing proposition is true just in case *most* members of the relevant kind *in a suitable domain* have the property at issue. For Cohen, all of the work thus takes the form of specifying the suitable domain in a general and informative way.

We can see these two components – majorities and the suitability of the domain – in action by seeing how Cohen's semantics account for some basic data.

(71) a. Ravens are black.
b. Ravens are white.

On Cohen's view, (71a) is true just in case the probability that a randomly chosen raven is black is greater than even. Within Cohen's system, that is equivalent to the claim that most ravens in a suitable reference class are black. Assuming for now that all of the ravens that exist form a suitable reference class, Cohen's view correctly predicts that (71a) is true. Likewise, (71b) requires that most ravens in that class are white. Since that is not the case, Cohen's view correctly predicts that (71b) is false.

Of course, if we simply consider the distribution of a property among members of a kind at the world and time of evaluation, generics are predicted to be susceptible to what are intuitively irrelevant accidents. Cohen handles these sorts of blips by taking a suitably long view of the matter. Though at a moment the actual frequency with which a property is instantiated in a population might vary widely, over time that frequency will tend towards a more stable value. It is the stable, long-term value that is relevant to the evaluation of a generic, not the potentially fluctuating short-term value.

We now have the raw materials of Cohen's view, but not quite the whole semantics, since the materials I've introduced so far aren't quite sufficient to account for examples such as (72).

(72) a. Lions have manes.
b. Lions give birth to live young.

Cohen diagnoses the reason that the examples in (72) are true as the result of restricting our attention to a proper subset of the members of a kind. He accomplishes that restriction by introducing alternatives: whenever a generic predicates a property of a kind, we have to interpret that generic with a range of implicitly given alternatives to the property actually predicated. In the case of (72a), these alternatives are properties such as having colorful tail-feathers, having large antlers, and other forms of sexually selected ornamentation; in the case of (72b), the alternatives include giving birth by laying eggs, by cell division, and so on. When we evaluate a generic, we only look at those members of a kind that satisfy at least one of the alternatives. In (72a), that has the effect of excluding all of the females and immature males from consideration, since they don't have any forms of sexually selected ornamentation; in (72b), it has the effect of excluding males and infertile females, since they don't reproduce by any means. Among the remaining members of the kind, it is indeed the case that most members conform to the generalization, so that (72a) and (72b) are correctly predicted to be true.

To summarize, we can state Cohen's truth-conditions for generic sentences.[29]

(73) Let [GEN x: $A(x)$]($F(x)$) be a sentence, where A and F are properties. Let ALT(F) be the set of alternatives to F. Then
[GEN x: $A(x)$]($F(x)$) is true iff $P(F|A \wedge \vee \text{ALT}(F)) > 0.5$

In words: *As are F* is true just in case, in a suitable set of *A*s, all of which have at least one of the alternatives to *F*, most are *F*.

These truth-conditions show the interaction between non-generic semantic facts, specifically, the provision of a set of alternatives that are modeled on the interpretation of focus, and a theory of genericity, which is reflected in the majority-based quantification and in the specification of a suitable domain.

6.3 *Cognitive Approaches*

A very different idea is embodied in cognitive approaches which take generics to quite directly reflect aspects of our cognitive system. These include theories according to which generics reflect stereotypes (e.g., Declerck, 1986; Geurts, 1985) and approaches on which they reflect conceptual connections (e.g., Prasada and Dillingham, 2006; 2009). One central question for such approaches concerns how to handle generics that don't concern lexicalized concepts, that is, generics that concern collections that do not form a kind and that do not plausibly have associated stereotypes, such as (74) and (75).

(74) Cats with blue eyes are usually blind.
(75) Whoopee cushions left on stuffy professors' chairs on Friday afternoons are funny.

It also seems as if such cognitive approaches can be too divorced from the world. Consider a baseless stereotype. How can we ensure that the corresponding generic comes out false, rather than true?

An interesting development of a cognitive view that avoids some of these problems has been presented by Sarah-Jane Leslie (2008). On her view, some generics track relatively objective facts about the world, others much more subjective ones. *Ravens are black*, for example, tracks the fact that we take there to be characteristic sorts of properties that organisms have, including coloration, and black is the characteristic color for ravens. Other generics simply reflect that certain facts are deeply impressive to us as subjects in the world,

including shark attacks and the transmission of viruses by mosquitos, which is why *sharks attack bathers* and *mosquitos carry the West Nile Virus* are true. The central question for an account like this is whether the psychological facts really do coincide with the truth-conditions of generics: is it the case, for instance, that every fact in the world that is striking, dangerous, or otherwise impressive is also honored with a corresponding generic?

Cognitive approaches to generics generally, and Leslie's work in particular, raise a host of foundational questions about the relationship between semantics and human cognition. Leslie argues for her theory, for example, on the grounds that it fits more naturally with observations about language acquisition, a source of evidence semantic theories usually do not consider. Her work also suggests that the sorts of patterns that are usually considered as best accounted for with the tools of formal semantics are perhaps better handled by appeal to more idiosyncratic aspects of human psychology.

6.4 Normality-Based Approaches

A fourth family of views takes its inspiration from the intuition that generics are about what is normal. The intuition can be brought out most clearly, perhaps, by considering how we respond to members of a kind that do not conform to a given generic we accept as true. Confronted with an albino raven, we might say that, at least as far as *ravens are black* is concerned, the albino is abnormal. That response suggests that generics are about what is normally the case.[30] The key questions for such an account are twofold: What is the target of normality, and how can the notion of normality be spelled out substantively.

The first question concerns the choice whether we should interpret generics in terms of normal worlds, or in terms of a more fine-grained notion, such as normal individuals. As we saw in section §1, generics have modal import, so the theoretically most natural treatment of generics would be to interpret them in terms of normal worlds, perhaps using different notions of normality in different contexts. An initial implementation of such an approach would interpret a generic *As are F* as true iff in all most normal worlds, all *A*s are *F*. Unfortunately, this approach faces significant problems. To give a flavor of the concern, return to *sea turtles are long-lived*. A world in which all sea turtles are long-lived is a world in which sea turtles aren't subject to predation. But that is, speaking intuitively, not a biologically normal world.

A more natural approach may look towards a more fine-grained notion of normality, perhaps looking at normal members of a kind. This raises the second key question for normality-based approaches: What does it mean to be normal, given that it is not a statistical notion? What makes this question particularly vexing is that generics cover a very broad range of phenomena, including the natural world, the social world, rules of games (*bishops move along diagonals*), to name just a few. The question is whether it's possible to describe a notion of normality that is rich enough to explain why, for example, albino ravens aren't normal when we evaluate *ravens are black*, while being flexible enough to apply across all domains.

7 Two Ways of Doing Away with Genericity

I have been speaking of theories of genericity, assuming that genericity is a phenomenon in its own right. This assumption can be questioned, and I want to look at two different ways of doing away with it.

7.1 Falsity and Pragmatics

One might think of generics as very widespread instances of *loose talk*, a notion that has been described by Lasersohn (1999). And if generics really are instances of loose talk, the variability we see in their interpretation does not reflect a theoretically unified phenomenon of genericity – it reflects a hodgepodge of incredibly localized, pragmatic factors that aren't susceptible to systematic theorizing. To assess the merits of this concern, let me begin by introducing the notion of loose talk.

Consider an assertion of (76).

(76) Mary arrived at 3:00 p.m.

In very many circumstances, we're happy to accept the sentence – to not critique the speaker on the grounds that she has said something false – even if Mary didn't arrive at 3:00 p.m. on the dot, but only at a few minutes before or after 3:00. One way of theoretically describing what's going on holds that, though the sentence is false in such a situation, it conveys a truth because we were speaking somewhat loosely. The reason to think that the sentence is actually false but only conveys something true is that, when conjoined with the tolerated slack in the situations we'd accept as being described by a use of that sentence, we get a contradiction. *Vide* (77).

(77) Mary arrived at 3:00 p.m., though she arrived at 3:05 p.m.

More generally, instances of loose talk are cases in which a sentence is used that is false when evaluated with respect to a given circumstance, but where the context is such that the aspects of the situation that account for the sentence's falsity can be acceptably ignored.

An extension of these ideas into a treatment of generics may appear attractive. Consider, for example, the exchange (78).

(78) A: Birds fly.
B: What about penguins?
A: # Birds fly.

A's simple repetition in this exchange is odd, and this oddity is easily accounted for if generics were simply instances of loose talk. On this strategy, generics have the same truth-conditions as the corresponding universal generalizations, but the bare plural indicates that we are speaking somewhat loosely. *A*'s initial assertion is thus false – it is false that all birds fly – but it might nonetheless be unobjectionable if the flightless birds can be ignored. *B*'s question, and its concomitant introduction of penguins into the conversation, makes it so that they cannot be ignored any longer. Hence, the falsity of *A*'s second utterance can no longer be overlooked.

Appeals to loose talk also promise straightforward accounts of the very vexing examples that make arriving at a substantial theory of genericity so difficult. After all, it might make sense to ignore a vast number of members of a kind if they're all uniformly irrelevant. Hence, *sea turtles are long-lived* is handled easily. The sentence is false, but in most situations in which we care about the lifespan of sea turtles, we're ignoring what happens to them immediately after hatching. We only care about the ones that have made it to the pet store.

If (uses of) generics really are instances of loose talk, then there is no such thing as genericity. There is no single, underlying phenomenon that accounts for the properties of interest of generics across a wide range of cases. Rather, what we can ignore in a context

given our other aims and interests is just about guaranteed to be a sundry and miscellaneous mess, since the aims and interests we bring to different contexts are sundry and miscellaneous, precisely not the manifestation of a single, theoretically coherent phenomenon.

Happily for the prospects of an informative semantics for generics, the loose talk conception is not really tenable. For one, we've seen that a key reason to identify a use of a particular sentence as an instance of loose talk comes from the felt contradictoriness of conjoining that sentence with an explicit acknowledgment of the kind of looseness we're willing to tolerate. To make the point maximally vivid, it it useful to switch to another of Lasersohn's examples. He points out that we are often willing to accept (79) even though not quite all of the townspeople are asleep.

(79) The townspeople are asleep.

We might, for example, plan to raid the town, and we're happy to accept the sentence so long as we can legitimately ignore those townspeople who are still awake – perhaps the awake ones won't foil our plans. Now consider the contrast between (80) and (81).

(80) # The townspeople are asleep, though some townspeople are awake.
(81) Ravens are black, though some ravens are white.

The former is far worse than the latter. In fact, (81) is perfectly acceptable. That strongly suggests that generic sentences are true. We can see the same point by contrasting how loose talk interacts with negation. In an instance of loose talk, the sentence used is false, so that negating it yields a truth. Here too, loose talk and uses of generic sentences differ markedly.

(82) Mary didn't arrive at 3:00 p.m.
  a. …, she arrived at 3:05 p.m.
(83) Ravens aren't black.
  a. …, some ravens are white.

If Mary really arrived at 3:05, then (82) is perfectly acceptable, though perhaps pedantic. But (83) is clearly bad, even given the analogous continuation in (83a). Furthermore, the loose talk conception of generics can make no sense of the fact that some generics strike us as false even though the corresponding universal generalization is both true and acceptable, such as *Supreme Court Justices have odd Social Security Numbers*. For on the loose talk conception, that just means that the generic is true, as well. Our use of generics isn't simply an instance of loose talk.

7.2 Thoroughgoing Context Sensitivity

We have seen throughout this chapter that generics are context sensitive in several distinctive ways. Their domain appears to be restricted, albeit through different mechanisms than ordinary quantified sentences. One such mechanism may involve a restriction of the domain as a function of the predicate, as shown by the CHICKEN FAILURE and related phenomena. We have also seen that, at least in some cases, it may be plausible that which connection is said to hold by a generic can be sensitive to context, as may happen when discussing politically and socially contested generics.

One can take the existence of these forms of context-dependence as an indication that generics are thoroughgoingly context sensitive. Indeed, one could even claim that all of the facts that we initially took as manifestations of a single, underlying phenomenon, genericity,

are better explained as many different manifestations of context-dependence. This might be the case if, as Sterken (2015) has argued, the very force of the quantification involved in generics is determined by context. On such a view, it's not just that context determines a way for us to restrict our attention, as in *all contextually salient As are F*. Instead, context determines what sort of quantification we're countenancing, as in *Q many As are F*. On such a view, distinctive context-dependence is all there is to genericity. The key question is whether such an approach offers a more systematic account of generics than one that leans more heavily on a mix of semantics and metaphysics.

8 Closing

Writing in 2016, we can say that the study of generics is still in its very early stages. Fundamental questions are left open: Which phenomena should be treated together? Which separately? Which framework or frameworks are most promising?

Philosophers and linguists are also just beginning to investigate the possibilities of drawing on genericity as an explanatory notion in other arenas. In philosophy, that includes debates about dispositions, about the nature and status of *ceteris paribus* laws in the special sciences, the nature and resistance to countervailing evidence of stereotypes, and the normative domain, to name just a few.

Notes

1 One may well want to avoid complicating one's ontology by positing kinds in addition to other abstract objects such as properties. To do so, one could interpret predicates such as *widespread*, *extinct*, and *rare* as properties of the properties of being a raven, a dodo, and a diamond, respectively. However, this strategy leaves unexplained why the following sentence is infelicitous, not just false: *the students in this class are extinct*. Why can *extinct* be predicated of the property of being a dodo but not of the property of being a student in this class? The same point also shows that we cannot simply analyze such kind predication as collective predication. Predicates such as *be from different countries* are similar to kind-predicates in that they cannot be predicated of individuals. However, as the example I just gave shows, kind-predicates are much more selective than collective predicates, which suggests that they apply to a special range of objects: kinds.

2 This may strike some readers as an odd example, since redness is not anywhere near as intimately connected to barns as blackness is to ravens. But it is a widely attested generic, and examples like this are important data points for theories of generics and genericity. They challenge theories that attempt to account for the meaning of generics too directly in terms of an intimate or close connection between kind and property.

3 See, e.g., Gelman (2003).

4 I qualify this conclusion to only apply to "simple" statistical conditions since we'll see a more complex statistical account in discussing Ariel Cohen's (§6.2). His account is not so easily refuted.

5 This sort of case is reported in Krifka *et al.* (1995, p. 45). As with everything connected to generics, the facts are not univocal, as the following contrast illustrates.

(A) # Rooms are square.
(B) (Traditional Japanese architecture has strict rules.) Rooms are square.

While (A) is odd, in part because it is a claim about rooms generally, the context set up by (B) manages to restrict the interpretation of *rooms* to rooms that follow the rules of traditional Japanese architecture (cf. Greenberg, 2003, p. 36).

6 Arnauld and Nicole (1996/1683).
7 Nonetheless, I don't call it a logical form, because LFs in this context are a term of art that may well diverge from the thing or things philosophers call logical forms in other contexts.
8 See, e.g., Asher and Morreau (1995).
9 Lewis (1973) is the basic text in the contemporary study of adverbs of quantification. Cohen (1999a; 1999b), Schubert and Pelletier (1989), and Wilkinson (1991) are some of the theorists who treat generics on this model.
10 This view is most famously associated with Greg Carlson's dissertation (Carlson, 1977) and has recently been defended by Liebesman (2011).
11 (39) is from Schubert and Pelletier (1987), (40) from Kratzer (1980), and (41) from Milsark (1974).
12 A potentially confusing fact about the argumentation surrounding (40) is that *belladonnas* must be given an existential reading, rather than a generic, on a par with *ravens are sitting on the telephone wires*, which means that there are some ravens sitting on the wires, not that it's characteristic of ravens to sit there. But this difference between generic and existential interpretations is irrelevant for the debate about kind-referring and quantificational LFs for generics, since on the kind-referring strategy, *all* uses of bare plurals are kind-referring, be they existential or generic. Thus, showing that existential bare plurals do not behave as predicted on the kind-referring strategy simultaneously undermines the kind-predicating strategy for generic uses of bare plurals.
13 These examples were already urged in favor of a kind-predicating analysis in Carlson's dissertation (1977), and they have since been endorsed by Schubert and Pelletier (1987) and, very recently, Liebesman (2011).
14 Notice, however, that what's crucial *isn't* some particular way of stating the truth-conditions of these sentences. The issue turns on *how* the truth-conditions are assigned, specifically, on the LF that serves as the input to the compositional semantic machinery. Thus, the point of this specification of the truth-conditions is just to give a sense of the LFs involved.
15 To ease exposition, I couch the discussion of the compositional semantics in as informal terms as possible. In particular, I eschew λ-notation as much as possible. In that notation, the predicate would be $\lambda x\,.\,\left[R(x) \wedge V\,G(x)\right]$.
16 It's a further issue how the two kinds of LF are related. Perhaps generics are simply ambiguous, and one of the readings is ruled out on pragmatic grounds. Alternatively, one of the LFs might be basic and the second is generated in response to uninterpretability. For the second view, see Cohen (2001).
17 I'll use GEN, an expression in the metalanguage, as the interpretation of *gen*, a silent operator that is part of the object language.
18 Once we take into account further phenomena, such as focus, mapping the material in a sentence into restrictor and scope becomes harder, but for now, we can retain the simple hypothesis.
19 What exactly goes wrong may differ from one particular implementation to another. Perhaps the VP is uninterpretable because of a type-mismatch. Perhaps the VP is somehow interpretable, but then the sentence as a whole is ill-formed because of a mismatch between part of the meaning of the VP and the subject. The details don't matter to the argument.
20 In a quantificational setting, Asher and Morreau (1995), Cohen (1999a; 1999b), and Nickel (2008) have proposed similar theories. Gerstner-Link (1988) and ter Meulen (1986) offer a similar strategy in the context of interpreting generics as modalized conditionals. Finally, the idea that restrictions imposed by the predicated property are theoretically important is also present in the circumscription approach due to McCarthy (1980; 1986).
21 For some recent discussion, see Leslie (2015), and Nickel (2016).
22 This line of thinking is quite explicit in Carlson's dissertation (Carlson, 1977) which set the framework for most further theorizing about generics (Carlson, 1977, p. 73).
23 One theorist who I think is best interpreted in these terms is Sarah-Jane Leslie, especially her (2008). This is the contrast Leslie has in mind when she distinguishes the truth-conditions of a generic (a semantic notion) from worldly truth-makers (a metaphysical notion).

24 Cf. Haslanger (2012).
25 I will return to this point in §7.2, when I discuss ways of eliminating genericity.
26 Cf. Fara (2005).
27 In a dynamic setting, Veltman (1996) is a good discussion. In a completely different framework, Brandom (1994) is an instance of this strategy.
28 For some recent work on the connection between generics and default inference, see Pelletier (2010) and Pelletier and Elio (2005).
29 Adapted from Cohen (1999b, p. 37).
30 See, for example, Asher and Morreau (1995), Eckardt (1999), Nickel (2008; 2016) and Schurz (2001).

Deflationist Theories of Truth, Meaning, and Content

STEPHEN SCHIFFER

I

When a philosopher proposes a semantic theory she commends for being deflationist,[1] that theory is intended to replace an entrenched theory that is predicated in part on what is thought to be the need to answer certain questions, and the philosopher objects to that theory not because it gives the wrong answers to those questions, but because she feels those questions are the wrong ones to be asked by a theory seeking to explain what the entrenched theory might legitimately hope to explain. Her alternative theory, she contends, is both to be preferred to the entrenched theory and deflationist relative to it because it doesn't bear the burden of needing to answer those questions.

Every deflationist semantic theory has its inflationist correlate: this is the semantic theory the deflationist theory is designed to deflate. Consequently, distinct deflationist semantic theories may differ from one another either by having different inflationist correlates or by having the same inflationist correlate but differing in their views of how its deflating should go. Some deflationist semantic theories are considerably more deflationist than others. For example, a deflationist theory of truth as applied to propositions needn't be at all deflationist about semantic notions in their application to sentences or utterances. The most interesting deflationist theories would be ones that are deflationist about all semantic notions in all their applications; but of such theories I am aware of only one. I'll call this theory *Radical Deflationism*, and I'll take its inflationist correlate to be a theory I'll call *Radical Inflationism*, although it will be obvious that there are a number of inflationist alternatives to Radical Deflationism that are less inflationist than Radical Inflationism. I shall present Radical Inflationism and Radical Deflationism as stipulatively defined theories, without regard to who might subscribe to them, or to one or another of their parts, but, as will become clear as I proceed, Radical Deflationism is based on a view worked out over a number of important publications by Hartry Field.[2] This chapter is mostly structured around a discussion of Radical Deflationism, but Part II briefly discusses another way of being semantically deflationist.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

A. Radical Inflationism

The radical inflationist doesn't doubt that there are semantic and propositional-attitude facts, and she holds that semantic and propositional-attitude predicates such as 'means,' 'is true,' 'refers to,' 'is true of,' 'believes that,' and so on both apply contingently to the things to which they apply and are univocally applicable both interlinguistically and interpersonally. For example, she holds that the properties ascribed by the italicized predicates in

- 'Brutus killed Caesar' (as used by English speakers) *means that Brutus killed Caesar*
- 'Brutus killed Caesar' (as used by English speakers) *is true*
- 'Brutus' (as used by English speakers) *refers to Brutus*
- 'Killed' (as used by English speakers) *is true of Brutus and Caesar (in that order)*
- I *believe that Brutus killed Caesar*

are exactly the same as the properties they ascribe in

- 'Брут убил Цезаря' (as used by Russian speakers) *means that Brutus killed Caesar*
- 'Брут убил Цезаря' (as used by Russian speakers) *is true*
- 'Убил' (as used by Russian speakers) *is true of Brutus and Caesar (in that order)*
- Vladimir *believes that Brutus killed Caesar*.

She also holds, first, that semantic and propositional-attitude facts play indispensable causal-explanatory roles in explaining how we are able to use the utterances and beliefs of others as a source of information about the world, and in predicting and explaining human behavior, and second, that, because they play those causal-explanatory roles, our semantic and propositional-attitude notions must be explicable in terms of physically realizable functional or causal notions. In other words, the radical inflationist is on board with the view Hartry Field had when he wrote "Tarski's theory of truth," that our notions of reference and truth are correspondence notions that stand in need of physicalistic explications (Field, 1972).

It's not difficult to see the path that might lead a radical inflationist to the other extreme, the view I'm soon to call Radical Deflationism. First, she is apt to find that it proves "extraordinarily difficult to develop the details of an adequate correspondence theory" (Field, 1986, p. 67) – that is to say, extremely difficult to find plausible naturalistic explications of our semantic and propositional-attitude notions. Second, as we are about to see, Radical Deflationism avoids the need to find physicalistically acceptable underpinnings of any kind for our semantic and propositional-attitude notions, and the frustrated radical inflationist is apt to find very strong appeal in "the prospect of avoiding the need to work out the details of [a physicalistically acceptable explication of our semantic and propositional-attitude notions], by declaring that [the interpersonally applicable semantic and propositional-attitude notions she thought were in need of physicalistic explication] serve no very important purpose" (Field, 1986, p. 67). And third, while the appeal of that prospect wouldn't carry much weight for a radical inflationist unless she had reason to doubt whether the intentional notions in question served any very important purpose, she is apt to give credibility to Radical Deflationism's claim that it's "extremely difficult to find a persuasive argument" (Field, 1986, p. 67) that we *need* the semantic and propositional-attitude notions that define Radical Inflationism.

B. Radical Deflationism

In presenting Radical Deflationism it's advisable to proceed in stages. This is because the theory takes as its core semantic notions certain egocentric use-independent disquotational notions, but those notions aren't themselves able to do all that the radical deflationist thinks semantic notions are needed to do, so the theorist finds it necessary to define certain non-egocentric semantic notions in terms of those core notions. Consequently, I propose to conceptualize Radical Deflationism as developing in six stages. Each stage will have the radical deflationist *stipulatively define* the semantic and propositional-attitude notions he takes himself to need at that stage, until by the end of the sixth stage he has all the intentional notions needed to do what, by his lights, semantic and propositional-attitude notions are needed to do. At that point he will leave open the question of to what extent his stipulatively defined notions might serve to explicate the intentional notions we actually use, for, while he doesn't rule out that his notions might do a passable job of capturing what is legitimate in their ordinary-language counterparts, he has little-to-no interest in accounting for the use of 'means,' 'true,' 'believes,' and so on in ordinary language, a question he regards as being "of only sociological interest" (Field, 1994a, p. 133). His primary interest in the notions that are to define Radical Deflationism is to determine whether they can do the work we might legitimately expect intentional notions to do, thereby showing we have no *need* for inflationist semantic or propositional-attitude notions.

Stage One: Unambiguous Eternal Sentences

Let's pretend for a while that every sentence of *my* language is an unambiguous eternal sentence[3] that, unlike 'This sentence isn't true,' doesn't give rise to any liar-like antinomy. The predicates to be introduced at this stage are 'means_{ss},' 'true_{ss},' 'false_{ss},' 'refers_{ss},' and 'true-of_{ss}.' I intend the stipulations by which I will introduce them to make these predicates (nearly enough) what Field (in the works cited) would call "purely disquotational." The 'ss' subscript indicates that the subscripted predicates apply to all and only the expressions I "understand," as I "understand" them, where this implies, for example, that "if on my understanding of 'Der Schnee ist weiss' it is equivalent to '$E = mc^2$,' then for me this sentence is [true_{ss}] iff $E = mc^2$" (Field, 1994a, p. 134). I have 'understand' in scare quotes to indicate that the word is not being used as it's used in ordinary language, and certainly not as the radical inflationist would use it. On that, the inflationist use, for a person to understand an expression is for her to use, or to know how to use, it *correctly*, so that, for example, if I use 'Exercise is enervating' the way you use 'Exercise is energizing,' then I have used it incorrectly and thus *mis*understand it. But for the radical deflationist there is nothing to count as my misunderstanding an expression that has a use in my idiolect; if I use 'Exercise is enervating' the same way I use 'Exercise is energizing,' then that just shows that my understanding of the one sentence is the same as my understanding of the other. What the radical deflationist means by 'understanding a sentence' is roughly as follows. Assume that I think in a language of thought, which may be the same as the language I speak (whatever exactly that is taken to mean), and let's continue to pretend that the languages with which we are at this point concerned are ones all of whose sentences are unambiguous and eternal. Whether or not my mentalese is a neural version of my spoken language, every spoken sentence of mine will, relative to our simplifying assumptions, be uniquely correlated with a mentalese sentence whose conceptual role is the conceptual role my spoken sentence would have if my

spoken language were my language of thought, where a sentence's conceptual role is the role the sentence has in my perceptual belief formation and in my theoretical and practical reasoning. A sentence's conceptual role is determined by the conceptual roles of its syntactic structure and constituent morphemes, and those conceptual roles are the contributions those things make to the conceptual roles of the sentences in which they occur. A mentalese sentence may be prevented from playing its conceptual role if for example it's too long or convoluted for one to process owing to the computational limitations of one's brain. If we ignore those limitations, however, we can say, as for convenience I will say, that, for the radical deflationist, my understanding of a sentence just is the conceptual role of its mentalese correlate. If, consequently, the mentalese correlates of my sentences 'Exercise is enervating' and 'Exercise is energizing' have the same conceptual role, then no invidious comparison can be made between my understanding of the two sentences; they merely happen to be the same.

The stipulations that define Radical Deflationism at this first stage are as follows.

'*Means*$_{ss}$' applies only to expressions I understand, and every instance of the schema

'*S*' means$_{ss}$ that *S*

(e.g., '"Snow is white" means$_{ss}$ that snow is white') is for me *a priori* and empirically indefeasible.

'*True*$_{ss}$' and '*false*$_{ss}$' apply only to sentences I understand, and every instance of the schemas

'*S*' is true$_{ss}$ iff *S*
'*S*' is false$_{ss}$ iff not-*S*

is for me *a priori* and empirically indefeasible in a way that makes instances of

'*S*' is true$_{ss}$
'*S*' is false$_{ss}$

cognitively equivalent for me to their corresponding instances of

S
Not-*S*,

where to say that two sentences are "cognitively equivalent" for a person is to say that "the person's inferential procedures license a fairly direct [and 'more or less indefeasible'] inference from any sentence containing an occurrence of one to the corresponding sentence with an occurrence of the other substituted for it; with the stipulation … that the occurrence to be substituted for is not within the context of quotation marks or an intentional attitude construction" (Field, 1994a, p. 107, fn. 2).[4]

'*Refers*$_{ss}$' applies only to names I understand, and every instance of the schema

If *n* exists, then '*n*' refers to *n*

is for me *a priori* and empirically indefeasible. (Thus, my acceptance of the sentence '"Ned Block" refers$_{ss}$ to Ned Block' is entirely independent of whether or not anyone ever used 'Ned Block' to refer to Ned Block and of whether or not his parents gave him that name.)

'*True-of*$_{ss}$' applies only to predicates I understand, and every instance of the schema

'*F*' is true-of$_{ss}$ *o* iff *o* is *F*

is for me *a priori* and empirically indefeasible. Similarly for predicates of arity greater than one, although representing this in a schema would require special conventions for correlating instances of the right-hand side of

'R^n' is true-of$_{ss}$ $< o_1, \ldots, o_n >$ iff $R^n(o_1, \ldots, o_n)$

with sentences of my language, such as 'Jane gave her tiara to Oxfam.'

I trust it's clear that the foregoing stipulations have no implications at all as regards the truth-conditions of any sentence of my language, or as regards what any expression in my language means, refers to, or is true of, as 'means,' 'true,' 'refers,' and 'true of' are used by an English-speaking neutral observer of the inflationism–deflationism fray. Radical Deflationism gives every speaker of every language her own egocentric disquotational semantic notions. But knowing how, say, a speaker of Inuit uses her egocentric disquotational predicates would not enable you to infer anything about what her expressions mean, refer to, or have as their truth-conditions. This is especially brought home by the following observation. If one thinks of a language as an abstract object that may or may not be used by anyone – say, as a pairing of sounds and meanings over an infinite domain – then there are infinitely many distinct languages that share exactly the same expressions as English. For example, whereas in English

'Snow is white' means that snow is white
'Grass is green' means that grass is green
'Coal is black' means that coal is black

in another language, English*,

'Snow is white' means that coal is black
'Grass is green' means that snow is white
'Coal is black' means that butter is fattening.

If the expressions of a person's idiolect are the same as those of English and English*, then the question arises as to whether she speaks English, English*, or another one of the infinitely many languages whose expressions are shared with those two languages. Now suppose that my use of the expressions in my idiolect is such that any informed neutral observer would confidently claim that my language is English*. Notwithstanding that, it would remain the case that in my spoken language

'Snow is white' means$_{ss}$ that snow is white
'Grass is green' means$_{ss}$ that grass is green
'Coal is black' means$_{ss}$ that coal is black.[5]

A central claim of Radical Deflationism will be that we have no need of any inflationist semantic notions, and that the only semantic notions we need are ones definable in terms

of the core egocentric disquotational notions (semantic$_{ss}$ notions, in my case). But what need do we have for the radical deflationist's egocentric disquotational notions, notions that apply only to expressions one understands? I'm not aware that the radical deflationist has at hand an answer for every one of the disquotational notions he recognizes, especially for his notion of meaning$_{xx}$ that applies only to sentences one understands, but he does have an answer as regards his egocentric disquotational notion of truth (in my case, the notion of truth$_{ss}$). It's an answer perhaps first made explicit by Quine:

> [T]he truth predicate is superfluous when applied to a given sentence; you could just utter the sentence. But it is needed for sentences that are not given. Thus we may want to say that everything someone said on some occasion was true, or that all consequences of true theories are true. (Quine, 1992, p. 80)

Radical deflationists such as Stephen Leeds and Hartry Field understand Quine to be saying that the *only* reason we need a truth predicate is that it functions as a device for expressing certain infinite conjunctions and disjunctions,[6] and their point is that the purely disquotational egocentric notion of truth is sufficient to satisfy that need. For example, in my idiolect the sentences

(1) Ava said something true$_{ss}$
(2) Everything Bob said is true$_{ss}$

are equivalent, respectively, to

(3) Ava said 'Snow is white' and snow is white, or Ava said '68 + 57 = 5' and 68 + 57 = 5, or …
(4) If Bob said 'Snow is white,' then snow is white, and if Bob said 'Fleas have souls,' then fleas have souls, and …

This, however, needs qualification in at least three respects. First, as Field (1994a, p. 120, fn. 17) recognizes (and no doubt Leeds as well), (1) isn't equivalent to (3) and (2) isn't equivalent to (4): nothing in (3) or (4) entails that the sentences referred to in them are all the sentences of my idiolect, so it's logically possible for (3) to be false and (1) true by virtue of the fact that the only true$_{ss}$ sentences Ava uttered are not among the sentences referred to in (3), and it's logically possible for (4) to be true and (2) false by virtue of the fact that none of the false$_{ss}$ sentences Bob uttered are among the sentences referred to in (4). Second, when Quine wrote that the truth predicate "is needed for sentences that are not given" he had in mind not only one's need to say things like 'I managed to say something true in my lecture today,' where I am talking about my own sentences, but also such things as 'Not everything the Pope says when he's speaking *ex cathedra* is true,' when I don't understand a word of Latin. But of course, as so far described, the radical deflationist doesn't have the resources to say that. Third, it may be that while (1) and (2), *which use the stipulatively introduced predicate 'true$_{ss}$,'* are correct, they aren't useful characterizations of Ava or Bob. For it may be that, while (1) and (2), which use the predicate 'true$_{ss}$,' are correct,

(5) Ava said something true
(6) Everything Bob said is true,

which use the ordinary language predicate 'true,' are incorrect. For it may be that, while Ava's and Bob's sentences are the same as mine, they mean – now using 'mean' as its used in

ordinary language – quite different things for Ava and Bob than they do for me. The radical deflationist needs to introduce notions that will enable him to claim that his notions are able to confer the benefits that our ordinary semantic notions may legitimately claim to provide. This is our segue to the next stage, but a final point is in order before we get to it.

This is that Radical Deflationism's claim *that the only reason we need a notion of truth is as a device of disquotation* is hostage to the theory's ability to meet what we will presently see is its greatest challenge – namely, to show that it has the wherewithal to account for the role of content in propositional-attitude explanations. For suppose I explain Olga's petitioning to have her marriage annulled by revealing that she has recently come to believe *that when her husband married her he was already married to someone else*. Since a belief that *P* is a belief that is *true iff P*, I have apparently explained Olga's petitioning for an annulment in terms of her being in a state with a certain *truth-condition* – to wit, in terms of her being in a state that is true iff her husband was married to someone else when he married Olga. It's incumbent on the radical deflationist to show that he can account for the role of truth-conditions in propositional-attitude explanation using only a deflationist-licensed notion of truth, and this is an issue we have yet to consider.

Stage Two: Foreign Sentences

Our egocentric disquotational notions can't apply to foreign sentences we don't understand, but if the radical deflationist is to show we don't need inflationist semantic notions to get the benefits we actually get from the semantic notions we actually use, he will want to show how he can use his core egocentric disquotational semantic notions to define non-egocentric non-disquotational semantic notions to apply to foreign sentences we don't understand, and this because we will certainly want to be able to use the utterances and propositional-attitude-states of foreign language speakers as a source of information about the world and to predict and explain their behavior. How is that to be done?[7] However the radical deflationist tries to show it can be done, he must take care not to end up in effect defining the very inflationist "correspondence" semantic notions the avoidance of which is the very point of the position he is trying to develop. At the same time, as Field points out, if he does find himself realizing that he does need inflationist notions to accommodate foreign language utterances (or, for that matter, anything else), then that would have the unexpected benefit of proving to him that what he thought couldn't be done could be done. That is why Field's official position isn't Radical Deflationism but is rather what he calls *methodological deflationism*: the methodological policy that "we should start out assuming [Radical Deflationism] as a working hypothesis; we should adhere to it unless and until we find ourselves reconstructing what amounts to the inflationist's relation '*S* has the truth-conditions *p*'" (Field, 1994a, p. 119). Of course, Field wouldn't be justified in accepting methodological deflationism unless he thought there was a pretty good *prima facie* case to be made for thinking that the only semantic and propositional-attitude notions we need are those permitted by Radical Deflationism. The feasibility of methodological deflationism turns on whether there is a pretty good *prima facie* case to be made.

Field mentions two approaches the deflationist might take to accommodating foreign language utterances we don't understand. The first, which he says is the least satisfactory of the two approaches, is a weakening of Radical Deflationism that he calls "extended-disquotationalism." This would be "to use a notion of interlinguistic synonymy: where '*S*' is a foreign sentence I don't understand, regard '*S* is true' as equivalent to '*S* is synonymous

with a sentence of ours that is true in the pure disquotational sense'" (Field, 1994a, p. 128), where 'synonymy' is a relation defined in terms of certain of the conceptual-role and indication-relation features of my own words.[8] The challenge for the deflationist disposed to take this option, Field says, would be to define a notion of interlinguistic synonymy without relying on a prior notion of truth-conditions, and he is very skeptical that that can be done. I would have thought that an even bigger problem for extended-disquotationalism is that it's hard to see how defining a notion of interlinguistic synonymy wouldn't be tantamount to defining an inflationist notion of truth-conditions. For suppose the radical deflationist were to devise a notion of interlinguistic synonymy. Such a notion would doubtless be defined using conceptual-role and indication-relation features of my sentences; but whatever features of my words were used to define a notion of interlinguistic synonymy, they would have to be physicalistically acceptable, and for every two sentences *S* and *S′* of my language whose truth_{ss} conditions differed, there would have to be distinct properties φ and φ′ such that (i) *S* has *φ* and *S′* has *φ′* and (ii) a foreign sentence was for me synonymous with *S* iff it had *φ* and synonymous with *S′* iff it had *φ′*. Suppose such a definition of synonymy at hand. Then for every sentence *S* of my language, the predicate '___ means that *S*' will be interlinguistically applicable and will ascribe the same use-dependent property to every sentence of which the predicate is true. Wouldn't that be one kind of inflationist conception of meaning and, *a fortiori* (since a sentence's meaning that *S* entails its being true iff *S*), one kind of inflationist conception of truth-conditions? Field raises this question for a view he calls 'quasi-disquotationalism' apparently without noticing that extended-disquotationalism entails quasi-disquotationalism (Field, 1994a, p. 131).

The second option Field says is available to the radical deflationist is the one he thinks that theorist will need to adopt, so presumably it's an option he thinks might give the radical deflationist all that he can legitimately expect to gain from a way of assigning truth-conditions to foreign sentences he doesn't understand. The option is based on the notion of a foreign sentence's being "*true relative to a correlation* of it to one of our sentences" (Field, 1994a, p. 128), where:

> For any foreign language *L* and any correlation *C* of *L* sentences with my sentences, an *L* sentence *S* is *true relative to C* iff there is a sentence *S′* of mine such that *C* correlates *S* with *S′* and *S′* is true_{ss}.

The deflationist will then explain that:

> There is no such thing as a sentence I don't understand being *per se* true or false. Ways of correlating sentences of a foreign language with my sentences are in effect ways of translating that language into mine. There is no question of a translation being right or wrong, of being the *correct* or *incorrect* translation of a foreign sentence into my language, only of a translation's being better or worse in a way that is "highly context-dependent (since the purposes for which they are better or worse vary from one context to the next)" (Field, 1994a, p. 128). If I'm unable to interpret a foreign sentence, then "it makes no sense [for me] to inquire whether it is true (except perhaps in counterfactual terms about how I would interpret it under definite conditions)."[9]

This is pretty radical stuff. I don't understand a word of Arabic, but I would have thought that infinitely many Arabic sentences are true or are false irrespective of any way of

correlating them with my sentences, and therefore irrespective of how I choose to interpret them or whether or not it's even possible for me to interpret them; and I would have thought that if a speaker of English translated 'La neige est blanche' as anything other than 'Snow is white,' then he simply mistranslated it: the French sentence means in French what the English sentence means in English, and not to know that is not to know what at least one of the two sentences means. If, however, the only notion of truth I am able to apply to foreign sentences I don't understand is the one Radical Deflationism makes available to me, then I must accept that foreign sentences I don't understand have no truth-conditions, and therefore no truth-values – except relative to this, that, or the other way of correlating those sentences with mine. The departures from common sense snowball. For example, I have for a long time taken myself to have a considerable amount of general knowledge about speakers of, say, Japanese, even though when I hear Japanese speech I can't even tell where one word ends and another begins. I know that many Japanese have bought iPhones, that many have been tourists in the United States, that many have applied and gone to universities, that many get married, that many who get married later get divorced, that some join the army, that some quit their jobs, that some are orthopedic surgeons who specialize in knee replacements, and so on and on and on. But according to Radical Deflationism, it's impossible for me to know any of those things, and this because the theory entails that there can be no fact of the matter as to whether a speaker of Japanese bought an iPhone, quit her job, filed for divorce, performed a knee replacement, or did any of the myriad other things I thought I knew they did. There can be no fact of the matter about such things because to do any of them requires acting with intentions with particular contents and Radical Disquotationalism entails that there can be no fact of the matter about the contents of the propositional-attitude-states of speakers of languages we don't understand. For if we were able to assign objective contents to their propositional-attitude-states, then we would surely also be able to assign objective contents to the sentences they use to express those states.

Does the fact that Radical Deflationism entails these departures from common sense constitute an *objection* to it? Not if it can be shown that all the real benefits of having our commonsense conception of truth could just as easily be had if each person used only her own egocentric disquotational notions of truth and falsity together with whatever extended notions of truth and falsity it was permissible for her to define in terms of them.

Finally, we should note that the radical deflationist's line on foreign utterances can be used to deflect what is apt to seem to be another highly counter-intuitive departure from common sense. Recall that, for me, Radical Deflationism's apparent substitute for 'means,' 'means$_{ss}$,' applies to all and only expressions I understand, and that for example

'Snow is white' means$_{ss}$ that snow is white

is for me analytic, that is, *a priori* and empirically indefeasible. This entails that the displayed meaning$_{ss}$ statement would have been true even if I had used 'Snow is white' the way I actually use 'Coal is black,' and that is apt to seem a capricious departure from our commonsense notion of meaning according to which 'Snow is white' would have meant *that coal is black* if I had used 'Snow is white' the way I actually use 'Coal is black.' While it's true that 'Snow is white' would have meant$_{ss}$ *that snow is white* however I used that sentence, the radical deflationist does have a way of capturing what the ordinary language notion of meaning would say: he can say that in interpreting my utterances in counterfactual worlds where I use 'Snow is white' the way I actually use 'Coal is black,' I wouldn't, and shouldn't, interpret myself

using my egocentric homophonic disquotational notion of meaning$_{ss}$ but would instead interpret myself as though I were speaking a foreign language, in which case I would no doubt use 'Coal is black' to "translate" my counterfactual utterances of 'Snow is white.'

Stage Three: Utterance Understanding

Relative to the pretense that all the sentences of my language are unambiguous and non-indexical, we could view the predicates stipulated to express my egocentric notions of truth and falsity – *viz.* 'true$_{ss}$' and 'false$_{ss}$,' respectively – as applying to *sentences* I understand, and I could represent the radical deflationist as saying that for me to understand a *sentence* is just for it to be, or to be correlated with, a sentence of my mentalese and thereby to have a conceptual role for me. But 'true$_{ss}$' and 'false$_{ss}$' must also have application to *utterances* I understand of sentences I understand, so we need to see what the radical deflationist should say about understanding an *utterance* of a sentence versus understanding the *sentence* uttered. The question presses because it's not sufficient for understanding an utterance of a sentence *S* that one understand *S*. For a start, one can't understand an utterance unless one knows that it occurred. But even if one understands *S* and knows that an utterance of it occurred, that still isn't sufficient for understanding the utterance. For example, the sentence

(1) The force of an allegory's bite can exceed 3,000 pounds

is (we may suppose) an unambiguous eternal sentence I understand (and, of course, know to be false$_{ss}$). Now suppose I hear Fester utter (1). It's very *un*likely that I will interpret his utterance of (1) as a statement that the force of an allegory's bite can exceed 3,000 pounds. If I were wearing my inflationist hat, then how I would interpret Fester's utterance would depend on what I thought his beliefs and intentions were in uttering (1), and no doubt I would conclude that, like Mrs Malaprop, he confuses 'allegory' and 'alligator' and that what he meant in uttering (1) was that the force of an alligator's bite can exceed 3,000 pounds. But whatever interpretation I came up with, I would take that interpretation to be either objectively correct or objectively incorrect,[10] as determined by the intentions and beliefs Fester had in uttering (1). Now that I am trying on the radical deflationist's hat, however, I must recognize that how I interpret Fester's utterance isn't determined by what I think his beliefs and intentions were in uttering (1), for I will recognize that, just as there is no objective fact of the matter as to what his utterance means, so, too, there will be no objective fact of the matter as to what he believes and intends in uttering (1). How I interpret Fester's utterance is simply a matter of which sentence of mine I use to process the utterance, and *that* will be determined by which mapping of his utterance onto a sentence of mine will best satisfy my interests in interpreting him. If, for example, I process the utterance using my sentence

(2) The force of an alligator's bite can exceed 3,000 pounds,

then I am interpreting his utterance as a statement about the force of an alligator's bite. In other words, my saying that Fester's utterance is true$_{ss}$ doesn't mean that it's true on the objectively correct interpretation of it ("the idea of a 'correct understanding' of a sentence or utterance is a semantic notion that has no place when we are discussing purely disquotational truth"; Field, 1986, p. 134); it means that it's *true-as-I-understand-it*, and I'm free to understand it any way I regard as appropriate in the circumstances. Evidently, then, the radical deflationist must say that the sense in which I must understand an utterance – even an utterance of a sentence of my own idiolect – in order for my predicates 'true$_{ss}$' and 'false$_{ss}$' to

have application to it is simply that I process it with a sentence I understand, that is, a sentence that has a conceptual role in my mentalese. Consequently, since I have decided to process Fester's utterance with my sentence (2), then that sentence represents my understanding of the utterance, and when I claim that the utterance is $true_{ss}$ I'm claiming that it's true-as-I-understand-it, which makes that claim cognitively equivalent for me to Fester's utterance of (1), which in turn makes it cognitively equivalent for me to (2). Ways of interpreting utterances even of sentences I understand are in effect ways of translating those utterances into sentences of mine. There is no question of a translation being right or wrong, of being the *correct* or *incorrect* translation of an utterance into my language, only of a translation's being better or worse in a way that is "highly context-dependent (since the purposes for which they are better or worse vary from one context to the next)" (Field, 1994a, p. 128). If I'm unable to interpret an utterance, then "it makes no sense [for me] to inquire whether it is true (except perhaps in counterfactual terms about how I would interpret it under definite conditions)" (Field, 1986, p. 62). The radical deflationist's treatment of utterances of sentences we understand is essentially the same as his treatment of foreign language sentences we don't understand.

Stage Four: Belief

What can Radical Deflationism say about our talk of beliefs being true or false? It would, I believe, be something along the following lines (see Field, 2001b). We start with a stipulative definition:

x believes S* iff *S* is a sentence of *x*'s mentalese that is tokened in *x*'s belief box.[11]

If we were radical inflationists we would then want some refinement of the view that:

- *x* has a belief iff for some proposition *p*, *x* believes *p*
- *x* believes *p* iff, for some *S*, *x* believes* *S* and *S* means *p* in *x*'s mentalese,
  where 'means' expresses a certain use-dependent relation between sentences and propositions, and thus a relation that demands an explication in non-intentional terms.

There are a couple of reasons why the radical deflationist can't say that. One is that it requires a use-dependent notion of meaning and truth-conditions (if *S* means *p* then *S* is true iff *p* is true), what Field calls *correspondence truth-conditions*. The other is that the inflationist account of belief presupposes that there can be a fact of the matter about what someone believes, the content of her belief, even if we are unfamiliar with her and unable to understand the sentences she believes*; but the radical deflationist's unrelativized meaning and truth predicates can be applied only to sentences or utterances one understands.

Now, the only unrelativized radical deflationist truth predicates I have are '$true_{ss}$' and '$false_{ss}$.' What can I say about the truth-conditions of (1)?

(1) Ralph believes that *S*.

Well, if Ralph believes* '*S*' and '*S*' is a sentence I understand, then if I'm going by what '*S*' $means_{ss}$, I can accept (1). But suppose that the sentence Ralph believes* is 'Exercise is enervating' and that he uses that sentence the way I use 'Exercise is energizing.' In that case I should no doubt decide my interests are best served by "translating" 'Exercise is enervating' in Ralph's mentalese as my sentence 'Exercise is energizing.' This is just to repeat what in

effect we already knew – that the radical deflationist should recommend that, if '*S*' is a sentence I understand and I know both that Ralph believes* '*S*' and that Ralph uses '*S*' the same way I do, then I should believe* 'Ralph believes that *S*,' but if I decide '*S*' in Ralph's language is best "translated" as my sentence '*S′*,' then I should believe* 'Ralph believes that *S′*.' In any case, I must recognize that there can be no fact of the matter as to what Ralph believes that would make a belief report about him objectively correct or objectively incorrect, but should recognize that there is nothing to constrain what I take him to believe other than my pragmatic concerns in ascribing beliefs to him. This of course generalizes, *mutatis mutandis*, to every kind of propositional-attitude report.

Again, this is pretty radical stuff, even more radical than the radical deflationist's line on foreign language sentences I don't understand. If I know that Tamiko believes* the Japanese sentence *S* but I don't understand *S*, then, given Radical Deflationism, I must say that there is no fact of the matter as to the truth-conditional content of the belief state Tamiko's believing* *S* realizes. The most I can say is that she has a belief that is true relative to certain ways, and false relative to other ways, of correlating *S* with a sentence of mine. The same is even true of a person who thinks in English when she believes* a sentence and I'm undecided about which sentence of mine I should use to understand that sentence. Since I can be said to understand only an extremely minute fraction of the sentences believed*, desired*, or intended* by all the people there are, were, or will be, we see that Radical Deflationism's line on truth talk about propositional attitudes entails a pretty radical solipsism. For not only must I conclude that there can be no fact of the matter as to whether any native speaker of Japanese ever got married, bought a Honda, or applied to graduate school, I must now conclude that for nearly every person who has ever lived there is no fact of the matter as to whether any of them ever bought anything, accepted a job, or told a lie, or did anything else the doing of which requires acting with particular intentions.

Stage Five: Indexicality and Ambiguity

Up to now I have been pretending that my language is unambiguous and non-indexical. Given that pretense I could say that the egocentric disquotational semantic notions Radical Deflationism licenses for me could be introduced with the stipulations that:

'Means$_{ss}$' applies only to expressions I understand, and every instance of the schema
  '*S*' means$_{ss}$ that *S*
is for me *a priori* and empirically indefeasible.

'True$_{ss}$' and 'false$_{ss}$' apply only to sentences I understand, and every instance of the schemas
  '*S*' is true$_{ss}$ iff *S*
  '*S*' is false$_{ss}$ iff not-*S*
is for me *a priori* and empirically indefeasible, and therefore instances of
  '*S*' is true$_{ss}$
  '*S*' is false$_{ss}$
are cognitively equivalent for me to their corresponding instances of
  S
  Not-*S*.

'*Refers*$_{ss}$' applies only to names I understand, and every instance of the schema
  If *n* exists, then '*n*' refers to *n*

is for me *a priori* and empirically indefeasible.

'True-of$_{ss}$' applies only to predicates I understand, and every instance of the schema
'*F*' is true-of$_{ss}$ *o* iff *o* is *F*
is for me *a priori* and empirically indefeasible.

But what will Radical Deflationism stipulate for my semantic$_{ss}$ expressions when it recognizes that my language is ambiguous and indexical, and therefore, presumably, has to provide completions for forms such as the following?

(1) 'Visiting relatives can be boring' means$_{ss}$ …
(2) 'She is ready' means$_{ss}$ …
(3) 'She' means$_{ss}$ …
(4) A token of 'she' refers$_{ss}$ to *x* iff …
(5) A token of 'She is a novelist' is true$_{ss}$ iff …
(6) 'Tall' means$_{ss}$ …
(7) A token of 'tall' is true-of$_{ss}$ a thing iff …

It's not clear to me that the radical deflationist is able to provide completions of any of these forms that she would find acceptable. Consider (3), (4), and (5). Suppose the pronoun 'she' has only its referential use in my language. Then one sort of inflationist would say (at least to a first approximation):

The meaning of 'she' is that function *f* such that, for any token τ of 'she' and any *x*, $f(\tau) = x$ iff *x* is the female to whom the speaker referred with τ; nothing otherwise.

For any *x* and token τ of 'she,' *x* is the referent of τ iff $f(\tau) = x$; otherwise τ has no referent.

A token τ of 'She is a novelist' is
true iff for some *x*, *x* is the referent of the token of 'she' contained in τ and *x* is a novelist;
false iff for some *x*, *x* is the referent of the token of 'she' contained in τ and *x* is not a novelist;
neither true nor false iff nothing is the referent of the token of 'she' contained in τ.

What might the radical deflationist say?

Field discusses indexicality. He opens that discussion by saying he wants his notion of pure disquotational truth to apply to tokens of indexical sentences but that "one substantial worry about [Radical Deflationism] is whether it can accommodate this."[12] He doesn't say why this is a substantial worry, but he does say why he thinks it shouldn't be any worry at all. Let '$S(i_1, \ldots, i_n)$' be schematic for any sentence of mine with *n* occurrences of indexicals or demonstratives. Field first defines a relativized truth predicate for the sentence-*type* '$S(i_1, \ldots, i_n)$':

'$S(i_1, \ldots, i_n)$' is *true relative to a sequence of objects* $< a_1, \ldots, a_n >$ iff $S(a_1, \ldots, a_n)$.

For example, 'She never loved him' is true relative to < Jill, Jack > iff Jill never loved Jack. That defined notion of truth-relative-to-a-sequence is then in effect used to define the application of 'true$_{ss}$' to tokens of '$S(i_1, \ldots, i_n)$':

(A) A token of '$S(i_1,\ldots, i_n)$' is true$_{ss}$ iff there are objects $a_1, \ldots, a_n$ that I "associate" with the uttered tokens of 'i_1,' …, 'i_n,' respectively, and '$S(i_1,\ldots, i_n)$' is true relative to $< a_1, \ldots, a_n >$.[13]

Field goes on (nearly enough) to explain "association" in a way that implies that I associate objects $a_1, \ldots, a_n$ with the indexicals 'i_1,' …, 'i_n' just in case I processes the utterance of '$S(i_1,\ldots, i_n)$' with a sentence '$S'(\alpha_1, \ldots, \alpha_n)$' of my mentalese such that (i) '$S'(\alpha_1, \ldots, \alpha_n)$' is true$_{ss}$ iff $S'(\alpha_1, \ldots, \alpha_n)$ and (b) $\alpha_1 = a_1, \ldots, \alpha_n = a_n$.[14]

It may be that Field didn't really intend (A) as a proper definition, but merely as an account of how I interpret utterances of indexical sentences when I'm actually party to them, for as a definition, (A) is problematic. Read as a definition, there is prefixed to the definition an implicit necessity operator: 'Necessarily, a token of "$S(i_1,\ldots, i_n)$" is true$_{ss}$ iff ….' But so read, (A) entails that the only tokens of '$S(i_1,\ldots, i_n)$' that can have truth$_{ss}$-values are those that I interpret, and that would mean that if when I'm not around you say 'She was a novelist' intending to communicate that George Eliot was a novelist, then your uttered token of 'she' doesn't refer$_{ss}$ to anyone and your utterance has no truth$_{ss}$-value. But when Field said he wanted his notion of pure disquotational truth – which in my case is 'true$_{ss}$' – to apply to indexical utterances he clearly intended to include utterances in my absence of indexical sentences by those who speak my language. Would Field want to revise (A) to (A′)?

(A′) A token of '$S(i_1,\ldots, i_n)$' is true$_{ss}$ iff there are objects $a_1, \ldots, a_n$ that if I were party to the utterance of that token I would associate with the uttered tokens of 'i_1,' …, 'i_n,' respectively, and '$S(i_1,\ldots, i_n)$' is true relative to $< a_1, \ldots, a_n >$.

I doubt he would want to make that revision. For one thing, counterfactuals like

> If I had been party to α's utterance of 'She's a novelist' I would have associated β with the uttered token of 'she'

rarely have determinate truth-values, and, for another thing, if at the moment of your utterance I were to have a cerebral infarction which causes me to associate your utterance of 'she' with Rosa Luxembourg, would Field really want to say that your utterance is true$_{ss}$ just in case Rosa Luxembourg was a novelist?

I'll skip what the radical deflationist (i.e., Field) has to say about ambiguity, since it runs pretty much along the lines of what he says about indexicality.

Stage Six: Radical Deflationist Truth in Explanation – Where Push Comes to Shove

Radical Deflationism's claim, we already noticed, isn't that the disquotational semantic notions it provides are the notions expressed by ordinary language semantic terms. Its claim is that the semantic notions it provides can do all the explanatory work that semantic notions can legitimately be expected to do. This is where push comes to shove, for the plausibility of Radical Deflationism rides entirely on the plausibility of that claim.

We need to be clear about what the issues really are. No one disputes that semantic notions play an important role in enabling us to acquire knowledge about the world from what people write and say, and in explaining and predicting their behavior. What we want to know is what those roles are and what enables semantic notions to play them. There is also a question about *which* semantic notions we are talking about, and here we find an

assumption that is sometimes made, but is wrong. To see the mistake I have in mind, suppose Jane offers the following two explanations:

(A) I know that Clyde's middle name is 'Ignatz' because he told me it was; he wouldn't have told me that unless he believed he knew it; and his believing that he knows it is extremely good evidence that his belief is *true*.

(B) Of all the many doctors Frank consulted, Dr Jones was the only one who succeeded in relieving his symptoms, and that was because she was the only doctor whose belief about the cause of those symptoms was *true*.

Now suppose a radical deflationist were to argue that (i) egocentric disquotational truth can play the role truth plays in (A) and in (B), for (ii) the explanation (A) offers remains the same if we replace the sentence

his believing that he knows it is extremely good evidence that his belief is true

with the sentence

his believing that he knows that his middle name is 'Ignatz' is extremely good evidence that his middle name is 'Ignatz';

and the explanation (B) offers remains the same if, using substitutional quantification, we replace the phrase

whose belief about the cause of those symptoms was true

with the phrase

whose belief about the cause of those symptoms was such that ΠS(('S' purports to identify the cause of Frank's symptoms & Dr Jones believes that S) → S).

The problem with this argument is that (ii) doesn't entail (i). The reason it doesn't is that *it doesn't address the truth-conditions entailed by the that-clauses in the explanations' belief ascriptions*. The heavy lifting in propositional-attitude explanations is done by the *contents* ascribed to the beliefs (and other propositional attitudes) cited in those explanations, and, as we have already observed, those contents are truth-condition entailing: the claim that Clyde believes *that his middle name is 'Ignatz'* entails that Clyde has a belief that is *true if and only if his middle name is 'Ignatz'*. The difficult task for the radical deflationist isn't to explain overt uses of 'true' like those in (A) and (B); it's to explain the use of *propositional content* in those and other propositional-attitude explanations.

The notions expressed by our ordinary language propositional-attitude expressions – 'believes that such and such,' 'desires such and such,' 'intends to do such and such' – do a lot of extremely important explanatory work for us. The plausibility of Radical Deflationism turns on its ability to do the same work. Before we address that question directly we should first say something about some of the key features of our propositional-attitude expressions as we actually use them. Here is a brief annotated inventory of what some of those features appear to be.

a) Propositional-attitude predicates such as 'believes that Brutus killed Caesar' and 'intends to buy a villa in Cap Ferrat' apply interpersonally and univocally, even among monolingual speakers of different languages. We depend on this as when we say things like 'The vast majority of citizens of other countries believe that the United States had no legitimate reason for invading Iraq.' The same is true of predicates that entail propositional-attitude properties, such as 'bought a villa in Cap Ferrat,' which apply to a person only if she acted with certain intentions.

b) Do propositional-attitude properties play a causal-explanatory role in propositional-attitude explanations, as, for example, when one explains that Ava passed the salt to you because she believed that you asked her to? Define 'causal-explanatory.' If Henry took pain medication because he was having a migraine, is the property of having a migraine playing a "causal-explanatory role" in that explanation? If you say yes, I have no trouble with that: I assume you say it because Henry's migraine was a cause of his taking the pain medication and that the cause's having the property of being a migraine is a causally relevant property of it, in that, all else being equal, the cause wouldn't have been a cause had it not had that property. But if you say that being a migraine plays a "causal-explanatory" role in the explanation of Henry's taking pain medication, then parity of reasoning should require you to say that the property of being a belief *that you asked her to pass the salt* is playing a causal-explanatory role in the explanation of Ava's passing you the salt. It's less clear what you would mean if you said that the property of having a migraine isn't playing a causal-explanatory role in the Henry explanation. I might guess that you accepted something like Jaegwon Kim's "principle of explanatory exclusion," that two events can't have two separate and complete explanations (see, e.g., Kim, 1988) and that you thought the migraine explanation couldn't be identified with a more basic non-psychological explanation. In that case I would want to have a conversation with you about explanatory exclusion. The important question, of course, is what radical deflationists mean by 'causal-explanatory role.' I'm not aware of any place where Field tries to say what it is. Stephen Leeds implies that a notion plays a causal-explanatory role if it's needed in a causal law (Leeds, 1978, p. 116), but I should think that if there are laws of our commonsense propositional-attitude psychology, then they are content-involving laws such as 'For any person x and state of affairs s, if x desires s to obtain and, for some act *A*, believes *that s will obtain only if x does A*, and if such-and-such other conditions are satisfied, then, ceteris paribus, x does *A*.'[15] The notion of a causal-explanatory role (whatever exactly that notion is) is important in the present discussion because the radical deflationist claims both that we need inflationist semantic notions only if we need semantic notions that are explicable in physical terms, and that they need to be so explicated if, but only if, they are needed to play a causal-explanatory role.

c) It's pretty clear that the properties expressed by the propositional-attitude predicates we actually use are use-dependent contingent properties. But are they physicalistically explicable? Define 'physicalistically explicable.' Field, who makes heavy use of the expression, couldn't define it when he wrote his Tarski paper. There he is deliberately vague as to what it would be for a notion to be explicable in physical terms. He says it's "very hard to take seriously" the popular idea that explicability in terms of physical facts requires that "for every acceptable predicate '$P(x)$' there is a formula '$B(x)$' containing only terminology from physics, such that '$\forall x(P(x) \Leftrightarrow B(x))$' is true" (Field, 1972, p. 11, fn. 9), but he admits not to having a precise characterization of his own and pretty much concludes that the notion is whatever scientific practice needs it to be. But in a paper published 20 years after his Tarski paper, he suggests that "if we are to accept a special-science explanation of something, we are

committed to the possibility in principle of finding a physical explanation of that thing *in which the structure of the special-science explanation of it is preserved*" (Field, 1992, p. 278; emphasis is Field's). This strikes me as implausible: 'Jack and Jill adopted a child because they wanted very much to have a child but learned that it was impossible for them to conceive one' might sketch a correct propositional-attitude explanation of the fact that Jack and Jill adopted a child, but what on earth would a physical explanation of that fact look like? I do think that if a propositional-attitude explanation E is correct it must in principle be possible to explain why E is correct in terms of underlying physical facts and their relation to the propositional-attitude facts E entails, where such an explanation would consist primarily in explaining why the propositional-attitude causes postulated by E are causes, and why the propositional-attitude properties of those causes are essential to their being causes. Such an explanation would no doubt necessitate myriad physical explanations of myriad and sundry physical facts, but I very much doubt that any one of those explanations would preserve E's structure. I don't take the fact that correct propositional-attitude explanations aren't shadowed by structurally identical physical explanations to show that propositional-attitude properties aren't reducible to physical properties in the sense that, for every propositional-attitude property Φ there is a logically complex property Π built up from physical properties such that having Π is metaphysically necessary and sufficient for having (some suitable precisification of) Φ. Field has said that one reason he came to doubt the correspondence theory of his Tarski paper was that it "proved extraordinarily difficult to develop the details of an adequate correspondence theory" (Field, 1986, p. 67). This is misleading. What has proved difficult is getting a correspondence theory using only the tools available to a philosopher without having to leave his armchair. Why should we expect properties that are metaphysically equivalent to our propositional-attitude properties to be discoverable by the slow-moving and storage-limited information-processing of our brains?

So much for ground clearing. It is important to keep in mind that the question

> Are semantic notions needed to play a causal-explanatory role in psychological or linguistic explanations?

isn't the same as the question

> Can the semantic notions provided by Radical Disquotationalism do the explanatory work that is done by the semantic notions we actually use?

For all we yet know, the answer to both questions is no; for whether or not the propositional-attitude and other semantic properties expressed by our propositional-attitude and semantic expressions *as we actually use them* are "causal-explanatory" or "physicalistically explicable" properties, they are inflationist properties in that they have application to all people, regardless of the languages they speak, and are use-dependent contingent properties. It's therefore crucial for the radical deflationist to show that in some relevant sense the explanatory benefits we get from the propositional-attitude notions we actually use can be had by using the notions he would substitute for them. Here is one reason that may not be such an easy thing to show. Common sense supposes that there are billions of intentional actions performed every day, nearly all of them by people with whom I'm unacquainted, speaking languages I don't understand, and that nearly all of these actions enjoy correct propositional-attitude explanations. For example, common sense has no trouble allowing

that the following explanation might be true, and even that I might know it, notwithstanding that Olga is a monolingual speaker of Russian and I don't understand a word of that language other than 'da' and 'nyet':

(E) Olga has petitioned to have her marriage annulled because she learned that her husband was married to someone else when he married Olga.

Explanations like (E) are extremely useful to us in myriad ways, but according to Radical Deflationism, I can't allow that (E) is correct. In fact, if I accept Radical Deflationism, I must conclude that the vast majority of propositional-attitude explanations thought to be correct are attempts to explain facts that don't exist in terms of other facts that don't exist. For I must suppose that the only people for whom there may be a fact of the matter as to the truth-conditional contents of their propositional attitudes are myself and the small number of people whose utterances I can understand – and then 'truth' in 'truth-conditional content' must be 'truth$_{ss}$' and 'fact' in 'fact of the matter' must be 'fact$_{ss}$,' the very thin notion of fact that goes with truth$_{ss}$. As for the billions of other propositional attitudes, I must recognize that they can have truth-conditional content only relative to their being correlated in this, that, or the other one of infinitely many ways with my sentences, where no one of those ways is the correct way of correlating them with my sentences. That is why I would have to conclude that the vast majority of propositional-attitude explanations thought to be correct are attempting to explain what they are attempting to explain by citing non-existent facts; at the same time, in most cases the facts they are attempting to explain would also be non-existent, because they would be facts, such as the fact that Olga petitioned to have her marriage annulled, about intentional actions that can be performed only by someone with beliefs and intentions with certain contents.

It might be thought that, while Radical Deflationism precludes me from accepting (E), there is something pretty close to (E) that I can accept, and which will serve me pretty much as well as (E) does. Wearing my commonsense hat, I have no trouble believing that Olga came to believe that her husband was already married to someone else when he married Olga, that her coming to believe that led to her intending to petition to have her marriage annulled, and that that led to her so petitioning. Wearing my radical deflationist hat, I can't, for example, say that Olga believes that her husband was already married to someone else when he married Olga, because according to Radical Deflationism my sentence

Olga believes that her husband was married to someone else when he married Olga

is equivalent to

Olga believes* a sentence of her Russian idiolect that is true$_{ss}$ – that is, true *as I understand it* – iff Olga's husband was married to someone other than Olga when he married Olga.

But for a sentence of Olga's Russian idiolect to be true as I understand it I must understand it, and in this case that would require me to have decided to interpret her sentence as equivalent to a certain sentence of mine. Of course, I do know that there is a standard way of translating Russian into English – no doubt a way of translating constructed by highly educated and linguistically sophisticated people who are completely bilingual in English and Russian – and I might have it on good authority that that method of translation would

correlate the sentence Olga believes* with my sentence 'Olga's husband was married to someone other than Olga when he married Olga,' and that, consequently, while I can't accept (E), I can accept something along the lines of

(E*) (E) is true relative to the standard way of translating Russian into English,

and if I'm determined to interpret Olga's sentences as equivalent to the English sentences with which they are correlated by the standard way of translating Russian into English, then I shouldn't be worse off than if I could accept (E) directly. There are, however, two problems with this response. The first is that it's question-begging for the radical deflationist to assume he can rely on the standard ways of translating foreign languages into English, because if those translation schemes were constructed on the basis of an inflationist notion of sameness of meaning, then the radical deflationist would find that the benefits of using his theory-approved notions were due to their unwitting reliance on an inflationist conception of semantic notions. For the radical deflationist, a translation scheme can be selected for interpreting foreign sentences only if it's selected on the basis of radical-deflationist-approved properties of sentences, such as conceptual-role and indication-relation properties, which are as available to the radical deflationist as they are to the inflationist. An inflationist who accepts the hypothesis that we think in a language-like system of mental representation will say that

x believes *p* iff, for some sentence *S* of *x*'s mentalese, *x* believes* *S* and *S* means *p* in *x*'s mentalese,

and she will assume that which proposition a mentalese sentence means is determined by some yet unknown package of properties of *S* that will include conceptual-role and causal-relation properties that may explain, *inter alia*, why *x*'s believing *p* is to some degree evidence that *p* is true. For the inflationist, the explanatory role that *x*'s believing *p* is able to play rides piggy-back on the explanatory role played at another level of explanation by the meaning-determining package of properties of the sentence *S* such that *x*'s believing* *S* realizes *x*'s believing *p*. The radical deflationist can agree with the inflationist that it's a conceptual-role/causal-relation package of the sentence *x* believes* that is really carrying the explanatory load without agreeing with her that that package is able to define that relation which a sentence in a person's mentalese must bear to a proposition in order for it to mean that proposition in that person's mentalese. Consequently, when he needs to interpret the sentences Olga believes*, desires*, or intends* he will look for a correlation scheme that enables him to exploit the explanatorily relevant properties of those sentences.

That correlation scheme may not be so easy to find. For one thing, how will the radical deflationist know *which* conceptual-role and causal-relation properties are the ones doing the underlying explanatory work? In fact, he can't know. In order merely to know what the explanatorily relevant conceptual-role properties are would require a complete computational psychology, and we are years from having that. As for picking out the causal properties one would need to explain why certain of a person's beliefs reliably indicate their truth, just consider how much neurophysiology one would have to master even to begin making a dent in that task, not to mention that much of what one would need to know about the neurophysiological workings of the brain and central nervous system is nowhere near being known. An enormous advantage of our ability to give commonsense propositional-attitude explanations and predictions is that we can give them without knowing anything about the

underlying properties that make those explanations and predictions possible, just as a person who knows nothing about how his computer works, or even the programs it's running, can explain and predict its behavior. Nor can the radical deflationist say with any degree of aplomb that he will select a system of correlation that correlates a sentence *S* of Olga's with a sentence *S′* of his only if *S* and *S′* share more or less the same relevant conceptual-role and causal-relation properties, for how will he know which properties are relevant and how will he know that the conceptual-role and causal-relation properties that play a certain role in the explanation and prediction of Olga's behavior play the same sort of role in the explanation and prediction of his relevantly similar behavior?

So far I've been wondering what sort of an explanation, if any, of Olga's petitioning for an annulment Radical Deflationism makes available to me if I don't understand the sentences Olga believes*, desires*, or intends*. But the most serious problem for the theory concerns how I might explain Olga's behavior when I *do* understand those sentences. To see what I mean, let's return to

(E) Olga has petitioned to have her marriage annulled because she learned that her husband was married to someone else when he married Olga

and let's suppose that I can understand Olga's sentences so that I have no trouble accepting as true_{ss} such sentences as 'Olga believed that her husband was married to someone else when he married Olga,' 'Olga intended to petition for an annulment,' and 'Olga has petitioned for an annulment.' Then it will be the radical deflationist's claim that he can accept (E) *when it's read in the way his theory requires him to read it*, thereby demonstrating that the only semantic notions we need in order to give such explanations as (E) are the ones his theory makes available. That claim, however, is false: the radical deflationist cannot accept (E) when the content-involving notions in it are taken to be his theory-approved notions. For (E) implies (a) that Olga's coming to believe that her husband was married to someone else when he married Olga was a cause of Olga's petitioning for an annulment and (b) that Olga's coming to have that belief was a cause of her petitioning for an annulment *because* it was a belief *that her husband was married to someone else when he married Olga*, where this implies that, all else being equal, she would not have petitioned for an annulment if her belief hadn't had that content. It ought to be clear that (b) is every bit as important as (a): without (b) we should have no explanation of why Olga's coming to have a certain belief was a cause of her petitioning for an annulment, and (b) helps to explain how someone who knew *that Olga learned that her husband was married to someone else when he married Olga* might have predicted that she was likely to seek an annulment. When, however, we read (E) in the way the radical deflationist requires it to be read, we see that, while he can accept (a) he can't accept (b). For suppose the radical deflationist in question is myself. Then I can't accept (b) because I must say that

Olga believes that her husband was married to someone else when he married Olga

is equivalent to

Olga believes* a sentence that is true_{ss} – that is, true as *I* understand it – iff 'Olga's husband was married to someone else when he married Olga' is true_{ss},

but it's plainly false that she wouldn't have petitioned for an annulment if the explainer hadn't interpreted a sentence of Olga's in a certain way.

Field is sensitive to this problem, but nowhere does he explicitly offer his official response to it. He acknowledges that "the most serious worry about [Radical Deflationism] is that it can't make sense of the explanatory role of truth conditions … in explaining behavior," but goes on to say that "unfortunately it is a big job even to state the worry clearly, and a bigger job to answer it; I must save this for another occasion" (Field, 1994a, p. 127). Apart from some remarks in the postscripts to "Mental representation" and "Deflationist views of meaning and content" in *Truth and the Absence of Fact* (Field, 2001a), the job is still being saved. But in the postscript to "Mental representation" he does suggest a response he may wish to develop. There he suggests that for the radical deflationist propositional-attitude explanation might be what he calls "projective" explanation. This alludes to the simulation theory of psychological explanation first proposed by Robert Gordon and further developed by Gordon, Alvin Goldman, and others (see, e.g., Gordon, 1986, and Goldman, 1989). In a projective explanation I explain another's behavior not by subsuming it under the generalizations of a folk theory that applies equally to all folk, but by imaginatively putting myself in the other's shoes and asking what I would do if I were in them. Field's gloss on this is that:

> [A "projective" explanation of someone's behavior involves] reference to the explainer's language even though that is not causally relevant to the behavior. When explaining a person's behavior (say the raising of his gun) in terms of his belief that there is a rabbit nearby, what I am in effect doing is explaining the behavior in terms of his believing* a representation that plays a role in his psychology rather similar to the role that 'There are rabbits nearby' plays in mine.… Such an explanation is still basically non-intentional: truth conditions play no real explanatory role. Of course, there is a sense in which my *sentence* 'There are rabbits' plays an explanatory role here: obviously not as a causal factor in the explanation, but as a device we use in picking out the agent's internal representation (which is a causal factor). (Field, 1978, p. 78)

As regards (E), what this projectivist line suggests is that the radical deflationist should reject (E), which does give an explanatory role to truth-conditions (whether or not that role is a causal-explanatory role), and, imagining Field to be the explainer, replace it with:

(E′) Olga has petitioned to have her marriage annulled and a cause of that petitioning is that Olga believed* a sentence that plays a role in her psychology that is similar to the role 'Olga's husband was married to someone else when he married Olga' plays in Hartry Field's psychology.

I know Hartry Field pretty well, but I'm very reluctant to say I know the role that the sentence about Olga's husband plays in his psychology. But there is a bigger problem. A monolingual speaker of Hindi could accept the explanation expressed by (E′) without having any idea of how to translate Field's sentence about Olga's husband into *her* language. As Field happily acknowledges, the meaning or truth-conditions of 'Olga's husband was married to someone else when he married Olga' plays no role in the explanation (E′) communicates. (E′) gives no more of an explanation of Olga's petitioning for an annulment than does:

> Olga has petitioned to have her marriage annulled and a cause of that petitioning is that Olga believed* a sentence that plays a role in her psychology that is similar to the role a certain sentence plays in Hartry Field's psychology.

The use of 'true' as a device for expressing certain infinite conjunctions and disjunctions is a red herring. The most important case for inflationist semantic notions is that such notions go hand in hand with inflationist propositional-attitude notions, and the most important case for them is that they seem to be needed to account for the role those notions play in commonsense propositional-attitude explanations of behavior, such as the fact that Olga petitioned for an annulment *because she believed that her husband was married to someone else when he married Olga*. It's this role that Radical Deflationism seems unable to accommodate.

II

The classical notion of a *proposition* in analytical philosophy is the one first clearly articulated by Frege – namely, that a proposition is an abstract, mind- and language-independent entity that has truth-conditions, and has its truth-conditions both essentially and absolutely (i.e., without relativization to anything).[16] To say that every proposition has truth-conditions is not to say that every instance of the schema

The proposition that *S* is true iff *S*

is true. Frege himself would say that the proposition *that the present King of France is bald*, as well as the sentence 'The present King of France is bald' which expresses it, is neither true nor false owing to the fact that there is no such person as the present King of France. Consequently, he would say that

The proposition *that the present King of France is bald* is true iff the present King of France is bald

is not true, because its left-hand side is false but its right-hand side is neither true nor false. The classical conception of a proposition does however entail that, whatever form a proposition's truth-conditions take, it will be a necessary, and therefore use-independent, fact that it has those truth-conditions. If, *pace* Frege, every instance of the schema

The proposition that *S* is true iff *S*

which expresses a proposition is true, then those instances are necessary, and therefore use-independent, truths. It's also arguable – and has been argued at length by Paul Horwich (1998) – that anyone who possesses the concepts required to understand a true instance of the schema would *ipso facto* implicitly know that it's true.

The preceding paragraph does *not* express a *deflationist* conception of propositional truth; it is what inflationists who use the classical notion of a proposition must say, and there is no "inflationist correlate" that the view seeks to deflate. Hartry Field formulates his deflationist theory without reference to propositions, but he acknowledges that there is a version of his theory that does refer to them (Field, 2015). That version would say that each of

(1) (Π*S*)('*S*' means the proposition that *S*)
(2) (Π*S*)(the proposition that *S* is true iff *S*)
(3) A sentence is true iff the proposition it means is true

is a use-independent conceptual truth, and from that it would follow that

(4) (Π*S*)('*S*' is true iff *S*)

is also a use-independent conceptual truth. Had Field stated his theory this way, his theory would be deflationist by virtue of holding that (1) was a use-independent conceptual truth. No theory is deflationist just by virtue of holding that (2) and (3) are use-independent conceptual truths.[17] The theories of propositional truth of Frege, Frank Ramsey, and Paul Horwich (Frege, 1918; Ramsey, 1927; Horwich, 1998) – as well as the prosentential theory of Dorothy Grover, Joseph Camp, and Nuel Belnap (Grover, Camp, and Belnap, 1975), which is a theory of 'true' as applied both to propositions and to sentences – all hold that (2) and (3) are use-independent conceptual truths, but they also hold that, since use determines meaning, (1), and with it (4), is a use-dependent contingent truth. Yet the literature labels these theories 'deflationist.' I have explained why no theory should be called deflationist *just* on the basis of holding that (2) and (3) are use-independent conceptual truths, but it may be that those theories say other things that warrant thinking of them as having inflationist correlates which they are out to deflate. Before saying another word, however, I must emphasize that I don't see that any issue worth arguing about turns on how anyone uses the word 'deflationist' (or 'minimalist'), and I do not intend in any way to disparage a theory by questioning whether it should be called deflationist. I do, however, want my use of the label to be clear.

Theories of propositional truth which are referred to as deflationist despite their holding that use determines meaning make claims in addition to those which don't on their own warrant pinning the label 'deflationist' on them, and some of these claims arguably do raise important issues possible responses to which invite an inflationist/deflationist division. I will close this chapter by briefly commenting on what I take to be the most important such issue: the issue of *truth-aptness*.

A sentence is *truth-apt* just in case it has truth-conditions (and is therefore apt for being true).[18] Truth-aptness raises the question: What must be the case in order for a sentence to be truth-apt? The question is important because certain prominent answers to it are in conflict with certain theories of the semantics of certain kinds of sentences, such as ethical sentences and indicative conditionals. The issue is of considerable concern to Field. On the one hand, his disquotationalism entails that a sentence *S* is truth-apt just in case

'*S*' is true iff *S*

is syntactically well formed, and, since

- 'Torture is wrong' is true iff torture is wrong
- 'The execution will be held indoors if it rains' is true iff the execution will be held indoors if it rains

are syntactically well formed, Field is committed to saying that ethical sentences and indicative-conditional sentences are truth-apt. On the other hand, he is sensitive to the appeal of theories which deny that such sentences are truth-apt. Field's article "Disquotational truth and factually defective discourse" (Field, 1994b/2001a) is an attempt to show that he can capture what he likes about the theories to which he is attracted in ways that are

compatible with his Radical Deflationism.[19] Frank Jackson, Graham Oppy, and Michael Smith are considerably less sanguine.

The radical deflationist's criterion for truth-aptness is an example of what Jackson, Oppy, and Smith call *syntacticism*. Syntacticism holds that:

> Truth-aptness is purely and simply a matter of syntax.… Provided the sentence can be significantly embedded in suitable constructions – for example, negation, conditional, propositional attitude and truth ascriptions – then, according to the syntacticist, that sentence is truth-apt. (Jackson, Oppy, and Smith, 1994, p. 291)

They are summarily dismissive of Field's view that truth is a property that a sentence has or fails to have independently of the way that the sentence is used by speakers, and their objection to syntacticism is that it's incompatible with the platitude that use determines meaning. More specifically, they argue that (i) a sentence *S* is truth-apt only if there is some set of truth-conditions *C* such that *S* has *C*, but (ii) there is no set *C* of truth-conditions such that a sentence has *C* just by virtue of having certain syntactical properties; truth-conditions can be determined only by "a rich enough pattern of usage" (Jackson, Oppy, and Smith, 1994, p. 293). For theorists who hold that a sentence's truth-conditions are just those of the proposition it expresses, the question

> For any sentence *S*, what must be the case in order for *S* to be truth-apt?

reduces to the question

> For any sentence *S* and proposition *p*, what must be the case in order for *S* to mean *p*?

The theories of propositional truth that are both labeled 'deflationist' and hold that use determines meaning may nevertheless hold accounts of truth-aptness that Jackson *et al.* would say are minimalist (= deflationist) accounts of truth-aptness by virtue of how little those accounts require in order for there to be a proposition that a sentence means. The only theory of this kind they discuss is one they say is held by Paul Boghossian and Crispin Wright (Boghossian, 1990; Wright, 1992) and which they call *disciplined syntacticalism*. For a sentence to be truth-apt according to disciplined syntacticalism it must have the syntactical properties required by syntacticalism, but in addition to that, they quote Boghossian as saying, the sentence's use "must be appropriately disciplined by norms of correct utterance" (Boghossian, 1990, p. 163). Jackson *et al.* call this a "minimalist" account of truth-aptness because, they claim, ethical sentences and indicative conditionals will pass its test for being truth-apt.[20] An objection one might raise to disciplined syntacticalism is that it doesn't say enough to enable us to see how standards of correct utterance determine *which* proposition a sentence means. The objection Jackson *et al.* raise to disciplined syntacticalism

> is not to what it says, but to what it fails to say. It does not say enough about a central platitude governing truth-aptness and its connection with belief.… Our contention is that there is an analytical tie between *truth-aptness* and belief, specifically, the belief of someone who asserts the truth-apt sentence. Part of the story about rich patterns of usage required to confer truth conditions must be a story about using the sentence to express belief. (Jackson, Oppy, and Smith, 1994, p. 294)

This is an objection to disciplined syntacticism because, they claim, it's possible for a sentence to pass the disciplined syntacticist's test for truth-aptness but fail to meet the expression-of-belief criterion. For in order for a state to be a belief – in the sense of 'belief' they intend (they don't deny that there is a sense in which one can say 'I believe that torture is wrong') – it must have a certain functional role, and it's not clear that the state expressed by an utterance of, say, 'Torture is wrong' has that functional role. One reason that isn't clear (they mention others) is that two views, each of which enjoys a positive degree of plausibility, are incompatible with one another. One view is the "Humean doctrine … that no belief can have a conceptual connection with motivation"; the other is that the state we would express in uttering an ethical sentence does have a conceptual connection with motivation: it's arguable, for example, that the state expressed by an utterance of 'Torture is wrong' has "a conceptual connection with being motived against torture" (Jackson, Oppy, and Smith, 1994, p. 298; see also Smith, 2016).

The disciplined syntacticist may not be without a response. Jackson *et al.* claim that it's possible for a sentence to satisfy the criterion the disciplined syntacticist says is sufficient for a sentence's being truth-apt even though uttering the sentence can't express a state with the belief-making functional role. The best strategy for the disciplined syntacticist is not to deny the functional-role criterion for being truth-apt but to argue, first, that satisfying her truth-aptness criterion entails satisfying the functional-role criterion, and, second, that a sentence's satisfying the functional-role criterion is compatible with the sentence's having the features that motivate denying that the sentence is truth-apt. For example, as regards the second part of the best strategy in the case of ethical sentences, the disciplined syntacticist might point out that Hume's doctrine isn't inviolate: nothing precludes a state from having a functional role that makes the state both a belief and a state that one can't be in unless one is also in a certain conative state; nothing, so to say, precludes 'Torture is wrong' from having a conceptual role that precludes the sentence from being tokened in one's belief box unless the sentence 'No one tortures' is tokened in one's desire box. After all, can one believe that one will now leave one's office to teach a class without intending to leave one's office to teach a class? Can one believe that one has an itch without having any inclination to scratch?[21] Now, if it can be shown that, for some proposition *p*, sentence *S* means *p*, then it should be easy to show that one who has command of *S* can be in a state that has whatever functional role is required for its being a belief that *p*. The difficult task for the disciplined syntacticist is giving *the right sort of* account of the nature of propositions generally and of the relation that must obtain between a sentence and a proposition *p* in order for the sentence, or an utterance of it, to express *p*, where the right sort of account is one that explains how little is required by way of the use of a sentence *S* in order to validate the "something-from-nothing" inference from '*S*' to 'The proposition that *S* is true,' and, correlatively, how little is required by way of the use of a predicate *F* in order to validate the "something-from-nothing" inference from '*n* is *F*' to '*n* has the property of being *F*.'[22] It remains to be seen whether the disciplined syntacticist can meet this challenge, but if she can meet it, then showing that it's met might well reveal that her position isn't very far removed from the spirit, if not the letter, of Hartry Field's deflationism.[23]

Notes

1 I use 'deflationist' where others would use 'deflationary' or 'minimalist.'

2 Field (1986; 1994a, reprinted with a new postscript in 2001a; 1994b; 2001b; 2015). Proponents of Radical Inflationism include David Armstrong, Michael Devitt, Paul Grice, Jerry Fodor, David

Lewis, Stephen Neale, Nathan Salmon, Scott Soames, Robert Stalnaker, and the time-slice of Hartry Field who wrote "Tarski's Theory of Truth."

3 'Eternal sentence' is Quine's expression for sentences whose truth-values must remain the same no matter when, where, or by whom they are uttered – for example, 'Bernard J. Ortcutt owes W. V. Quine ten dollars on July 15, 1968,' where 'owes' is stipulated to be tenseless. See Quine (1970, p. 13).

4 The radical deflationist may prefer explicit definitions of 'true_{ss}' and 'false_{ss}' that entail that they apply only to sentences I understand and that make every instance of '*S* is true_{ss}' cognitively equivalent for me to the corresponding instance of '*S*' and make every instance of '*S* is false_{ss}' cognitively equivalent for me to the corresponding instance of 'Not-*S*.' Field in effect suggests that, if we have "a theory of substitutional quantification that avoids the semantic paradoxes," then such definitions can be had by letting 'S' range over unambiguous eternal sentences I understand and then stipulating:

- *S* is true_{ss} iff $\Pi S'((S = \text{`}S'\text{'}) \rightarrow S')$
- *S* is false_{ss} iff $\Pi S'((S = \text{`}S'\text{'}) \rightarrow \neg S')$

(Field, 1994a, p. 120, fn. 17). Definitions in the same vein would also be available for the other semantic_{ss} predicates.

5 Consequently, Field mischaracterizes his deflationism when he says that "a deflationist thinks that a homophony condition guarantees that we are speaking English rather than English*" (Field, 1994a, p. 126).

6 Leeds (1978). Field emphasizes this in all the works cited in n. 2. He qualifies his claim that we need a notion of truth as a device for expressing infinite conjunctions and disjunctions by noting that substitutional quantification affords another way of expressing them (Field, 1994a, p. 120, fn. 17).

7 I am only considering how the radical deflationist might legitimate talk of the truth or falsity of foreign sentences one doesn't understand. Field claims that for foreign sentences one does understand one may simply apply one's own egocentric predicate, as it applies to every sentence one does understand. So, for example, if 'Der Schnee ist weiss' is an unambiguous eternal sentence I understand, I can say:

'Der Schnee ist weiss' is true_{ss} iff der Schnee ist weiss.

8 An indication relation is a relation between a sentence and external state-of-affairs which makes believing or asserting the sentence a reliable indication that the state-of-affairs obtains.

9 Field (1986, p. 62). Because I accept the deliverances of Google Translate, I interpret the Portuguese sentence 'Al e Betty dançou o macarena' as being equivalent to my sentence 'Al and Betty danced the macarena' – that is how I choose to interpret the Portuguese sentence. There is some unclarity in Field as to whether I can say that 'Al e Betty dançou o macarena' is true_{ss} iff Al and Betty danced the macarena or whether the most I can say is that the Portuguese sentence is true relative to Google Translate's correlation scheme iff Al and Betty danced the macarena. I have decided to use the first option throughout: otherwise (a) Field's gloss of 'pure disquotational truth' as 'true as I understand it' becomes confusing (I *understand* 'Al e Betty dançou o macarena' as equivalent to 'Al and Betty danced the macarena'); (b) it's impossible to make sense of Field's allowing that 'Der Schnee ist weiss' is for him true in the pure disquotational sense iff der Schnee ist weiss; (c) he certainly doesn't want to say that utterances of ambiguous or indexical sentences can't be true in the pure disquotational sense, but they, too, require deciding on a way of mapping such utterances onto sentences of one's mentalese; and (d) allowing that foreign sentences may be true_{ss} in this way lessens a little some of the counter-intuitive consequences of Field's theory. At the same time, I don't see that anything important turns on which of the two options one uses, since each is easily translated into the other.

10 Or I would take it to be indeterminate whether it was objectively correct or objectively incorrect, or indeterminate whether it's indeterminate whether …– but let's not get into that!

11 For a sentence to be tokened in a person's "belief box" is for it to be tokened in a state that has the functional property responsible for a state's being a belief. See Schiffer (1981).

12 Field (1994a, p. 134). Field uses 'utterance' where I use 'token'; I prefer 'token' because accounts of reference in terms of tokens lend themselves to slightly simpler formulations.

13 Field (1994a, p. 136). Field says that typically the objects he associates with the indexicals will be ones he takes "the producer of the utterance to have intended" (p. 136, fn. 31). This is somewhat misleading, however, since for Field, as we have seen, there is no objective fact as to what objects the producer intended: from Field's perspective, what intentions a person has is determined by how he, Field, decides to interpret the sentences the producer intends*.

14 Field (1994a, p. 136). Field's idea here is not that he will have a name or definite description to replace every indexical or demonstrative, but that uttered indexicals or demonstratives may be thought of as represented by subscripted mentalese indexicals or demonstratives that arise on the spot and function in processing like names.

15 My own view (1991) is that there aren't folk psychological, or even special-science, laws because if there were such laws they would have to be "*ceteris paribus*" laws, and I doubt that generalizations needing *ceteris paribus* clauses are capable of stating laws. For an opposing view, see Fodor (1991).

16 Frege (1892) and (1918); Frege called propositions 'thoughts.'

17 This puts me in agreement with Field's remark at the beginning of (1986) about where "the real philosophical problem lies."

18 Strictly speaking, we should say that a sentence is *truth-apt* just in case it's possible for tokens of it to have truth-conditions, for few of the sentence-types we utter have truth-conditions. This is obvious as regards indexical and ambiguous sentences, but it also applies to vague sentences, and virtually every sentence is vague to at least some extent. Vague sentence-types don't have truth-conditions because of a phenomenon we may call *penumbral shift*. A vague term's *penumbra* is that area of logical space wherein the term's application is anything other than unqualifiedly determinately correct or unqualifiedly determinately incorrect. The penumbra of a vague term may shift somewhat from one context of utterance to the next, and these shifts entail shifts in the term's application conditions, so that, for example, 'bald' is true of Harry in one context of utterance, false of him in another, and neither determinately true nor determinately false of him in still another context of utterance. In this way, tokens of the sentence 'Harry is bald' produced in those three contexts will have somewhat different truth-conditions from the other two tokens. Having said that, however, I'm going to ignore it and join Jackson *et al*. in simply speaking of a sentence's truth-conditions.

19 The article also discusses vague discourse and discourse involving referential indeterminacy as other kinds of "factually defective" discourses that might appear to be in conflict with Radical Disquotationalism.

20 It's actually not clear that ethical sentences will be truth-apt on such expressivist theories as emotivism or R. M. Hare's prescriptivism (see, e.g., Hare, 1952). For on these theories, there are no norms of correct utterance to legislate between competing ethical claims, nothing one can say to the Nazi who says 'Jews ought to be exterminated' to prove to him that he is wrong. Jackson *et al*. do say that "some might quarrel with the claim that the [norms of correct utterance] are firm enough in the ethical case," but the "some who might quarrel" can't be emotivists or prescriptivists, for their position is quite clear that on their views no ethical judgment can be objectively correct or incorrect (when one protests to the Nazi that his claim isn't correct, all one is doing is countering one emotive or prescriptive utterance with another).

21 See Schiffer (2003, ch. 6), Michael Smith's (2016), and Schiffer (2016), which is a response to Smith.

22 In (Schiffer, 2003, p. 61) I explained that we have a something-from-nothing inference "when from a statement involving no reference to an *F* we can deduce a statement that does refer to an

F …. [For example,] from the statement 'Lassie is a dog', whose only singular term is 'Lassie', we can validly infer the pleonastic equivalent 'Lassie has the property of being a dog', which contains the new singular term 'the property of being a dog', whose referent is the property of being a dog."

23 I'm indebted to Hartry Field for his very helpful comments on a previous draft of this chapter.

PART I

Language, Truth, and Reality

20

Realism and its Oppositions

BOB HALE

In many branches of philosophy, dealing with very different areas of our thought and talk, there occur disputes centered on the tenability of positions described as 'realist.' In the philosophy of science, realism stands opposed to various forms of instrumentalism; mathematical realists, often known as Platonists, are opposed in one way by nominalists, in another by constructivists; moral realists contend with subjectivist tendencies, such as expressivism and projectivism, as well as with error theories; in the theory of meaning itself, realism is under attack from positions which hold that meaning must be explained in terms which preserve an essential link between what we mean and evidence, as well as from meaning-skeptical arguments advanced by Quine, Kripke, and others (see Chapter 26, INDETERMINACY OF TRANSLATION; Chapter 23, ANALYTICITY; Chapter 31, MODALITY, §2; Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING; and Chapter 27, PUTNAM'S MODEL-THEORETIC ARGUMENT AGAINST METAPHYSICAL REALISM). It is scarcely obvious that there is some single type of issue at stake in these disputes (henceforth R/AR disputes), or that there is at least some significant continuity between them. The very diversity of the positions set against realism in these different areas might of itself be thought to point towards the opposite conclusion: that realism amounts to different things in the different cases, so that any attempt at general discussion is doomed to failure. It is not obvious, either, that the various disputes have anything much to do with the philosophy of language, or that there is any reason to expect arguments in the philosophy of language to play a significant part in their resolution.

Against these dampening thoughts may be set – besides the feeling that it is unlikely to be sheer coincidence that the same label is applied to completely disparate positions with no significant similarities whatever – at least two reasons why philosophers of language may properly take an interest in general questions about realism and the forms which opposition to it may assume. First, and most obviously, there is an R/AR dispute (or disputes) within the philosophy of language itself, centered on the tenability of realist theories of meaning. At the very least, it might be expected that scrutiny of R/AR disputes in other areas may

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

illuminate the issues here, if only through contrasts rather than parallels. But second, and more importantly, the notion that debates about other realisms – in science, mathematics, or other areas – may proceed unaffected by arguments in the philosophy of language overlooks the possibility that a successful anti-realist argument in the theory of meaning may ramify into other disputed areas (see Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING, §3).

We begin (§1) with an examination of Michael Dummett's influential treatment of these issues, which couples an attempt to identify a common form exemplified by a large, if not exhaustive, range of R/AR disputes with important arguments against a realist position about meaning which – if they are sound, and Dummett's diagnosis of what is at stake in those disputes is correct – promise to resolve the issue in the anti-realist's favor, not only in the theory of meaning itself, but across the board.[1] We then (§2) survey the principal negative arguments, advanced by Dummett and others, for semantic anti-realism. In §3, we turn to the wider question of the bearing of these arguments on R/AR disputes more generally, and review doubts about the adequacy of Dummett's general conception of their common form. Other ways in which the anti-realist case may be prosecuted are reviewed in §4: classical reductionist positions; error theories; expressivist/projectivist options and quasi-realism; and we conclude (§5) with a brief examination of the new perspective on R/AR disputes advocated in recent work by Wright.

1 Dummett's General Account of R/AR Disputes

Many traditional, and at least some currently active, R/AR disputes appear primarily to concern the existence of entities of some sort – objects of some general type, or perhaps entities which, if there are such, should be taken as belonging to some other category. Medieval realists and their nominalist adversaries, for example, were disagreed over the existence of universals – abstract entities conceived as objective worldly correlates of general terms like 'red' and 'honest' and denoted by corresponding abstract nouns like 'redness' and 'honesty.' The cardinal negative thesis of many modern nominalists has likewise been the denial that there exist any abstract entities – by which they chiefly understood properties or attributes, as opposed to the particular concrete entities they characterize, together with sets or classes. One kind of realism or platonism about mathematics is distinguished by its acceptance of numbers and sets as genuine objects, lying outside space and time but nonetheless existing independently of our thought. At least part of what is in dispute between scientific realists and their opponents is whether a satisfactory account of theoretical science requires us to see it as describing the properties of unobservable or theoretical entities such as particles, forces, and fields. Modal realists of one sort insist that there are possible worlds, distinct from but no less real than the actual world. (See Chapter 31, MODALITY, §3.)

Dummett's conception of R/AR disputes stands in sharp contrast with the model suggested by such examples. Issues between realists and their opponents are, he contends, usually best characterized *not* as disputes about the *existence of entities* of some problematic sort, but in terms of a certain *class of statements* – those distinctive of the area of thought and talk in question – which he usually labels the 'disputed' class. Further, the disagreement is not – or not primarily – over whether statements of the disputed class are true, since the anti-realist will agree that in many cases they are so; it concerns, rather, the nature or

character of the notion of truth which may be applied to them. This last point merits both emphasis and comment. A preference for formulating R/AR disputes in terms of problematic statements rather than problematic entities need, by itself, involve no significant break with the idea that those disputes centrally concern the existence of entities of certain kinds. It need not do so, because the preference might be grounded in the plausible view that general ontological questions (Do there exist so-and-sos?) reduce to, or are at least best approached as, questions partly about the logical form of some appropriate range of statements and partly about their truth-values. Thus one question at issue between mathematical Platonists on the one side and, on the other, nominalists and others is whether numbers, sets, and so on exist. Precisely because we are obviously not concerned with entities which might conceivably be objects of ostension or of any sort of perceptual encounter, or which might announce their presence indirectly through their effects, it is difficult to see how the question of their existence can be non-prejudicially approached, save by equating it with a question about truth and logical form: Are there true statements whose proper analysis discloses expressions purporting reference to numbers? General endorsement of this approach to questions of ontology is tantamount to acceptance of Frege's celebrated 'Context Principle' which, construed as a principle about reference, warns against asking after the reference of sub-sentential expressions outside the context of complete sentences (Frege, 1884, p. x and §62; Dummett, 1973a, pp. 192–196, 494–500; 1982, p. 239; 1991, chs 16 and 17; Wright, 1983, §§2, 3, 5, 8; Hale, 1987, pp. 10–14, 152–162, 228–230). Dummett is sympathetic to it. But his insistence upon treating R/AR disputes as centered on a class of statements is prelude to a quite different claim about their character. He writes:

> Realism I characterise as the belief that statements of the disputed class possess an objective truth-value, independently of our means of knowing it: they are true or false in virtue of a reality existing independently of us. The anti-realist opposes to this the view that statements of the disputed class are to be understood only by reference to the sort of thing which we count as evidence for a statement of that class … The dispute thus concerns the notion of truth appropriate for statements of the disputed class; and this means that it is a dispute concerning the kind of *meaning* which these statements have. (Dummett, 1963, p. 146)

As Dummett goes on to make clear, he thinks that the notion of a statement's having an 'objective truth-value, independently of our means of knowing it … in virtue of a reality existing independently of us' is to be understood in a very strong sense. The realist is to be understood as holding not merely that a statement may be true or false without our actually knowing its truth-value, nor even that a statement may be true or false even though we are in fact or in practice unable to tell which, but that there can be a much more radical dislocation of truth-value and our capacity for its recognition – a statement may possess a determinate truth-value without its being possible, even in principle, for us to come to know it (Dummett, 1963, p. 146; 1969, p. 358; 1973b, p. 224; 1982, p. 230). It is for this reason that realism, as Dummett conceives it, amounts to – or at least crucially involves – a thesis about meaning: to adopt a realist view of any area of thought and talk is to conceive of its distinctive statements as endowed with meaning through being associated with evidentially unconstrained truth-conditions, that is, conditions whose satisfaction bears no essential connection, however attenuated, with the possibility of its being recognized by us.

Although the foregoing characterization may be taken as definitive, Dummett very frequently depicts the issue between realists and their opponents in other, ostensibly quite

different terms, as concerning the principle of bivalence, according to which every statement is either true or false.[2] It is clear that in taking endorsement of unrestricted bivalence as 'a touchstone for a realistic interpretation of the statements of some given class,' Dummett intends no departure from his official characterization. The relations between the two are, however, by no means straightforward. It is, certainly, very plausible to regard unqualified endorsement of bivalence as *sufficient* for realism. For it is a plain fact that our language affords the means of framing various kinds of statement which are not effectively decidable – that is, statements for which there exists no procedure guaranteed to issue, after finitely many steps, in a correct verdict on their truth-values. To insist that such statements are, nevertheless, determinately either true or false would, it seems, require thinking of them as capable of being true, or false, in the absence of evidence either way, and thus as possessed of potentially evidence-transcendent truth-conditions. But realism does not obviously entail a commitment to unrestricted bivalence. It seems that one might decline to endorse bivalence for reasons which appear quite consistent with holding that certain statements may have their truth-values undetectably, say because one took failure of reference on the part of ingredient singular terms to deprive statements of truth-value.[3] A further complication concerns vagueness, which is commonly – though not invariably – taken to cause certain statements to lack determinate truth-value (see Chapter 28, SORITES). These considerations indicate that refusal to endorse bivalence may or may not signal adoption of an anti-realist view, depending upon the specific reasons for that refusal. If realism does involve a commitment to bivalence, it would seem that it can be at most a conditional one, to the effect that any statement is true or false whose ingredient terms are not subject to vagueness or reference-failure. Whether and how this qualified claim can be established, and, in particular, how it might be shown that vagueness and reference-failure are the only grounds on which a realist may properly refuse to endorse bivalence, are hard questions to which, so far as I know, we still want answers. Here they must be left open.

There are, as we have observed, many different areas in which what seems aptly described as a realist position may be defended or opposed. There is no clear presumption that one must be committed to realism across the board, if one seeks to uphold a realist position in any quarter of it. On the contrary, it appears that realism in one area might consist perfectly well with opposition to it in another – that one might, for instance, defend a realist view about theoretical science whilst rejecting realism about ethics, or values generally, or, even more selectively, combine a realist attitude towards some parts of scientific theory (such as classical physics) with anti-realism about other parts (such as quantum mechanics). Certainly there appears little prospect of a quite general argument enforcing adoption of a globally realist stance. A considerable part of the interest and importance of Dummett's configuration of R/AR disputes undoubtedly lies in the fact that it opens up the possibility – which might otherwise appear no less remote – of a quite general argument of the opposing tendency, enforcing global anti-realism across all the disputed areas. For if Dummett is right, realism everywhere depends upon the viability of a realist conception of meaning in terms of potentially evidence-transcendent truth-conditions (hereafter, 'realist truth-conditions' for brevity). Thus any argument against semantic realism as such is potentially quite generally destructive of realist options. There are, accordingly, two main questions requiring attention: (1) Are there compelling arguments – perhaps ones advanced by Dummett himself – against a realist conception of meaning? (2) Has Dummett provided an adequate general characterization of R/AR disputes? In the 50 or so years since Dummett's

earliest publications that bear on them, both questions have generated a very considerable amount of critical discussion, of which only the briefest overview can be given here.

2 Arguments against Semantic Realism

Dummett himself advances two main arguments against the idea that our understanding of disputed statements could consist in our associating them with realist truth-conditions, one focused on the difficulty of seeing how we could *acquire* such an understanding, and the other on the difficulty of seeing how we could *manifest* it. As will quickly become apparent, neither argument purports to be conclusive: each is, rather, to be seen as presenting the realist with a challenge which she appears unable to meet.

According to the *Acquisition Challenge*, our training in the use of language consists in our being taught to accept statements as true in circumstances of such-and-such a sort, and to reject them as false in circumstances of other sorts. This training *necessarily* proceeds in terms of states of affairs which we can *recognize* as obtaining. But how, in that case, are we supposed to come by the conception of evidence-transcendent truth-conditions which the realist postulates? How are we to come to know what it is for a statement of that kind to be true, or false, in virtue of the obtaining of some state of affairs which obtains *undetectably*? The challenge is to explain how we come to assign to statements truth-conditions involving states of affairs which, by their very nature, *can have played no part* in the process by which the meanings of those statements are learned or communicated. If it is conceded that there can indeed be no *ostensive* training that enables us to form such a conception, but suggested that we can nevertheless acquire it through *verbal explanation*, the counter may be given that this merely postpones the problem, since presumably no verbal explanation can be adequate that does not itself employ sentences already understood as having evidence-transcendent truth-conditions – but in that case, how is the proposed explanation to get off the ground?[4]

The *Manifestation Challenge* runs thus: If the meaning of a statement consists in its having certain (possibly evidence-transcendent) truth-conditions, then understanding it (knowing its meaning) is possessing knowledge of such. But knowledge of a statement's meaning cannot, in general, consist in the ability to provide an informative statement, in other words, of what it means (and obviously it can't consist in the ability to state *un*informatively what it means, just by disquoting it). We may concentrate on the case where knowledge of meaning does not consist in the capacity to give a verbal explanation of meaning, since no such explanation can introduce the possibility of evidence-transcendence. When knowledge of meaning is not verbalizable but implicit knowledge, it must be knowledge of how to use the sentence, and must therefore consist in the speaker's possession of certain practical abilities. But now, by just what practical abilities is an alleged grasp of evidence-transcendent truth-conditions supposed to be manifested? In the case of effectively decidable statements, or of statements which, whenever they are true, are recognizably so, a speaker's implicit knowledge can be identified with his capacity to discriminate between circumstances in which the statement is true and those in which it is not. But it clearly cannot do so in the case of any statement possessed of evidence-transcendent truth-conditions – in this case, there is nothing a speaker can do which fully manifests his supposed grasp of those conditions. Realism thus clashes head-on with the Wittgensteinian equation of meaning with use and of understanding with capacity for correct use.[5]

Attempts to Answer the Acquisition Challenge

Truth-Value Links

Among the types of statement that are problematic, in view of the anti-realist challenge, are statements about the past and about other minds. The realist conception has it that such statements can be determinately true or false in virtue of past states of affairs, or states of mind of others, to which we have no direct access, and for which adequate evidence may be quite simply unavailable. And the challenge is then to explain how we come by this conception. One suggestion is that the truth-values of statements of these problematic kinds are systematically connected with those of statements lying outside the anti-realistically problematic class – in these cases, present-tensed statements and first-person psychological statements. Thus there is a systematic link between the truth-value of a past-tensed statement made at one time, say now, and various corresponding present-tensed statements which were, or could have been, made at earlier times; for example:

> The statement: 'One million years ago, this place *was* covered with ice' is true now if and only if the statement 'This spot *is* covered with ice,' made a million years ago, was (or at least would have been) true.

The thought, then, is that understanding this truth-value link is an uncontroversial component in our mastery of tensed discourse. But present-tensed statements are not, as such, anti-realistically problematic, since they relate to conditions which obtain (or don't, as may be) detectably or recognizably. By our grasp of these two things, it is claimed, we can come to understand what it is for past-tensed statements to be true in virtue of states of affairs which are no longer accessible to us.[6]

This response fairly obviously fails to provide a *general* answer to the acquisition challenge, since no such maneuver appears feasible in the case of other types of problematic statement, such as unrestricted quantifications over an infinite, or otherwise unsurveyable, totality of objects, such as the natural numbers. Of course, '∀nPn' is true iff all its instances are true. But this is clearly no advance, since whilst the truth-value of each 'Pn' may be unproblematically recognizable, if 'P' is a decidable arithmetic predicate, we enjoy no unproblematic access to the fact, if it is one, that *all* of them are true.[7] But even in cases where the truth-value link gambit appears available, it does not really work. The trouble is that present-tensed statements have unproblematic (detectable) truth-conditions *only in the context of present use*. But the link only helps if we understand what it means to say, for example, 'This spot is covered with ice' *was* true; that is, what is *ceteris paribus* unproblematic is what it is for a present-tensed statement to be *true now*, but what we need, to move from right to left across the truth-value link to knowledge of what it is for a past-tensed statement to be now, but undetectably, true, is understanding of what it is for a present-tensed statement *to have been true* – and this is no less problematic than what we are seeking to explain.[8]

Partial Accessibility

We can distinguish between *chronically e-transcendent* statements – such as 'Everything in the universe has doubled in size' and 'The entire universe sprang into existence just five minutes ago, replete with traces of a long and complex past, etc.' – which by their very nature could in no possible circumstances be recognized as true, and statements which,

though not *guaranteed* to be so, are, *in favorable cases*, *detectably* true. Realists may concede that there is no hope of defending their distinctive conception of truth for the former, though claiming that this is no loss, since they are beyond the pale anyway; but they may insist that matters stand otherwise with the latter. Here, they may claim, if a statement of this sort is undetectably true, it is at most *contingent* that it is so. Statements of the same kind are, on occasion, recognizably true: that is, we sometimes have access to states of affairs of the kind which confer truth on them. And this, they may claim, is enough – enough to equip us with a conception of what it is for such statements to be true but undetectably so – this is just for there to obtain a state of affairs of the same kind as we have recognized to obtain in other cases. So it is, McDowell claims, with statements about the past and about the psychological states of others. Although we don't always, or even usually, have direct non-inferential access to past states of affairs, we do sometimes, through memory; and we can on occasion simply and literally observe that another is in pain or violent grief – we may see pain or grief in their face and actions, which express or manifest their state.[9]

Like the preceding response, this is of limited application at best. It is doubtfully available in the case of statements about the remote past, beyond the reach of living memory. Further, no response of this sort seems available for spatially or temporally unrestricted contingent generalizations (whether lawlike or accidental), or for quantifications through an infinite domain – in neither case does there appear to be any purchase for the idea of our being sometimes graced with direct access to an appropriate truth-conferring state of affairs. Clearly, too, the idea of occasional direct access to others' psychological states may be challenged. But there is a quite general difficulty with the partial access gambit, even in what might seem favorable cases.

First, and obviously, we should distinguish between the (problematic) case of a statement's being *undetectably* true and the (unproblematic) case of a statement's being true, though not, as it happens, known to be so, simply because we haven't taken steps we could have taken to ascertain its truth-value. We can, plausibly, understand what it is for a statement in the latter case to be true, in terms of there obtaining a state of affairs of the same kind as we have verified to obtain in the case of other statements of that type. But this is not to the point – for it is another, and much stronger, claim that we can come by the notion of undetectable truth by this route.

Second, with this out of the way, we can see that the crucial, but contentious, claim is that statements in respect of which we do *not* enjoy direct access to any truth-conferring state of affairs are *of the same kind* as other statements, such as those about the past, for which we do. Once it is allowed that they *are* of the same kind, it may seem an easy step to the realist's desired conclusion, that we can conceive of the former as true in the same way as the latter, for all that the former are, as it happens, undetectably true. Now they *are* of the same kind in one sense, for they are all statements *about the past*. But this, the anti-realist may protest, is not the point. In another sense, they are *not*: for the former are (allegedly) undetectably true, if true, whereas the latter are, *ex hypothesi*, detectably so. The realist simply *assumes*, but does nothing to show, that this difference *makes no difference*. But that it does make a difference is precisely the content of the acquisition challenge. So the question is begged, not answered.[10]

Enhanced Recognitional Capacities

The idea that underpins the preceding response, that undetectability of truth-value commonly derives from contingencies of our circumstances or contingent limitations upon our recognitional capacities, is sound enough. There may be some temptation to think it can be

exploited to the realist's advantage in a somewhat different way. It may be suggested that we can attain a conception of what it is for statements to be true – though *undetectably* so as far as *we* are concerned – by conceiving of creatures with suitably extended powers of recognition, for whom the obtaining of the relevant truth-conferring states of affairs would *not* be undetectable. Thus far, the moderate anti-realist need have no objection – indeed, unless he is able to appeal to conceivable finite extensions of our powers of recognition, computation, and so on, it is hard to see how he might resist the slide into an implausibly extreme version of anti-realism (strict finitism, in the case of mathematics), according to which the only meaningful statements are those which we can actually verify.[11] But if the suggestion is to serve the realist's ends, it must go beyond envisaging relatively uncontroversial, finite extensions of our detective abilities, to encompass conceiving, for example, of creatures capable of surveying infinite totalities, or 'directly seeing' into the past and future, or into the minds of others. It is not, however, at all clear that we can conceive any such thing in relevant detail – it is one thing to appeal to the idea of creatures whose recognitional capacities *finitely* extend powers we *actually* possess, and quite another to claim that we can conceive of creatures endowed with capacities for which we have *no* actual model, or which constitute *infinite* extensions of our capacities. It may further be objected that even if we could imagine a use for certain sentences, by beings with powers greatly exceeding our own, this does not automatically put us in a position to use those sentences in that way ourselves. To suppose that we could is to suppose that we could employ those sentences with the intention of conforming to standards of correct use, even though we are ourselves entirely unable to tell whether our use accords with them or not. This seems to run afoul of considerations concerning the *normativity* of meaning. To attach a certain meaning to a statement is, in effect, to divide states of affairs into two classes: those in which it is correct to assert the statement, and those in which it is incorrect. To employ the statement with that meaning is, prescinding from complications about insincerity, to use it with the intention of asserting it only in states of affairs of the first kind. But it appears quite generally to make no sense to suppose that an agent intends to φ if there is in principle no means available, however indirect, of telling whether or not he has succeeded in φ-ing. So in particular, nothing can be made of the suggestion that we intend, in using certain statements, to conform to standards of correctness in use, conformity with which essentially eludes detection *by us*.[12]

Compositionality

A better response might begin by pointing out that the opening claim of the acquisition argument – that our training in the use of language consists in our being taught to accept statements as true in circumstances of such-and-such a sort, and to reject them as false in circumstances of other sorts – is liable to deflect attention from the crucial point that our understanding of most sentences comes not through any directly forged link between them and recognizable states of affairs in which their assertion is justified, but is the product of prior understanding of their ingredient expressions together with their mode of construction. It may then seem that a very simple response is available: we come by a grasp of realist truth-conditions by coming to understand sentences having those truth-conditions, and we come to understand such sentences in just the way in which we come to understand the vast majority of sentences in our language, by understanding their ingredient words and semantically significant syntax.

The anti-realist must indeed accept that our understanding of sentences of the various kinds central to the dispute – statements about remote regions of space or time, quantifications

through infinite or unsurveyably large totalities, counterfactual conditionals, and so on – is, in general, acquired along compositional lines. But he will likely object that the further claim – that that understanding involves the association with those sentences of realist truth-conditions, rather than, say, conditions of justified assertion – is entirely gratuitous. The realist may, and should, concede that the proposed response does not *prove* that we understand the problematic sentences as having realist truth-conditions. But she can point out that it was not intended to do so; the aim was rather to explain, on the *assumption* that our understanding has that character, how we may have acquired it. In the absence of an argument showing that a grasp of realist truth-conditions cannot emerge, via composition, from agreed unproblematic starting points, or an independent argument – perhaps one based on manifestation – for the bankruptcy of the distinctive realist conception of truth-conditions (of which it would be a corollary that we cannot have acquired it), it seems that this is enough to neutralize the acquisition challenge.

Attempts to Answer the Manifestation Challenge

Explanatory Ascription

Several critics claim that the manifestation challenge may be met, or deflected, by observing that the ascription of knowledge of realist truth-conditions may form part of a successful theoretical explanation of speakers' behavior. A closely related suggestion is that knowledge of meaning is manifestable in a capacity to interpret the speech-behavior of others, where this involves, centrally, the correct ascription of beliefs – which may be realist beliefs – which figure, in combination with suitable desires, in explanations of speakers' behavior.[13] But there is an obvious difficulty with this kind of response. Evidently there is no reason why an anti-realist should not go in for interpretations of linguistic behavior, or explanations of behavior in general, in terms of beliefs. It is therefore essential to show, if the proposed reply is to make headway, that such interpretations and explanations must sometimes proceed in terms of specifically realist beliefs.[14] That is, it needs to be indicated what specific aspects of behavior, or the capacities to which they bear witness, call for explanation in terms of the hypothesis that the subjects of ascription hold beliefs, the content of which demands characterization in terms of realist truth-conditions rather than conditions of warranted assertibility, say; otherwise, the ascription of realist beliefs will merely incorporate so much theoretical slack.[15]

Inferential Practice

It may be suggested that a realist understanding of certain statements may be manifested by our employment of distinctively classical principles of reasoning in our willingness to reason by (unrestricted) use of the Law of Excluded Middle, or by Double Negation Elimination, or other patterns of inference rejected by the intuitionists and unjustifiable save on the assumption that the statements are apt for evidence-transcendent truth.

A difficulty with this is that it involves treating our actual inferential practice as sacrosanct. As against this, it may be said that the justification for employing certain principles of inference should be given in terms of the kind of meaning we have conferred upon the statements involved, so that the appeal to inferential practice gets things the wrong way round. Why should we take our unrestricted use of classical logic as showing that we have conferred realist meanings for the sentences involved, rather than as revealing that we have – by a kind of uncritical inertia – illegitimately projected patterns of reasoning that are

correct within a restricted domain (say, of decidable statements) to cases which lie outside it? Even if it is granted that a propensity to reason classically betokens a *commitment* to assigning realist truth-conditions to problematic statements, it does not seem that this could suffice to make clear what specific truth-conditions have, putatively, been assigned to them.[16]

Other Modes of Manifestation?

In case of decidable statements, a speaker may manifest a grasp of truth-conditions in a quite straightforward way, by implementing the appropriate procedure, leading to her recognition of the statement as true, or false, as may be. Where a statement is not effectively decidable, and is in fact true but not recognizably so, a speaker cannot, obviously, manifest a grasp of its truth-condition by determining its truth-value. But the thought is tempting that she may nevertheless demonstrate an appropriate understanding in other ways. Thus Strawson (1977, p. 16) proposes that whilst it is, of course, true – and a truism – that 'grasp of the sense of a sentence cannot be displayed in *response* to unrecognizable conditions,' it will be

> enough for the truth-theorist that the grasp of the sense of a sentence can be displayed in response to *recognizable* conditions – of various sorts: there are those which conclusively establish the truth or falsity of the sentence; … those which (given our general theory of the world) constitute evidence, more or less good, for or against the truth of the sentence; … even those which point to the unavoidable absence of evidence either way.

His thought is that there are various responses to recognizable states of affairs which can be regarded as manifesting a grasp of the sense of a sentence, in addition to recognizing that the condition for its truth definitely does, or definitely does not, obtain.

So there surely are, but this does not seem enough. Here it is crucial to remember that the truth-theorist to whose defense Strawson is (or ought to be) contributing is a realist, who holds that grasp of the sense of a sentence consists, in the case where the sentence is not effectively decidable, in knowledge of its possibly e-transcendent truth-condition. The responses Strawson mentions, however, are entirely consistent with the anti-realist view that, in such cases, understanding the sentence consists in knowing the conditions for its warranted assertion. That is, such responses do not distinctively display grasp of *realist* truth-conditions for the sentence.[17]

Manifestation and Manifestees

Manifestation is a relational matter. A chess master may be able to manifest her skills to others with a reasonable knowledge of the game; but she cannot be expected to display all or even any aspects of her virtuosity to those unfamiliar with it. Simon Blackburn claims that the manifestation argument only appears compelling because it tacitly restricts the manifestees to cognitively impoverished creatures, capable only of *observation*. Thus, picking up on Dummett's remark that 'an individual can communicate only what he can be observed to communicate' (Dummett, 1973b, p. 217), Blackburn takes this to suggest that the manifestee is to be

> one who is capable of making observations, but no more. But let us suppose that some things lie outside observation: the past, or other people's sensations, or sub-atomic particles. Then it is clearly not a sensible requirement that a man should manifest his understanding of these

> things to someone who is capable of only making observations.… Such limited observers make poor audiences…. the very word 'manifest' reveals the doubtful nature of this requirement. Like 'display' and 'reveal,' it has largely visual overtones: I cannot display or make visible the past events I talk about, the future ones, my own pains and thoughts, let alone electrons or numbers. (Blackburn, 1984, pp. 65–66; 1989)

But this complaint, it seems to me, misrepresents Dummett's argument. That an anti-realist imposes no restriction to states of affairs which can be observed to obtain, when they do, should be clear from the mathematical case which forms the departure point for his work. Dummett raises no problem about finitary mathematical statements, although their truth, if they are true, plainly does *not* consist in the obtaining of some *observable* state of affairs. The important distinction is not between the observable and the unobservable, but between effectively decidable statements and others. In the case of any statement whose truth or falsity is an effectively decidable matter, we can equate implicit knowledge of the statement's truth-condition with a capacity to decide it. The case where the statement concerns some literally observable state of affairs is just a special case of this – here there is a particularly simple decision procedure: just look and see (sniff and smell, and so on). It is with non-effectively decidable (non-ED) statements that the problem arises: their being non-ED does not, of course, mean that there cannot be circumstances in which we are able to tell that the condition for their truth is fulfilled or not. Thus to take a famous example, if Goldbach's Conjecture that every even number is the sum of two primes is false, we might one day be confronted with a counter-example; and there is no reason to suppose that, if it is true, it is nevertheless insusceptible of proof – so we could conceivably be in position to recognize it as true. The point is that we have no effective way of bringing about a situation of either kind. It is for this reason that we cannot equate a knowledge of the statement's truth-condition (as the realist conceives it) with a capacity to recognize a proof of it, or a counter-example to it, should we be lucky enough to find ourselves confronted with such. For then the statement would be true if and only there is a proof of it, and false if and only if there is a disproof. But there is no guarantee that a situation of either kind will ever obtain, so the realist could not be justified in taking it that the statement is true or false all the same (cf. Dummett, 1976, pp. 81–82).

In particular, the suggestion that talk of what can't be made visible – such as numbers – is threatened by the manifestation requirement quite misconstrues its intended force. What has to be capable of manifestation is our supposed knowledge or understanding, not the objects we talk about. If Blackburn's reading of Dummett were right, he ought to find *all* statements about numbers problematic. But of course, he does not: there is no special difficulty in saying what (implicit) knowledge of the truth-condition for example '937 is prime' consists in – it consists in mastery of a procedure for deciding the statement.

Blackburn's key claim – that the argument relies on some unduly restrictive assumption about the capacities of suitable manifestees – is thus indefensible as a reading of Dummett's texts. It might nonetheless be claimed that the argument has plausibility only under some such restriction. But is that so? Let's suppose the audience is as competent in the use of the statements in question as the speaker. That is, grant what Blackburn would reckon as a suitable audience – someone competent in number theory, say. We can still ask: What recognizable capacities of the speaker constitute his supposed knowledge of what it is for statements involving unbounded quantification over the natural numbers to be true, but undetectably so? Bringing in a suitable audience appears in itself to make no advance on

the problem – we still need an answer to the question (cf. Wright, 1993a, pp. 20–21). This discussion of the principal anti-realist arguments has been quite selective,[18] and is, it will be only too clear, inconclusive. My aim has been limited to providing little more than an introductory survey of some of the main moves made in this complex, difficult, and, in my view, still unresolved debate.

3 The Adequacy of Dummett's Characterization of R/AR Disputes

If Dummett's account of R/AR disputes in general is acceptable, the potential bearing of anti-realist arguments in the theory of meaning upon their resolution is immediate: if successful, such arguments would enforce a globally anti-realist stance. But is it acceptable? Dummett has never maintained that his characterization fits *every* dispute which might be taken to concern the tenability of position describable as realism (cf. Dummett, 1963, pp. 146–147). His claim has rather been – and continues to be – that it captures what is centrally at issue in an extensive range of such disputes. Few would deny that there are cases to which Dummett's characterization seems entirely apt. The dispute between Platonists and constructivists in the philosophy of mathematics is probably the clearest example. Platonists in this sense uphold – and various species of constructivist challenge – the legitimacy of employing in mathematical reasoning forms of inference enshrined in classical logic, such as Double Negation Elimination and a strong form of *reductio ad absurdum*, which depend for their justification upon the assumption of unrestricted bivalence, and hence upon taking mathematical statements to have realist truth-conditions. But it may be doubted whether the same is true of other R/AR disputes which have commanded interest and attention in recent and ongoing philosophical discussion.

We can distinguish three component claims in Dummett's configuration of R/AR disputes:

1. such disputes are best understood as concerned with a class of problematic *statements*, rather than with a class of problematic *entities*;
2. more specifically, what is in dispute is the *character* of the notion of *truth* which may properly be taken to have application to the statements in question;
3. more specifically still, what is primarily at issue is whether statements of the kind in question may defensibly be held to be capable of being true in a *potentially evidence-transcendent* manner.

Clearly each of these claims presupposes the correctness of – and is, in that sense at least, stronger and more contentious than – its predecessors. Our review of grounds on which the adequacy of Dummett's approach may be doubted can conveniently be organized in terms of them. We begin with some considerations relating to the first claim.

In one of his most recent papers on the present topic,[19] Dummett reiterates his conviction that R/AR disputes are best seen as concerning a class of problematic statements, rather than a class of problematic objects, and offers two reasons for it. The first is that in some cases – the examples given are disputes over the reality of the past or over the future – there is no germane class of objects for the dispute to be about. The second is that even in cases where there is some problematic type of object, as with the Platonist/constructivist dispute

about mathematics, it is not the existence of the objects as such that the dispute really concerns, but the objectivity of the statements we make about them. A philosopher who accepts a problematic class of objects – numbers or sets, for example – may yet take an anti-realist view of facts about them; while one who takes objects of that kind to be mind-dependent, perhaps because he views them as products of our intellectual activity, much as Dedekind viewed numbers as our 'free creations,' may yet be a realist, in Dummett's sense, about truths concerning them (as Dedekind appears to have been). The significant difference, Dummett claims, is between those who hold that mathematical statements, say, have determinate truth-values independently of our capacity to ascertain them, and those who deny this (Dummett, 1963, pp. 145–147; 1993a, pp. 464–465).

It is natural to protest that, unless it is intended merely as a forceful expression of Dummett's own greater interest in one kind of disagreement than another, the claim that *the* significant difference concerns one's attitude towards recognition-transcendent truth-value is tendentious. It is, of course, *a* difference, and an important one. But granting that much is perfectly consistent with acknowledgement that the disagreement between Platonists and nominalists over the existence of numbers, sets, and other kinds of abstract objects centers upon another, equally significant difference, reflecting a different aspect of R/AR disputes. More generally, it is an indisputable historical fact that some R/AR disputes are, at least in part, disputes about the existence of one or another kind of problematic entity. Obvious examples, besides the Platonist/nominalist dispute just mentioned, are the disagreements between realists and their opponents in the philosophy of science over the existence of unobservable entities postulated in advanced scientific theories, and in the philosophy of modality over the existence of possible worlds. The present point is that, even if such disputes are in part about evidence-transcendence, they involve ontological disagreements as well. If neglect of the latter aspect is indeed a consequence of Dummett's reconstruction, that is surely a serious limitation.

In fact, matters are less straightforward than these remarks suggest. Striking a more concessive note, Dummett suggests (1963, p. 147) that a dispute over the existence of certain entities might be represented in his way – that is, as concerned with a problematic class of statements – simply by taking the disputed class to consist of statements purporting reference to those entities. This suggestion accords well with the view briefly adumbrated above (Dummett, 1963, p. 273; cf. also Wright, 1993a, pp. 8–9) that ontological questions are best treated as questions about the logical form and truth-values of some appropriate range of statements. The possibility of thus reconfiguring questions about the existence of entities of some kind as questions about a certain suitably chosen range of statements is certainly enough to show that, if Dummett's approach does indeed involve an unwanted neglect of ontological issues, that is not a defect for which claim (1) is to be held responsible. But that is not, on the face of it, enough to dispose of the charge altogether. For the questions relevant to resolving the ontological issue – questions about the logical form and truth-values of certain statements – are, it seems, quite distinct from those upon which, in line with claims (2) and (3), R/AR disputes should, in Dummett's view, be concerned – questions about the character of the notion of truth applicable to statements in the disputed class. As against this, it might be claimed that what is typically at issue in a philosophical dispute about the existence of entities of some kind is not simply whether or not there are such things as numbers, say, or colors, but whether the entities in question enjoy an objective existence, independent of our thought and talk of them. But the question whether objects of some sort are objective or mind-independent – or so it may plausibly be held – is best

regarded as being whether statements purporting reference to those objects are capable of objective, mind-independent truth. Thus questions about the character of the notion of truth having application within the appropriate range of statements are, after all, central to ontological disputes, and the charge that Dummett's approach entirely neglects such disputes is therefore ill founded.[20]

This last line of defense is, I think, only partially successful. It is certainly plausible that some appropriate notion of objective, mind-independent existence is involved in (most) ontological disputes. And it is hardly less plausible, in my view, that this notion is best elucidated in terms of the idea that statements purporting reference to entities of the problematic kind are apt to be objectively true. But the claim that the notion of objective truth thus involved in ontological questions is invariably the notion of potentially evidence-transcendent truth is surely mistaken. The truth of effectively decidable statements of elementary number theory, taken at face value, suffices for the existence of indefinitely many natural numbers; but such statements, by their very nature, cannot be candidates for evidence-transcendent truth. This suggests that there has to be some other notion of objective truth, falling short of realist truth in Dummett's sense. We shall return to this point.

Turning now to claim (2), it may be felt that even if reshaping R/AR disputes as concerned with statements (rather than entities) imports no serious loss of generality, its exclusive focus upon the character of the notion of truth having application to them is a good deal less harmless: that the result is to lose contact with what is at issue in earlier disputes about realism. Dummett replies to this charge in (1993a). Traditional opposition to realism, he observes, commonly takes the form of *reductionism*. The anti-realist about a given area – schematically, the ostensible subject-matter of A-statements – maintains that there are no distinctive A-facts: rather, A-truths can be translated or paraphrased without loss or residue into B-truths, truths of some other kind which enjoy an (at least relatively) unproblematic ontology and epistemology. Thus the behaviorist denies that there are distinctively mental facts; there are just facts about overt behavior and circumstances in which it occurs, and truths about minds translate into (complex, subjunctively conditional) truths of the latter sort. According to instrumentalists and operationists – traditional scientific anti-realists – there is no special class of truths about the unobservables of scientific theory, such talk being merely convenient shorthand for talk about observables. The fatal objection to anti-realisms of this reductionist stripe, Dummett reminds us, has been that the translation programs they enjoin simply cannot be carried through; reductive behaviorism, for example, runs aground over the holistic character of discourse about beliefs, desires, and other mental states (see Chapter 15, HOLISM, and Chapter 12, TACIT KNOWLEDGE, §2), while traditional instrumentalism fails because a suitable division cannot be sustained between observation statements and theoretical ones. But the opposing realisms, he argues, have enjoyed too easy a victory. Intuitionists in mathematics accept the irreducibility of mathematical statements, but oppose realism (as embodied in standard classical mathematics, with its reliance upon unrestricted bivalence) by insisting that their content is exhausted by an account of their justification conditions. By taking this as our model, we can see that there is space for non-reductionist anti-realist positions about the mind, or about science, or in other areas, which involve no commitment to such doom-laden translation programs. The charge of irrelevance to traditional disputes over realism is thus quite misplaced: what has been done, rather, is to disclose anti-realist options in those disputes which had not been sufficiently noticed.[21]

As against that specific charge, this is a passably effective reply. But misgivings relating to claim (2) may still be felt on a somewhat different score. Let it be granted that focus on the character of the notion of truth applicable to certain statements is well adapted to plot one kind of non-reductionist opposition to realism (and set aside, *pro tem*, the question how widely available this kind of anti-realism is): it appears, nevertheless, quite ill adapted to accommodate other, equally non-reductive forms which opposition to realism may, and in significant cases does, assume. Two such directions of anti-realist thinking, both well represented in subsequent discussion, spring readily to mind, neither of which is happily construed as occupied with the character of the notion of truth having application within the discourses they concern.

There is, first, the view – paradigmatically exemplified in the emotive theory of ethical discourse embraced by some logical positivists, and foreshadowed in the writings of Hume (cf. Hume, 1739, bk. III, pt. I. §II; Ayer, 1946, introduction, pp. 20–22, and ch. VI) – that the seemingly fact-stating, descriptive utterances characteristic of a given region of discourse are not genuine assertions at all, but are rather to be understood as expressive of feelings (whether of approval or disapproval, admiration or distaste) which we project onto the natural goings-on by presenting them in assertoric or propositional style. This projectivist species of anti-realism is to be sharply distinguished from a crude subjectivism according to which ethical utterances are sincere or insincere, true or false *reports* of morally relevant feelings. In its original and purer form, at least, it maintains not that ethical utterances fail to comply with standards of objective truth-telling, but that they are not apt for evaluation as true or false at all. While it finds its most natural, and perhaps its most plausible, application in connection with morals, and evaluative discourse in general, it admits – or is often taken to admit – of extension to other areas. Hume himself may be seen as commending a projectivist treatment of causal necessity; others, following his lead, have advocated similar treatments of other areas – for example, of modality in general (see Chapter 31, MODALITY, §§3.1 and 3.4), and even of mathematics (cf. Blackburn, 1984, pp. 210–217; 1986, passim).

There is, second, a quite different – indeed, opposed – direction of theorizing which accepts the sentences of a problematic discourse as vehicles of genuine statements, aimed at truth, but denies that they can ever attain to it on the ground that reality fails to furnish objects, properties, or states of affairs of the kinds their truth demands. Versions of this species of anti-realism – error theories, as they are often called – have been advocated in relation to moral discourse by John Mackie and to mathematics by Hartry Field; eliminativist doctrines about ordinary or 'folk-'psychological discourse are perhaps also best viewed as error-theoretical.[22] In sharp contrast with more traditional, reductionist forms of anti-realism, it is held that the statements of the discourse do indeed carry the ontological commitments their surface syntax suggests – to distinctively non-natural moral properties and states of affairs, for example, or to numbers and sets – but that, precisely because there are in reality no such things, those statements are quite generally false.

Whether either of these approaches should ultimately be reckoned the best, or even a sustainable, direction anti-realist intuitions might assume is a question to which we shall return. The present point is, quite simply, that they constitute *prima facie* playable options for opponents of realism who want no truck with orthodox reductionist strategies – naturalism in ethics or a program of reinterpreting mathematics as concerned solely with nominalistically acceptable concrete entities – but they are options which can, it seems, find no place in Dummett's configuration of R/AR disputes.[23] Their availability tells, in the first instance, against claim (2). However, since neither the error-theorist's not the expressivist's

quarrel with the realist concerns the possibility of holding statements in the disputed class to be capable of evidence-transcendent truth – or subject to bivalence – these examples tell also, albeit indirectly, against claim (3).

A more direct objection to claim (3) – or to taking endorsement of bivalence as the hallmark of realism – focuses upon the phenomenon of vagueness. On one widely accepted view, vague statements are precisely ones which lack determinate truth-values. If that is so, then Dummett's characterization would seem to leave no space for any form of realism about vague discourse (cf. Wright, 1993a, p. 4). Given the very considerable extent to which vagueness pervades our language, this would constitute a serious limitation. But it is not clear that the objection is decisive. One quite radical response to the objection would be to reject the assumption on which it proceeds, that vagueness involves lack of truth-value. Such is the burden of the epistemic conception of vagueness, which has received some ingenious and determined support.[24] In this view we hesitate or are reluctant to assert, in problematic cases, that a certain colored patch is red or that a certain man is thin, not because these statements lack determinate truth-values, but because we do not know what those truth-values are. As Dummett observes, this requires us to hold that our use of vague expressions "confers on them meanings which determine precise applications for them that we ourselves do not know."[25] Finding this supposition implausible, Dummett offers a quite different answer to the objection, contending that the realist should hold that, for every vague statement, there is a range of more precise statements exactly one of which is true and the rest false, while an anti-realist is free to deny this. His thought, it seems, is that while a realist need not endorse an unrestricted principle of bivalence, he can only allow failures where they can be put down to an eliminable lack of precision on our part: if a statement lacks truth-value, that is due not to any indeterminacy in reality but to some looseness in our description.[26] Whether this conception involves no significant departure from the idea that realism is to be characterized in terms of commitment to the possibility of evidence-transcendent truth, or whether, alternatively, unrestricted bivalence may – at least as far as the difficulty over vagueness is concerned – be retained as the mark of realism by upholding an epistemic conception, are delicate questions we shall not try to resolve here.

4 Error Theories, Projectivism, and Quasi-realism

Even if an affirmative answer to either of these questions can be sustained, there are, as remarked, lines of attack apparently open to anti-realists which seem not to fit comfortably into Dummett's general characterization of R/AR disputes, since the relevant anti-realist thesis is not that the problematic statements cannot have evidence-transcendent truth-values, but that they are either not really up for assessment as true or false at all (the expressivist/projectivist option) or invariably false (error theories). It may begin to seem that it is not just Dummett's particular focus that distorts or oversimplifies, but that any attempt to identify some one kind of thing that is at issue in all R/AR disputes is unlikely to do justice to the variety of forms opposition to realism – and, correlatively, realism itself – may take. We shall consider in the next section whether the prospects for an illuminating overview are as bleak as our discussion so far suggests. First, it will be convenient and instructive to review, if only and inevitably somewhat briefly and provisionally, the error-theoretic and expressivist options, along with some more sophisticated variants of them.

In its starkest and most uncompromising form, error-theoretic anti-realism would seem to enjoin rejecting the problematic discourse outright, as resting upon presuppositions which, if its negative ontological claims are correct, are recognizably unfulfilled. The continued practice of making moral distinctions, coupled with recognition that the world fails to provide states of affairs of the kind which that practice, properly understood, demands would amount at best to bad faith. If that is a consequence we should find it hard to swallow in the moral sphere, its analogue in the mathematical case seems, if anything, even more clearly intolerable, given the apparent indispensability of mathematics to successful theorizing about the world. For this reason, much interest and importance attaches to the possibility of mitigating the apparently disastrous consequences of pure error-theoretic anti-realism by combining it with a supplementary theory which would explain how, error notwithstanding, we may be rationally justified in continuing to practice the discourse in question. Field (cf. Field, 1980; 1989) may fairly be viewed as arguing for just such a modified error theory about mathematical discourse. Mathematical statements, taken literally and at face value, are indeed, by his nominalist lights, systematically false, simply because the world fails to contain the numbers, functions, sets, and so on required for their truth.[27] But it is, in his view, a further error to suppose that this deprives them of any respectable employment. Mathematics does not need to be true to be good. What is required – and all that is required – to justify the use of mathematical theories in everyday or scientific theoretical contexts is that such theories should be *conservative*, in the sense that relying upon them in reasoning about non-mathematical matters does not enable us to reach any non-mathematical conclusions from non-mathematical premises which are not logical consequences of those non-mathematical premises alone.[28] If this idea can be made to work, it promises at least one significant advantage over more traditional forms of nominalism, by doing away with the need for the kind of reductive translation program in which – with less-than-encouraging prospects of success – they standardly engage. Whether it *can* be made to work is too large a question for adequate treatment here, but one serious-looking problem merits brief mention. This concerns the belief in conservativeness which supplants a belief in truth as the core of this anti-realist position. The question is whether Field can give a satisfactory account of its content without destabilizing his nominalism. To be conservative, a mathematical theory must be consistent. Since a theory's consistency cannot be explicated in the usual model- or proof-theoretic terms without breaking faith with nominalism, Field must take it to consist in the possibility that its axioms are collectively true. But they are in fact false in his version of nominalism. The implausible upshot would seem to be that the existence/non-existence of numbers and such like must be, in Field's view, not merely a pure contingency, but a metaphysically brute one. Any purported explanation, in nominalistically acceptable terms, of its resolution – either way – would locate non-mathematical states of affairs which would have been otherwise, had the alleged contingency been otherwise resolved, and would thus be in tension with the conservativeness of mathematical theories. The objection, it should be stressed, is not to the notion of brute contingency as such, but to the idea that the (non-)existence of numbers and sets may be properly regarded as exemplifying it.[29]

Expressivism about a discourse avoids this particular difficulty, since it denies that its utterances are genuine statements, properly assessable as true or false. But in its pure form, it runs into others. Typically, the problematic utterances will exhibit many, if not all, of the main features – with, of course, the exception, if expressivism is right, of a capacity for truth-value – of genuine assertion. Moral and modal utterances, for example, happily

tolerate embedding under negation, within disjunctions and conditionals, and in reports of propositional attitude. They are at least – however misleadingly – *said* to be true, or false. And, most importantly, they may figure – both atomically and under such embedding – as premises or conclusions of what are, to all intents and purposes, deductively valid inferences. Since Geach (1965) first drew attention to the fact, it has been a commonplace that expressive theories encounter grave difficulty in doing justice to these indisputable aspects of use, as they must if they are to be credible. Whatever attitude or sentiment is expressed by a free-standing utterance of 'Lying is wrong,' say, those same words can no longer be held to express it when they figure as antecedent to a conditional, such as 'If lying is wrong, so is getting others to lie.' On the face of it, the antecedent position needs filling with words articulating a condition which may or may not be met, and so by words apt to express not a feeling but a truth. In addition, if 'Lying is wrong' does no more than express a feeling when uttered on its own, it is difficult to see how the ostensibly valid inference from it, together with the above conditional, can be anything other than a crude equivocation.

A sophisticated development of the expressivist/projectivist approach has been forcefully advocated by Simon Blackburn. It is a central objective of his *quasi-realism* to show that acknowledging the expressive/projective basis or origin of moral discourse – to take the case for which his view is most fully worked out – need force no admission that our tendency to talk and think *as if* moral judgments are genuine assertions, having truth-conditions, is misplaced or defective. In his words, quasi-realism seeks to show "that even on anti-realist grounds, there is nothing improper, nothing 'diseased' in projected predicates … it tries to earn, on the slender basis [i.e., of projectivist assumptions], the features of moral language (or of the other commitments to which a projective theory might apply) which tempt people to realism."[30] Earning the right to present our moral or other evaluative commitments in propositional style – as Blackburn would put it – evidently requires, *inter alia*, solving Geach's problem. Blackburn's proposal is that when we assert conditionals with evaluative components, like 'If lying is wrong, so is getting others to lie,' we are expressing complex, higher-order evaluative attitudes – in this case, of approval towards combining disapproval of lying with disapproval of getting others to lie. This, he hopes, enables us to explain what is going on when we make evaluative inferences, such as the moral *modus ponens* we have taken as example. Someone who sincerely endorses the premises approves of combining disapproval of lying with disapproval of getting others to lie, and disapproves of lying. She ought, therefore, to disapprove of getting others to lie (thereby sincerely endorsing the conclusion), since if she does not she will be involved in a kind of attitudinal inconsistency – her attitudes will clash with one another, as Blackburn puts it.[31]

This fails to do justice to the problem. Someone who declines to accept the conclusion that getting others to lie is wrong from the given premises is to be convicted of *logical* incompetence, and not a merely *moral* fault (failing to have a combination of attitudes of which one approves), as on Blackburn's account of matter.[32] There is, in any case, room for doubt whether the approach can be extended to cover the full range of utterances which are, in Blackburn's view, ripe for projectivist-cum-quasi-realist treatment. It is unclear, for example, that it can deal satisfactorily with 'mixed' conditionals and other compounds involving genuinely factual components alongside evaluative ones, such as 'If Henry said that, he ought to apologize.'[33] Again, a projectivist/quasi-realist treatment of modality has it that 'It is necessary that p' functions to express our own imaginative limitations – something

like 'inability to make anything of a possible way of thinking which denies [that p]' (cf. Blackburn, 1984, p. 217) – but there seems little prospect of dealing with iterated modalities in this style.

5 Realism and Objective Truth

Let us take stock a little. We have largely been concerned to assess the adequacy of Dummett's characterization of R/AR disputes. Our discussion suggests that whilst some such disputes are indeed to be seen, as Dummett recommends, as turning upon the tenability of a conception of truth and falsity as potentially evidence-transcendent, there are others where this is not the issue. It seems, for example, that there should be space for a position appropriately describable as realist about (even) effectively decidable mathematical statements. Realists about morals, or about modality, need not, it seems, embrace evidentially unconstrained conceptions of moral or modal fact simply by virtue of their opposition to error-theoretic and expressivist/projectivist accounts of the subject-matter. It merits emphasis that what these and other examples call in question is not, as such, the aptness of Dummett's depiction of realism as 'the belief that statements of the disputed class possess an objective truth-value, independently of our means of knowing it: they are true or false in virtue of a reality existing independently of us': this remains – at least for anyone who accepts that the issues are best seen as primarily concerning a class of problematic statements, rather than a class of problematic entities – as good a schematic characterization of the position as we might hope to give. Rather, what they tell against is the particular, and particularly exacting, interpretation Dummett imposes upon its key ingredient terms – 'objective truth-value,' 'independent of our means of knowing,' and 'independent reality.' Encashing these notions in terms of potential for evidence-transcendent truth undoubtedly hits off one very strong sense in which the states of affairs a given kind of statement purportedly represents may be held to be objective and independent of our talk and thought. But might there not be other, less demanding but still substantial, conditions whose satisfaction by (true) statements about a given subject-matter would suffice for the correctness of (a form of) realism about them? An affirmative answer would invite acceptance of one broadly negative moral: that there need be no one, unique mark of realism uniform across all R/AR disputes – no one thing that is at issue in all of them. But that need not be seen as enforcing the disappointing conclusion that we are confronted with no more than a rag-bag of disparate oppositions, with nothing but a label in common. It need not do so, at least, provided we may view the relevant conditions as reflecting features of – or constraints upon the application of – the notion of truth properly deployed in the various regions of discourse over which realists and anti-realists of one or another kind may disagree. This, in broad outline, is the overall picture recommended by Crispin Wright, of which we now provide a brief review.

In contrast with expressivists, Wright argues that anti-realists about a given discourse should acknowledge, along with their realist opponents, that its distinctive utterances are genuinely assertoric and so apt for evaluation as true or false; and that, in contrast with error theorists, there is no systematic reason why its assertions should fail to be true. As Wright recognizes, this makes urgent two questions: How can the concession that the relevant utterances are truth-apt, and that many of them are indeed true, 'avoid giving

the game to the realist straight away' (unless coupled with some form of reductionist reconstruction of those statements)? And, assuming a satisfactory answer to that question, what *is* in dispute between realists and anti-realists, if both parties agree that the problematic statements are not only truth-apt, but in many cases actually true (as they stand, without benefit of some reductive analysis in terms of statements of some other discourse)? What is left for them to disagree *about*? To answer the first question, Wright circumscribes a notion of truth – *minimal* truth, as he calls it – which is neutral between realists and their opponents. To answer the second, he identifies a number of truth-related issues over which parties who agree on the minimal-truth aptness, or minimal truth, of certain statements may yet diverge – issues where what is in question can be seen as a feature whose possession by those statements would constitute their being *substantially* true in one or another of the ways suggested by the familiar realist idioms of objective or mind-independent truth, or truth in virtue of some sort of correspondence or fit with external reality.

Minimalism

If minimal truth is to serve Wright's purposes, it must be, as he puts it, a 'metaphysically lightweight' notion, unencumbered by any of the features which import realist commitments. But it cannot, he argues, be the metaphysically *weightless* notion which a distinguished tradition initiated by Ramsey and including Wittgenstein, Ayer, and most recently Horwich (Ramsey, 1927: Wittgenstein, 1922; 1953; Ayer, 1946, pp. 78–90; Horwich, 1990) has taken truth to be. According to this conception – *deflationism* – the truth predicate stands for no real property, but is no more than a mere device of disquotation. That is, the effect of applying the truth predicate to a name of a sentence – say, one formed by enclosing the sentence in quotation marks – is to produce a sentence which says no more and no less than can be said by asserting that very sentence on its own without surrounding quotation marks. Thus on this view, the whole meaning of the truth predicate is exhausted by the Disquotation Schema:

(DS) "P" is true if and only if P

Wright argues that deflationism is unstable, because, when coupled with the seemingly undeniable assumption:

(Neg) Every statement, P, has a negation, not-P

it entails inconsistent claims concerning the relations between truth and warranted assertibility. Both are clearly norms of assertoric discourse, in the sense that in making assertions, we aim at truth, and likewise aim to make assertions we are warranted in making. Deflationism is committed, via its endorsement of (DS), to accepting the normativity of the truth predicate, in the sense that reason to think a sentence true is reason to assert or accept it. Indeed, (DS) entails that 'true' and 'warrantedly assertible' *coincide* in *normative force,* in the sense that reason to think a statement true is reason to think it warrantedly assertible, and conversely. But deflationism is also committed, by taking the content of the truth predicate to be exhausted by (DS), to holding that the truth predicate is simply a device of assertoric endorsement and hence to denying that truth is a norm of assertion distinct from being warrantedly assertible. However, it follows from (DS), together with (Neg), that truth

and warranted assertibility must be distinct norms of assertion, since the predicates expressing them can diverge in extension. For it follows from (DS) together with (Neg) that:

(1) "It is not, the case that P" is true if and only if it is not the case that P

And contraposing on (DS) itself, we have:

(2) It is not the case that P if and only if it is not the case that "P" is true

whence, by the transitivity of the biconditional:

(3) "It is not the case that P" is true if and only if it is not the case that "P" is true

But the result of replacing 'is true' by 'is warrantedly assertible' in (3) is clearly incorrect. Provided that a state of information is possible which is neutral with respect to P – that is, which fails to warrant P or its negation – the resulting biconditional fails right-to-left: it may be that neither "P" nor "It is not the case that P" is warrantedly assertible.[34]

Wright contends that the combination of coincidence in normative force with, but potential divergence in extension from warranted assertibility is not only a necessary condition for something to be a genuine truth predicate, but that it is also sufficient. This is (one way to formulate) what he understands by minimalism about truth. It is worth emphasizing that minimalism about truth is, by itself, perfectly consistent with expressivist or error-theoretic anti-realism about a discourse, since it remains, so far, open to the expressivist to deny that the discourse's utterances are genuinely assertoric, and open to the error theorist to grant their assertoric status but still deny that any of them qualify for even minimal truth. Wright does in fact reject both positions. His rejection of expressivism rests upon the further claim that we should adopt a similarly minimal conception of assertion, according to which it suffices for the sentences of a discourse to be assertoric that they exhibit the appropriate syntactical features (embedding under negation, as antecedents of conditionals, in contexts of propositional attitude reports, and so on) and are subjected to 'communally acknowledged standards of proper use' or what he often calls 'discipline.' His rejection of error theories is more qualified, and the reasons for it too subtle and complex for discussion here (see Wright, 1992, pp. 86–87).

There is one final point that needs to be made about Wright's minimalism if his positive suggestions about what is or should be at issue in R/AR disputes, to which we shall shortly turn, are not to be misunderstood. This is that the minimalist conception is not put forward as an *analysis* of truth, in direct competition with traditional 'theories of truth' like the correspondence and coherence theories (see Chapter 21, THEORIES OF TRUTH). The claim is, rather, that *any* predicate which both satisfies the Disquotation Schema and exhibits certain features – ultimately those enshrined in or derivable from the 'platitudes,' as Wright describes them, that to assert a statement is to present it as true, and that any truth-apt content has a significant negation which is likewise truth-apt – should thereby qualify as *a* truth predicate. It is therefore consistent with acknowledging that there is, or even must be, more to say about the content of any predicate endowed with those features. It is, further, consistent with a certain kind of pluralism about truth – with the idea that the more which there is to say may vary from one discourse to another. If that is so, then the possibility lies

open that, while we are entitled to claim truth for both moral judgments, say, and statements about the physical properties of things, the kind of truth we (are entitled to) claim for the former is different from the kind we (are entitled to) claim for the latter, and that they differ in ways germane to R/AR disputes.

Cruces

It is a consequence of this last point that there is nothing in Wright's minimalist conceptions of truth and assertion which excludes – and it is clear that there is nothing which requires – that the notion of truth applicable within a given discourse is an evidentially unconstrained one, of the kind to which a Dummettian realist aspires. Here, then, is one crux at which realists and anti-realists may part company, whilst agreeing that the statements in dispute are minimally truth-apt, and that many of them are true. But a great part of the interest and importance of Wright's reconfiguration of the debate lies in its purported identification of a number of other R/AR cruces where neither protagonist is, or need be, committed to the possibility of evidence-transcendent truth. We can get them into a useful perspective by beginning with a few further remarks on the character of the disagreement between the Dummettian realist and her opponent.

This can be redescribed in terms of Wright's notion of *superassertibility*. Roughly, a statement is superassertible if it is warrantedly assertible and is, as a matter of fact, destined to remain so no matter how our state of information is improved. Less roughly, "A statement is superassertible … if and only if it is, or can be, warranted and some warrant for it would survive arbitrarily close scrutiny of its pedigree and arbitrarily extensive increments to or other forms of improvement of our information."[35] This notion, and the claims Wright makes for it, demand a much fuller discussion that can be given here; for present purposes, two points are crucial. The first is that – or so, anyway, Wright argues (1992, pp. 44–70) – the predicate "is superassertible" meets the conditions which the minimalist conception holds to be necessary and sufficient for a truth predicate. Reason to think a statement superassertible is reason to think it is warrantedly assertible and conversely, so that 'superassertible' and 'warrantedly assertible' coincide in normative force; but a statement may be warrantedly assertible and yet not superassertible (increments to our information may destroy our warrant), so that the two predicates may diverge in extension. The second is that superassertibility is essentially an evidentially constrained notion: a statement cannot be superassertible unless we can be warranted in taking it to be so. In virtue of the first point, superassertibility can, under certain assumptions, provide an interpretation or model of the truth predicate applicable within a given discourse. But, by the second point, if the truth predicate for a discourse admits of potentially evidence-transcendent applications, then it possesses a feature which superassertibility necessarily lacks and so cannot be so interpreted. A Dummettian R/AR dispute is, then, a dispute concerning the capacity of superassertibility to serve as an adequate interpretation of the truth predicate for the problematic region of discourse. The Dummettian realist contends that the truth predicate has a characteristic – that of potential evidence-transcendence – going beyond anything involved in satisfaction of the minimalist platitudes, which enforces a distinction between truth and superassertibility.

In this case, the additional feature of truth for which the realist contends is one which would require us to accept not only that truth and superassertibility are distinct *notions*, but that they diverge, at least potentially, in *extension*. But could there not, Wright now asks,

be supplementary characteristics of the truth predicate for a given discourse which demand a *conceptual* distinction between truth and superassertibility without, however, entailing (potential) divergence in their *extensions*? There should be, if Wright's approach is to assuage the misgivings which – as previously suggested – should lead us to doubt the capacity of Dummett's general characterization to do justice to the variety and richness of R/AR disputes. He contends that there are (at least) three such features, each representing ways in which the notion of objectivity for statements of a given discourse might be interpreted, and so apt to form the focus of R/AR disagreement without raising questions about evidence-transcendence.

One issue is whether the discourse satisfies the *Cognitive Command* constraint, which it will do just in case it is *a priori* that differences of opinion arising within it can be satisfactorily explained only in terms of something worth describing as a cognitive shortcoming in one or other of the disagreed parties.[36] It might, to illustrate with one of Wright's own examples, seem quite obvious that talk of what's funny, or beautiful, fails this test – comic and aesthetic tastes may simply differ; there will doubtless be a causal explanation why I find Buster Keaton hilarious, or Rubens's women beautiful, while you do not – but it need not be one that finds cognitive fault in either of us. Perhaps the same goes for moral judgment, but this is evidently more arguable, and so could be what's at stake between moral realists and their opponents. Rightly or wrongly, virtually all of us will think that stock market reports, summaries of football results, and rainfall records pass the test.[37]

Another – the *Euthyphro contrast* (cf. Wright, 1992, pp. 108–139; also Wright, 1988b) – concerns whether our (cognitively) best judgments in a given area are to be regarded as tracking an independently constituted realm of facts (the realist view); or whether, rather, we should view truth for the discourse's statements as somehow determined by, or constituted out of, our best judgments (the anti-realist option). The label is intended to recall Plato's dialogue, which has Plato maintaining that pious acts are thought to be so by the gods because those acts are pious, while Euthyphro contends for the opposed view, that pious acts are so because the gods take them to be so. Realist and anti-realist may be presumed to agree that there will be a coincidence between the facts of the matter and our judgments made under optimal conditions. The issue then concerns the direction of dependence: Are such judgments true because they match up with independently constituted facts, or are those facts themselves no more than a reflection of our best judgments?

How might it be resolved? Wright's plausible suggestion – developing an idea of Mark Johnston's[38] – is, roughly, that the latter view should prevail if it is knowable *a priori* that the coincidence should hold. Thus it might with some plausibility be held that the truth of judgments about the colors of things simply consists in their being the judgments suitably endowed perceivers would make under optimal conditions, on the ground that it is guaranteed *a priori* that best-color judgments co-vary with the color facts. By contrast, it might be argued that even if our best judgments about the shapes of two- or three-dimensional things match up with the corresponding shape facts, this is a contingent and *a posteriori* matter. As Wright emphasizes, the suggested test demands much refinement if it is to be acceptable. For example, it would award the verdict too easily to the anti-realist, say about color facts, if the conditions for optimal judgment were specified merely as 'whatever conditions are needed and sufficient to ensure that our color judgments are true.' Rather, it must be possible to provide a substantial and independent characterization, reflecting the detailed epistemology of such judgments. It must also be required that the *a priori* coincidence of best judgment with the facts is not independently guaranteed, simply by our conception of the relevant facts themselves; for example, we may conceive of pain and other sensations as

being such that a sincere and unconfused subject is immune to ignorance and error in her present-tense judgments, but would not wish to say, for this reason, that the facts are constituted out of best judgments.

The third issue focuses on *Wide Cosmological Role* (cf. Wright, 1992, pp. 174–201; Divers and Miller, 1995): Do the facts which true statements of a given kind record have a role to play in explanations of further facts of other kinds, beyond facts about our beliefs and other attitudes, and can they figure in such explanations other than as objects of those attitudes? It might be contended that while moral or modal beliefs, for example, are apt to figure in explanations of our actions, desires, and beliefs, moral or modal facts themselves exert no influence on other goings-on; in contrast, facts about the primary qualities of bodies, for example, exert causal influence in the world at large. To the extent that this is so, we might think that this justifies a kind of realism about facts of the latter kind which is unwarranted in regard to the former.

These quite programmatic suggestions prompt a whole host of questions. How are the various realism-relevant conditions – satisfaction of Cognitive Command, passing the Euthyphro test, possession of Wide Cosmological Role, capacity for evidence-transcendent truth – related to one another? Is the first the least that can be required for a species of realism, and a precondition for kinds of realism marked off by the others, as Wright suggests? More generally, do these various conditions admit of a linear ordering, corresponding to more or less robust forms of realism? Is the list complete, or are there other realism-relevant conditions to be discerned? How does the classification relate to R/AR disputes about the existence of entities of problematic kinds? Is the merely minimal truth of statements of arithmetic, for instance, sufficient for the existence of numbers (Wright, 1992, pp. 28–29) or should a more substantial kind of truth be demanded? These and other questions must be left for discussion elsewhere, and have indeed already attracted a good deal of critical attention. To conclude, I shall comment briefly on just three doubts Wright's work has provoked.

While Wright's proposal clearly provides a more inclusive framework for the location and pursuit of R/AR disagreements than Dummett's appears to do, it may be held that there remain forms of opposition to realism which elude it. In particular, it has been claimed that the species of irrealism enjoined by the meaning-skeptical argument advanced by Kripke's Wittgenstein does not fit Wright's agenda, on the ground that it involves rejecting even the application of the supposedly neutral notion of minimal truth to statements about the meanings of words (cf. Edwards, 1994, pp. 63–65). Minimal truth is a prescriptive or normative notion – this is what sets it apart from a merely disquotational one – and this, so it is claimed, requires that a distinction can be drawn between future applications of words which would be correctly judged to accord our present understanding, and those which would not. But that distinction, in this view, is precisely what Kripke's Wittgenstein argues to be vacuous; so he denies that there are even minimal facts about meaning. Even if this is the right way to understand Kripke's skeptic – so that his position falls below the lower bound, as it were, which Wright thinks realists and anti-realists alike should surpass – I doubt that it amounts to a very serious criticism of his approach. Wright is not committed to claiming that *every* self-styled anti-realist will in fact acknowledge the applicability of minimal truth to problematic discourses; he will agree that expressivists about morals, for example, have denied it. It is another question whether rejection of even minimal truth leaves a defensible position. In the present case, he argues that it does not – that semantic irrealism is inherently unstable, because it inflates into a self-defeating global irrealism.[39]

Wright says that any predicate satisfying the platitudes that define minimal truth ought to be recognized as a truth predicate, adding that we should thus be "at least in principle open to the possibility of a pluralist view of truth: there may be a variety of notions … which pass the test" (Wright, 1992, p. 25). This – together with several further remarks in the same vein – might be taken to evince sympathy with a view according to which 'true' is *ambiguous*, bearing one sense in application to a discourse satisfying Cognitive Command (CC), another when the facts recorded by the discourse enjoy Wide Cosmological Role (WCR), and so on. Such an ambiguity thesis, like the somewhat parallel doctrine that 'exists' is ambiguous, bearing different senses as applied to feelings, to tables and chairs, or to numbers and sets, may be held to have little to be said for it and much against, and it may, accordingly, be thought a serious objection to Wright's position if it involves its endorsement. Sainsbury (1996; see also Pettit, 1996, and Jackson, 1994) makes this point, but suggests that there is no need for Wright to be committed to it; just as what (mis)leads philosophers into postulating an ambiguity in 'exists' can be accommodated by acknowledging instead that feelings, tables, and numbers are different kinds of entity, so, he proposes, Wright is best understood as proposing, not that 'true' is ambiguous, but that different kinds of thing are involved in the truth (uniformly understood as minimal) of statements of different types. This seems to involve saying that moral states of affairs (supposing them to be recorded by statements satisfying at most CC) are of a different kind from, say, those recorded by statements about the primary qualities of bodies (assuming these to satisfy WCR). In support of this suggestion, Sainsbury observes that 'true' does not in fact figure in Wright's formulations of CC, WCR, and others. The attractions of this view are obvious, but it is not clear that it speaks adequately to the threatened objection. Minimalism involves the Correspondence Platitude (Wright, 1992, pp. 25–27) that a statement is true if and only if it corresponds to the facts: it is thus not clear that Wright could avoid regarding 'true' as ambiguous in Sainsbury's way, since a distinction between different kinds of fact will induce, via this platitude, a distinction between kinds of truth. There is also a certain cost: Wright sees himself as preserving what he takes to be sound in Dummett's characterization of R/AR disputes – that is, the idea that they concern the character of the truth predicate applicable within a problematic discourse – whilst freeing it from the exclusive focus on matters of evidence-transcendence and bivalence. But it does not seem possible to do this without retaining the idea that what the truth of statements consists in varies across different discourses. The question is whether that idea enforces an ambiguity thesis. The analogy sometimes drawn between the assertoric use of language and games may be helpful here. Perhaps, as Wright at one point claims, we may view the minimalist platitudes as encapsulating the essential core of a single notion of truth (Wright, 1992, p. 38), which may be filled out in different ways in relation to different discourses, somewhat as what constitutes winning may vary across different games, without inducing any ambiguity in the word 'win' (cf. Wright, 1996).

A third cause for concern, discussed by Wright himself and pressed by some critics (Sainsbury, 1996), is that CC may fail to amount to a significant constraint over and above the requirements – syntax and discipline – for merely minimal truth. When Wright first formulates CC, he expresses it as a constraint upon *explanation* of disagreements within the discourse:

> A discourse exhibits Cognitive Command if and only if it is a priori that differences of opinion arising within it can be satisfactorily explained only in terms of "divergent input" … or "unsuitable conditions" … or "malfunction." (Wright, 1992, pp. 92–93)

But he quickly falls into another formulation, in terms of the idea that any disagreement must "involve something worth describing as a *cognitive shortcoming*."[40] There is, of course, no harm done by employing the emphasized words as shorthand for the longer list of specific types of failing appearing in the original formulation. But the shift from the requirement that differences of opinion "can be satisfactorily explained only in terms of" cognitive shortcoming to the requirement that such differences must "involve" such shortcoming is not harmless. It invites a charge of trivialization which Wright himself confronts in this form:

> But it *is* a priori that any difference of opinion concerning the comic, when not attributable to vagueness and so on, must involve cognitive shortcoming, since, if all else fails, ignorance or error will at least be involved *concerning the truth value of the disputed statement*. (Wright, 1992, p. 149)

The charge troubles Wright, who expends much energy and ingenuity in an effort to meet it by arguing that the trivializing move requires defense of an "intuitional epistemology" invoking a "special faculty … apt for the production of non-inferentially justified beliefs essentially involving its [the discourse's] distinctive vocabulary," but that postulation of such a faculty ought to be constrained by considerations of best explanation which are not easily, and certainly not trivially, satisfied. But Wright has – or so it seems to me – conceded more than he need have done. He could have seen off the trivializer much more swiftly, by reverting to the opening formulation of CC. Suppose you and I are disagreed on some comic matter. Let it be granted that there is error – cognitive shortcoming, even – on one side or the other. Still, we are nowhere near to a satisfactory explanation, *in terms of cognitive shortcoming*,[41] of our disagreement, if all we have is that either I have come short, cognitively speaking, in thinking that p – my shortcoming consisting in the bare fact that I think that p when not-p – or you have come short in denying that p, yours consisting in the bare fact that you think that not-p when p. Appeal to this cannot *explain* our disagreement that I think that p when, as you think, it is the case that not-p is precisely *what* we want *explained*. Doubtless there is an explanation to be had why, say, I think that p when, as you think, not-p. If and when such an explanation is located, it may or may not comply with the requirements of CC – but there is so far no ground for thinking that it will, as the would-be trivializer requires.[42]

Notes

1 In a fuller discussion of the major influences on realist and anti-realist thought over the last 20 years or so, our discussion of Dummett's work would be balanced by an equally extensive examination of that of Hilary Putnam. The hard editorial decision to exclude direct discussion of Putnam's work from the present chapter was rendered somewhat easier by the inclusion of a separate chapter devoted to one of his central lines of argument (see Chapter 27, PUTNAM'S MODEL-THEORETIC ARGUMENT AGAINST METAPHYSICAL REALISM). Useful remarks about the relations between the positions of these two major figures in the debate are to be found in Putnam's introduction to the third volume of his philosophical papers (Putnam, 1983) and in Dummett (1994).

2 As Dummett himself emphasizes, it is important to distinguish between bivalence and the (putative) logical Law of Excluded Middle, which asserts validity of the schema 'A or not-A.' It is, in his considered view, the *semantic* principle of bivalence on which R/AR disputes turn, rather than the logical Law of Excluded Middle, which may be validated in other ways – by the adoption of a

supervaluational semantics, for example – which involve, as such, no distinctively realist commitment. In earlier writings, it is the latter which is taken to be at issue; but Dummett subsequently declares this to have been a mistake, shifting attention onto bivalence (cf. Dummett, 1978, p. xxx).

3 Dummett (1963, pp. 155–156) suggests that rejection of the Law of Excluded Middle need involve no departure from realism. But his views on the matter have shifted in respects going beyond those indicated in the preceding footnote (cf. 1982, p. 265; 1993b, pp. 467–468).

4 For formulations of this argument, see especially Dummett (1969, pp. 362–363) and Wright (1993a, p. 13). See also McGinn (1980, p. 26; 1981) and Tennant (1981; 1984).

5 For formulations of the argument, see Dummett (1976, pp. 79–83; 1973b, pp. 217, 224) and Wright (1993a, pp. 16ff, 53–54). In (1973b, pp. 216–218), Dummett gives three arguments – from communication, from knowledge of meaning, and from learning. The last two of these correspond fairly closely to the acquisition and manifestation arguments as described here. An excellent discussion of these arguments is given in Prawitz (1977).

6 For the original suggestion, see Dummett (1969, p. 363); see also Wright (1993a, pp. 89–90) and McGinn (1980, p. 26).

7 For useful remarks about the difficulty of extending the truth-value link gambit to quantification over an infinite domain, see Wright (1993a, pp. 89–90).

8 Cf. McDowell (1978, pp. 132–133); see also Wright (1993a, pp. 90–91).

9 Cf. McDowell (1978, pp. 135–136), McGinn (1980, p. 27), and Wright (1993a, essay 3, especially pp. 95 ff.).

10 A further difficulty concerns the appeal to the distinction between chronically and merely contingently evidence-transcendent truth. Wright (1993a, p. 14) gives a snappy argument to dispel the comfortable appearance that the former category is populated only by a handful of old chestnuts like those cited as examples. Let P be any statement that is contingently undetectably true. Then the statement that it is so will itself be not only true, but *chronically* undetectably true.

11 For discussion of this issue, see Dummett (1975) and Wright (1982).

12 Cf. Dummett (1976, pp. 98–101). Dummett objects that the suggestion 'fails to answer the question how we come to be able to assign to our sentences a meaning which is dependent upon a use to which we are unable to put them.' McGinn (1980, pp. 27–28), apparently taking himself to be rehearsing Dummett's objection, claims that the difficulty lies not in envisaging the required extension of our capacities, but in seeing how they might be manifested. This would make the acquisition challenge dependent on that based on manifestation. If I am right, the former challenge can be upheld without falling back on the manifestation argument, by appealing instead to the essentially normative character of meaning. Wright (1993a, pp. 23–26) develops an independent argument from normativity against semantic realism. Although McGinn agrees that none of the responses discussed thus far is effective against the acquisition challenge, he rejects it on the ground that it relies on an unacceptable reductionist assumption that 'no conception can enter into understanding a language that is not induced directly by sensorily presented conditions; any going beyond the observational must be impossible or arbitrary' (1980, pp. 28–29). I cannot discuss this objection fully here, but I do not think it can be right – McGinn gratuitously equates what can be recognized with what can be observationally verified, thereby rendering it utterly mysterious how it is that the anti-realist could possibly regard decidable arithmetic statements as unproblematic.

13 Cf. Currie and Eggenburger (1983, p. 271); Scruton (1976); see also Devitt (1983; 1984, ch. 12) for suggestions of the first line of response, and McGinn (1980, p. 30) for the second.

14 That is, beliefs having realist truth-conditions, as opposed to beliefs in the correctness of realism. The anti-realist will hardly deny that people may manifest realist beliefs in the latter sense.

15 Cf. Wright (1993a, p. 56) for a fuller statement of the difficulty. Among other attempts to meet the manifestation challenge by locating a distinctive explanatory advantage in the hypothesis of realist truth-conditions, perhaps the most impressive and rigorously developed is to be found in work by Christopher Peacocke. Regrettably, space does not permit discussion of it here. See

especially Peacocke (1986, chs 2 and 3; 1987; 1988; 1992). Wright (1993b) criticizes some of Peacocke's specific proposals.

16 It is not entirely uncontroversial that an anti-realist account of meaning must be revisionary of our inferential practice. Dummett has always argued that it would be (cf. also Tennant, 1987) but Wright (1981) defends the opposed view. See also his (1986a), which responds to Rasmussen and Ravnkilde (1982). Wright's considered view is that an anti-realist meaning theory will enforce revision (cf. 1992, ch. 2). In effect, there is a dilemma here for the realist who would appeal to actual inferential practice to meet the manifestation challenge: *either* semantic anti-realism must be revisionary of such practice, *or* it need not be; if so, then appeal to the practice begs the question by assuming that it is beyond criticism, as out of line with the kind of meaning we have assigned to our statements; if not, then the appeal falls flat, since the practice is not distinctively realist after all.

17 This criticism assumes that Strawson is seeking to make out an operational difference between realist and anti-realist practice. But it is possible that he has in mind a somewhat different, and potentially stronger, line of argument according to which, whilst nothing in our linguistic practice as such marks it out as realist, there are theoretical considerations which constrain us to view it as informed by realist conceptions. This line of thought is pursued in Edgington (1985) and Campbell (1994).

18 Among important recent work which it has not been possible to discuss here, I should mention Blackburn (1989) and Wright's reply (1989b). A sophisticated attempt to show that acceptance of the manifestation requirement, properly understood, is not inconsistent with the assignment of realist truth-conditions is to be found in Peacocke (1986).

19 Dummett (1993b, p. 465). This particularly useful paper summarizes, defends and in places qualifies the general approach first adopted in Dummett (1963) and developed in several papers over the intervening three decades.

20 The charge that Dummett mislocates 'the realism issue' is pressed by Devitt (1983; 1984, ch. 12). An excellent discussion of the charge is given in Taylor (1987).

21 For this line of reply, see Dummett (1993b, pp. 468–471). For extensive discussion of the contrast between reductionist and non-reductionist forms of anti-realism, and detailed argument for the claim that the latter affords the basis of a sustainable anti-realist challenge in areas besides mathematics, see Dummett (1963, pp. 156–165; 1982, especially pp. 239–263).

22 Mackie (1977, ch. 1); Field (1980, pp. 1–16; 1989, essays 1 and 2); Churchland (1979); Stich (1983); the special issue of *Mind & Language* 8(2), 1993, devoted to eliminativism contains several papers relevant to error-theoretical treatments of psychological discourse.

23 Dummett (1993b) draws a distinction between what he terms 'objectivist' and 'subjectivist' attitudes towards a class of 'apparent assertibles.' A subjectivist about moral utterances takes an expressivist view of them, contending that they serve to voice attitudes or feelings, rather than to make genuine statements. In contrast with this, Dummett says, he was all along concerned with R/AR disputes between parties both of which took an objectivist view of statements in the problematic class, adding that "the dispute between the subjectivist and the 'moral realist' is not one of those to which my comparative method was meant to apply: the issues in that dispute are different and prior to it" (Dummett, 1993b, p. 467). Doubtless Dummett is quite right that a significant disagreement about what notion of truth – one that is evidentially constrained or one that is not – has application within the problematic class will take place against the shared assumption that those statements are indeed truth-apt. The fact remains that subjectivism, in Dummett's sense, is one form which opposition to realism may assume, but one which his preferred characterization of R/AR disputes simply passes by. Indeed, it is hard not to read Dummett's remark as implicitly conceding as much.

24 Cf. Sorensen (1988, pp. 199–253; 1995); Williamson (1992; 1994a; 1994b); Cargile (1969; 1979, §36); R. Campbell (1974); and see Chapter 28, SORITES. The epistemicist conception is criticized in Hyde (1995) and also in Wright (1995), to which Sorensen (1995) replies.

25 Cf. Dummett (1993b, p. 468). Indeed, on what may be the most defensible version of the epistemicist view – see Williamson (1992) – it is not merely that we *do not* know the truth-values of vague statements – we *cannot* know them.

26 He writes: "An anti-realist may … [hold] that reality itself may be vague. Whereas, for the realist, vagueness inheres only in our forms of description" Dummett (1993b, p. 468). For a searching assessment of attempts to make the contrast in this way, see Sainsbury (1995).

27 More accurately, mathematical statements are never non-vacuously true – for whilst those which carry categorical existential commitments, like 'There exist prime numbers greater than 10^{17},' will be false, general laws like 'a + b = b + a' will, if construed as universally quantified material conditionals (e.g., "For all a, b: if a and b are numbers, then a + b = b + a"), be true, but merely vacuously, precisely because no objects satisfy their main antecedents.

28 A closely related anti-realist position in philosophy of science is van Fraassen's constructive empiricism, according to which good theoretical science aims, not at correct description of unobservable realities, but at empirical adequacy – that is, roughly, at maximizing derivability of correct observationally checkable conclusions from observationally verifiable premises. See van Fraassen (1980, ch. 1).

29 This necessarily simplified formulation of the objection corresponds closely to that given in Hale (1987, pp. 106–115). For more careful presentations, see Hale and Wright (1992; 1994). Field (1989, pp. 43–45) attempts to defuse the objection, and (1993) more fully, to which the last-cited paper by Hale and Wright replies.

30 Blackburn (1984, p. 171). Blackburn (1984, ch. 6) and several of the essays in his (1993) develop his program.

31 For a more detailed explanation, together with a sketch of what Blackburn takes to be the underlying logical form of expressive/evaluative compounds, see his (1984, pp. 189–196).

32 Cf. Wright (1988a, p. 33) and Hale (1992). Blackburn (1988) makes a significantly different attempt to preserve a projectivist construal of moral utterances. This later theory cannot be discussed here. It is criticized in detail in Hale (1992). See also Gibbard (1990) and Zangwill (1992).

33 Should this be construed as expressing disapproval of Henry's saying whatever it was without apologizing? Or as expressing approval for combining the belief that Henry said whatever it was with approval for his apologizing? The former seems to lose the distinction between the case where the speaker believes that Henry spoke offensively and that where she wants to leave that question open. The latter looks to run into trouble explaining why we don't assert conditionals with evaluative antecedents and factual consequents, like 'If Henry ought to apologize, he said that.' Both approaches appear committed to locating a hitherto unnoticed ambiguity in the conditional construction.

34 As Wright himself points out, Hilary Putnam's suggested equation of truth with warranted assertibility under ideal epistemic circumstances (cf. his 1981, p. 55) encounters a similar difficulty. But the issue is delicate – see Wright (1992, pp. 37–42).

35 Wright (1992, p. 48). The notion made its first appearance in his paper "Can a Davidsonian meaning-theory be construed in terms of assertibility?" Essay 14 in Wright (1993a, cf. esp. pp. 411–418).

36 Cf. Wright (1992, chs 2 and 3). A fuller specification of the constraint is given on pp. 92–93, where the notion of cognitive shortcoming is fleshed out – the disputants are not to be "working on the basis of different information (and hence guilty of ignorance or error …), or 'unsuitable conditions' (resulting in inattention or distraction and so in inferential error, or oversight of data and so on), or 'malfunction' (for example, prejudicial assessment of data, upwards or downwards, or dogma, or failings in other categories …)." Clearly this does not purport to be a finished list. Earlier, related formulations appear in Wright (1980; see pp. 448–449; 1986b; 1989a).

37 It merits emphasis – since statements from a discourse apt for merely minimal truth have to be 'disciplined' (i.e., subject to standards of correct assertion) – that Cognitive Command (CC) is a global constraint. *Any* disagreement over one of its statements must be traceable to cognitive

shortcoming, if a discourse is to satisfy CC; whereas while particular disagreements within a merely minimally truth-apt discourse may be rationally resolvable, cognitively blameless disagreement is not ruled out *a priori*. CC – or so Wright intends – is to take up the slack left by minimal truth-aptness.

38 The source was unpublished material. Johnston (1992, esp. appendix 3) gives an impression of his later views on the matter.

39 See Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING, §3, and further references given there.

40 Wright (1992, p. 93); cf. his reformulation of CC at p. 144.

41 There will, doubtless, be a causal explanation of some sort to be found, but that is beside the point.

42 Two caveats: (a) this suggestion assumes that Wright's later formulations of CC bring no advantage that is lost by reverting to the earlier ones; (b) there may be other ways to press the trivialization threat (cf. Sainsbury, 1996, and Williamson, 1994a) which cannot be defused by the simple move proposed here, and which call for a fuller discussion than space permits.

Thanks to Jim Edwards and Crispin Wright for very helpful comments.

Postscript

BERNHARD WEISS

Bob Hale's chapter introduces one of Crispin Wright's realism-relevant cruces, the *Cognitive Command* constraint, as follows: a discourse will satisfy the constraint "just in case it is *a priori* that differences of opinion arising within it can be satisfactorily explained only in terms of something worth describing as a cognitive shortcoming in one or other of the disagreed parties" (this chapter, §5). Thus when a discourse fails the constraint it admits of disagreements in which the parties may be guilty of no cognitive shortcoming. Following recent literature let's call such disagreements 'faultless.'

Many writers argue that the notion of a faultless disagreement makes no sense; anything worth describing as a disagreement, they contend, must involve fault. Disputes, such as those in matters of taste or comic appreciation, are not disagreements, but simple divergences (see for instance, Boghossian, 2006). How the situation should be characterized largely depends on how we conceive of disagreement (see below). Others claim that the mere admission of minimal truth to a discourse suffices to establish that there is a mistake by one or other party; so all minimally truth-apt discourses would satisfy the constraint. Thus Wright's view would be incoherent because it requires us both to allow minimal truth to operate and to see it as a further and non-trivial question whether the discourse satisfies the Cognitive

Command constraint. Here's a version of the trivializing argument. Let's say that Tom and Dick differ over some matter apt for minimal truth. So Tom believes that P; and Dick believes that not-P. If Tom's belief is true then Dick believes something false. In which case Dick will have made a mistake, and will be at fault. So, assuming that no one has made a mistake, we must conclude that Tom's belief is not true. But then Tom has made a mistake, and is at fault, again contradicting the assumption that no one has made a mistake. But, since the contradiction has been derived from that assumption alone, we need to reject it: someone has made a mistake. Minimal truth precludes the possibility of appropriately faultless disagreement.

Some have questioned the framing of the constraint in terms of the notion of a *cognitive* shortcoming. If thinking about the nature of realism involves characterizing those areas in which our judgments arise (or ought to arise) from epistemic engagement with objective fact, then we are in search of a characterization of distinctively cognitive engagement. So we seem to have presupposed just what needs clarification. Wright (2003, essays 4 and 5) tries to finesse this point by arguing that any theorist claiming the presence of a cognitive shortcoming will then need to provide an epistemology to substantiate that claim. So the constraint works by imposing a distinctive obligation on the realist, distinguishing her from her anti-realist opponent. This line of thought helps somewhat with the trivializing maneuver because it is now possible to argue that anyone who accepts the trivializing argument must provide an epistemology for the relevant class of claims. And, where the judgments made are not inferred from others, this will involve a *sui generis* epistemology, for example, postulating an ability to intuit the fact of the comic matter. But, despite this, the argument still appears troubling because it seems independently plausible that to believe an untruth is to make a mistake. Thus, even if we can't give an epistemology which explains the source of the mistake, we are committed to there being one. Put differently, if the advocate of a discourse's sustaining Cognitive Command is committed, problematically, to an intuitional epistemology for it, then the argument seems to show that an advocate of minimal truth is likewise committed.

In order to make progress, the proponent of Cognitive Command needs to find a way to allow that neither Tom nor Dick is making a mistake, though they have contradictory views. One might relativize truth to something like a standard of taste. The trivializing argument then breaks down, since we can allow that Tom's belief is true relative to *his* standard of taste and Dick's belief is true relative to *his* standard of taste. So neither party need have made a mistake, where making a mistake is believing something false from the perspective of one's own standards. Relative truth has been fruitfully discussed in recent literature; itself provides a way of opposing realism; and might provide a way, not merely of explaining the possibility of faultless disagreement, but of cashing out notions of representation that Cognitive Command had aimed at. Thus we might say that a discourse fails to be fully representational, not if it fails the Cognitive Command constraint, but if it admits of a relativized notion of truth.

Relativizing Truth

Let's be clear: our focus is not relative truth as globally applicable but the idea that local regions of discourse may demand a relative notion of truth. We shall try to be a little more precise about relative truth and then we'll question whether it allows for a conception of faultless disagreement.

Familiarly, some features of language – such as indexicals and demonstratives – entail that the content of utterances of the same sentence may vary from context to context. To use Kaplan's (1989) terminology, the sentence has a fixed character, which can be employed in different contexts to express different contents. But applying the model here doesn't enable one to capture the phenomenon of faultless disagreement, since, though it allows for faultlessness, it expunges disagreement. Tom's utterance of 'Parsnips are delicious' would have a content roughly equivalent to his, Tom's, utterance of 'I find eating parsnips pleasurable'; and Dick's utterance of 'Parsnips are not delicious' equivalent to his, Dick's, utterance of 'I do not find eating parsnips pleasurable.' Of course, there is nothing contradictory about these utterances. Though Tom and Dick react differently to the experience of eating parsnips, this, in itself, doesn't constitute a disagreement. To cater for disagreement the tactic is, not to relativize content, but to relativize truth.[1] We can evaluate a content for truth at different circumstances, most obviously at different possible worlds. So the content expressed by my current utterance of 'I am hungry' is true in this world where I skipped breakfast, but is false in a world where I got up slightly earlier and ate a decent breakfast. The thought underlying relativism about truth is that we may be able to find other circumstances of evaluation – such as standards of taste – which allow the *same* content to have different truth-values at different such circumstances. So Tom's utterance is true at his circumstance of evaluation, since parsnips are delicious relative to his standard of taste, but is false at Dick's.

There are serious difficulties in making sense of a circumstance of evaluation and in explaining how a content is determined as true or false by a given circumstance of evaluation (see Boghossian, 2006). Wright (2006) suggests that superassertibility may provide a suitable model of truth here: we can imagine that 'Parsnips are delicious' is assertible (on the basis of Tom's subjective reaction) for Tom and is enduringly so, but 'Parsnips are not delicious' is assertible (on the basis of Dick's subjective reaction) for Dick and is enduringly so. But let us rather question whether the model provides a good way of understanding faultless disagreement.

It seems clear that we can make sense of the absence of fault – neither Tom nor Dick is at fault from *his* perspective – but do we have a clear disagreement?[2] We need to be clearer about what it is to disagree. MacFarlane plausibly writes:

> [T]wo parties disagree (as assessed from [circumstance] C) if … (a) there is a [content] that one party accepts and the other rejects, and (b) the acceptance and rejection *cannot* both be accurate (as assessed from C). (MacFarlane, 2007, p. 26)

Then we have an account of accuracy:

> An acceptance (rejection) of a content, p, is accurate as assessed from a circumstance C iff p is true (false) at the circumstance C.

When we put this together with the account of disagreement we get this simplification, since the same content cannot be both true and false at a single circumstance of evaluation:

> Two parties *disagree* just in case there is a content that one party accepts and the other rejects.

Take it that:

If an acceptance (rejection) is accurate then it is faultless.

And now it is possible that Tom can accurately accept the content *parsnips are delicious* and Dick can accurately reject that content. So they disagree but do so faultlessly.

Fine; but what sense do we have that the acceptance and rejection are in some kind of tension, a tension which betokens disagreement? There seem to be two possible sources of the tension. So, first, we might say that there is a tension between the two acts because the success of the one precludes the success of the other. But, second, we might say that there is a tension between the two acts because there is a conflict between fulfilling their respective commitments.

To be sure, there is no perspective, no circumstance of evaluation, in which what both Tom and Dick do are regarded as successful. So, no matter who Harry is, Harry will not be able rationally to accept that each act was successful. But why should either Tom or Dick care about success from Harry's perspective? Given that the *agent's* aims will determine success or failure of an act and that these are circumscribed by her perspective, no other perspective can have a bearing on the success of her act. The notion of aim is too agent-centered to do the right work, at least, in a relativistic setting.[3] Each speaker might well achieve her aim (and will do so if the disagreement is faultless).

So, from the perspective of the speaker, only her own circumstance of assessment is relevant to her aims. MacFarlane instead locates the relevance of *others*' assessments in the (Brandomian; see Brandom, 1994; 2001) business of giving and asking for reasons, of challenging assertions and responding to challenges. He takes it to be a brute fact about our practice that:

- one is entitled to challenge an assertion when one has good grounds for thinking that the assertion was not accurate (relative to the context of assessment one occupies in issuing the challenge), and
- a successful response to such a challenge consists in a demonstration that the assertion was, in fact, accurate (relative to the context of assessment one occupies in giving the response). (MacFarlane, 2007, p. 28)

So MacFarlane's strategy is to bring in circumstances of evaluation other than that of the speaker by focusing on the normative status of her assertion and on the commitments she incurs in asserting, namely, commitments to respond to legitimate challenges.

What drives the whole process is the insertion of acts of assertion in the business of giving and asking for reasons. But, when Dick challenges Tom, his challenge is bound to seem misplaced to Tom – because it emerges from an alien standard of taste – and when Tom responds his response is bound to seem misplaced – for analogous reasons. As MacFarlane admits, the parties may go on fruitlessly exchanging reasons until they get bored of the carry-on and move on.[4] Of course, in any exchange of reasons, parties may at times talk past one another, but when they do so we generally think of them as having failed in some manner. However, on the proffered account, this is just what we should expect: it seems an inevitable feature of the *practice* for which *practitioners* can in no way be blamed. Let us leave the debate at this inconclusive juncture; we still await a convincing conception of disagreement which allows for faultlessness. I want to close by considering a novel framework for realism/anti-realism debates.

Realism and Grounds

As Bob Hale outlines, Dummett understood disputes about realism as essentially semantic in nature and championed this conception as providing us with a neutral arena in which to prosecute the metaphysical debate. So the philosophy of language colonizes (an area of) metaphysics; but Kit Fine (2001) has recently put forward a view which resists these imperial ambitions, yet promises also to find a neutral way to negotiate the issue.

Fine thinks that realism is a view about the constitution of reality.[5] A primary notion implicated in the view is that of a ground. True propositions Q, R, and S ground another true proposition P just when it being that case that P consists in its being the case that Q, R, and S. As an example, Fine presents us with its being the case that Britain and Germany were at war in 1940 consists in…. (where the ellipsis is filled in with an exhaustive description of the relevant warlike activities of all relevant individuals).

So propositions Q, R, and S *actually* provide a ground for P, given the way the world is. Had things gone differently, P might have been grounded in a quite different set of propositions. So the grounding relation needs to be distinguished from a reduction of P to another set of propositions; in general, a reductive thesis holds that the meaning of the reduced propositions is given by the logical complex of reducing propositions. No such claim is involved in the grounding relation.

Fine's aim is to understand factuality in terms of grounding. He shows how a difference of view about the factuality of a proposition will play itself out in terms of facts about grounding, taken to be neutral in relation to the dispute. Although the details are complex, the basic idea is simple enough, though ingenious.[6] Dispute about the factuality of a proposition is pursued from that proposition to its grounds and ultimately to a dispute about the factuality of a constituent of a basic proposition. So, for instance, we might locate a dispute about the factuality of a moral proposition such as 'Harming dogs is wrong,' in the factuality of a constituent of this proposition, namely the property of being morally wrong ('wrongness' for short). So far there's no hint of a neutral forum for the debate, but Fine cleverly finds one by transferring the question about the factuality of wrongness into a question about the grounding of a proposition. The trick here is to note that wrongness will be a constituent of propositions which *both* sides agree are *factual*, for instance, the proposition that 'Harry believes that harming dogs is wrong' or that '"Wrong" refers to wrongness.' And now the question is: What grounds the truth of this factual proposition? The disputants must disagree, since they agree that a factual proposition cannot have grounds which essentially include a non-factual constituent.[7] So the factualist about morals can allow wrongness to be a constituent in the grounds of relevant factual propositions, the anti-factualist cannot. Thus their dispute about factuality must become a dispute about grounds, which, recall, Fine thinks is relatively uncontroversial.

We cannot examine the view properly here, but a concern is that the view begs metaphysical questions by helping itself to views about the nature and constitution of propositions.[8] Moreover, if, as some think, propositions need to be understood in terms of their linguistic expression, it is not clear that the proposal avoids thinking of realism in terms of the semantic relations between classes of statements.

The Variety of Conceptions of Realism

Dummett[9] sees realism from the start as a view about the relation of the world to our portrayal of it.[10] Fine demurs, seeing realism as a view about the constitution of reality. Though we might push these conceptions towards points of contact, would it impugn philosophical preoccupation with realism if we allow that there is a marked divergence here?[11] Not obviously so. The very same sense of a complex of issues – rather than a single crux – inhabits Dummett's later writings on the subject.[12] There he works still with the idea that the relevant notion of truth is crucial – because of its links with that of objectivity – and argues that theses about reference and about reduction are frequently important because of their impact on the notion of truth. However, he allows that these are pertinent beyond those consequences; evidently he does so, because he is concerned also to think about realism in terms of the constitution of the world.[13] Why expect that a complex of seemingly diverse debates should be capable of being distilled to a single underlying issue and otherwise rejected as simply confused?

Notes

1 The strategy is employed by Kölbel (2002; 2003), Lasersohn (2005), MacFarlane (2007; 2014), and Wright (2006).
2 It is worth noting that Wright gives up on talk about disagreement and talks instead of the parties as having contradictory beliefs. Rosenkranz (2008) also pushes a similar complaint.
3 As MacFarlane himself notes (2007, p. 27) as does Evans (1985).
4 Marques (2014) uses observations of this sort to argue that MacFarlane fails to ground a genuine notion of assertion.
5 A view shared with, among others, Devitt (see his 1991).
6 My presentation inevitably ignores many subtleties.
7 This is a simplification of Fine's principle (f): "any true imperfectly factual proposition [one including a non-factual constituent] has a perfectly factual ground [i.e., a ground including only factual constituents]" (2001, p. 18).
8 See Horwich (2010, essay 13) for a critique.
9 For recent debate of Dummett's views see Dummett (2004; 2006), Putnam (2010), and Dolev (2000).
10 Some don't see mind-independence in semantic terms; Khlentzos argues that even so, it should be seen as having semantic consequences (see his 2004, pp. 33–35).
11 As one recent commentator, Horwich (2006), claims.
12 See his paper "Realism" (1982) reprinted in his 1993.
13 Kitcher (2001) also sees these debates as having a dual character: (i) reduction of statements to a privileged class of statements; (ii) the applicability of correspondence truth to those statements. But he thinks anti-realists in each dispute are guilty of a single error.

Theories of Truth

RALPH C. S. WALKER

1 Introduction: Problems with Correspondence

There are often said to be five main "theories of truth": the correspondence theory, the coherence theory, and the pragmatic, redundancy, and semantic theories. It is not really clear how far these theories are in competition with one another, for it is not clear how far they address the same question. However, they are all concerned with truth and falsity as properties of what people say or think. There are other uses of "truth" and "true," as when we speak of a true friend, but these are set aside, perhaps as derivative, at any rate as different.

Various views are held about how the content of what we say or think should be specified, and thus about what the bearers of truth are. Some people would specify it in terms of sentences, pieces of language, as uttered by a particular speaker at a particular time; for them, these would be the bearers of truth. Others would say that truth-bearers are statements or propositions, where these are thought of as what meaningful utterances of sentences express. Others again would say that they are judgments, mental contents which may or may not be expressible in language but which nevertheless embody thoughts. For many purposes this issue is a red herring; where it is not, I shall call attention to the fact. But in general, theories of truth have been concerned with a relation between the world and what we say or think about it; and much of the time it matters little whether the content of our thought is taken to be a judgment, a proposition, or just a sentence.

The correspondence theory of truth holds that for a judgment (or, say, a proposition) to be true is for it to correspond with the facts. In a sense this is obvious, but taken in that way the theory is unilluminating. Colloquially, "corresponds with the facts" can function as a long-winded way of saying "is true": so understood, the alleged theory becomes an empty tautology. To have content, it must at least claim that for a judgment to be true is for it to stand in a certain relationship ("correspondence") with something independent of that judgment, a fact or state of affairs in the world. Since this still seems hard to disagree with,

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

it is natural to think that a correspondence theory fully worthy of the name must go on to say something substantial about the relationship of correspondence, and also about the facts or states of affairs with which true judgments correspond. The paradigm of such a theory is Wittgenstein's in the *Tractatus*, and we shall return to it. It is not, however, clear that anything can be said about the correspondence relation, except that it is the relation in which a proposition stands to the world when it is true; nor is it clear that the relevant facts, or states of affairs, can be specified except as those which make a particular proposition true. These are standard objections to the correspondence theory. That they are plausible objections can be borne out by the odd position one can get into if one takes the correspondence theory, in this strong form, really seriously. Russell held such a view, in his Logical Atomist phase, and became much exercised over whether the world contains negative facts or not (Russell, 1956, p. 211). Is "The Queen is not bald" true in virtue of its correspondence with a special negative fact, or just in virtue of its lack of correspondence with any positive facts? For someone who held the correspondence theory in its strong form this would seem a real issue; others might think the theory had taken us off the rails.

2 The Coherence Theory and the Pragmatic Theory

The coherence theory of truth equates the truth of a judgment with its coherence with other beliefs. Different versions of the theory give different accounts of coherence, but in all its forms the point is to exhibit truth as an internal relation between beliefs. The theory holds that the truth, or falsity, of a belief can be determined by discovering whether or not it meets the appropriate test of coherence. In all its forms, again, the coherence in question is coherence with other things that are believed or subscribed to, or at least with other things that would be believed or subscribed to under specifiably ideal circumstances. The coherence theory is therefore not committed to the absurdity of accepting as true an arbitrary set of propositions which happens to be internally coherent. Whatever the standards of coherence may be, it seems likely that alternative sets of propositions will meet them: as Russell (1906–1907) pointed out, although the highly respectable Bishop Stubbs died in his bed, the proposition "Bishop Stubbs was hanged for murder" can readily be conjoined with a whole group of others to form a set which passes any plausible coherence test; and indeed, the same can be said of the propositions that make up any good work of realistic fiction. Russell thought this an objection to the coherence theory, but it is not, for the coherence theory is concerned with coherence not amongst arbitrary propositions, but amongst beliefs.

As to whose beliefs, different versions of the theory again hold different things. Some would equate them with the beliefs held by our society, or, perhaps, the beliefs held by humankind in general. Since the beliefs even of a single person will include some that are inconsistent, what is required cannot be coherence with all the beliefs in question but with a majority, or with a majority weighted in some way, perhaps in terms of how deeply they are held. Even so, we normally think that many of our most deeply held beliefs may turn out false, as beliefs in demons have done; and we also think that many of the truths to be discovered in years to come could not be shown to be true simply by their coherence with our present beliefs. Hence some coherence theorists regard truth not as coherence with what we actually do believe, but with what we would believe under idealized circumstances – perhaps, as Peirce (1878) suggested, at the end of all human enquiry. Anyone taking this line must have in mind some non-trivial specification of what these circumstances would be;

if they were just "the circumstances under which we would believe the truth" the theory would collapse into vacuity. Other coherence theorists, perhaps more prominent in the past than at present, have met the same difficulties by a different move, regarding truth as coherence not with human beliefs, actual or potential, but with the beliefs of God or of an Absolute Mind.

Coherence theorists differ, again, over how widely they extend their equation of truth with coherence. Some make it cover truth of all kinds; theirs could be called pure coherence theories of truth. Others extend it more narrowly, to cover only truth of a particular kind – moral truth, perhaps, or the truth of theoretical statements in science. Perhaps the commonest position is intermediate between these, and equates truth quite generally with coherence amongst beliefs, except for recognizing a special place for sense-experience. A plausible reading of Kant ascribes such a coherence theory to him, so far as the world of appearances is concerned. The coherence that is equated with truth is, then, a coherence not just amongst beliefs, but also with the deliverances of sense-experience, or, as Kant (1781–1787, A218/B266) puts it, "with the material conditions of experience, that is, with sensation." On such a view, certain beliefs will be directly supported by sense-experience, and the truth or falsity of these will be a matter of how well they fit with the experience. There will be others whose relation to sense-experience is less direct, and whose truth is a matter of coherence within the system of beliefs, including, of course, those beliefs directly related to experience. A pure coherence theory, in contrast, would say that even for those beliefs that seem most immediately experiential – "I seem to see something blue" – truth is a matter of coherence, coherence presumably with other beliefs that the subject has or others have at the same or later times (such as the belief that there was an ink bottle there, that people's impressions of their own experience are usually reliable, and so on).

The pragmatic theory of truth is akin to a coherence theory of this Kantian kind. It holds that the truth of a belief is a matter of whether it "works," that is, whether acting upon it pays off. Acting on it pays off just in case the experiences we have are those the belief led us to expect. Thus the pragmatic theory also makes truth a matter of coherence, but coherence with future experience (Peirce, 1878; James, 1907; Dewey, 1938; and cf. Misak, 1991). The Kantian theory takes this view of one class of beliefs, except that it does not give special weight to future experience over experience past or present. Pragmatists have often moved towards mixed theories of the Kantian type, both by giving equal weight to experience at any time, and by allowing that not all beliefs have their truth-values determined by experience directly: for some, truth is a matter of coherence amongst beliefs. Quine's position is a variant of this (Quine, 1969). For him there is a difference between the two types of belief, but one of degree only. Whether the resulting theory should be called a coherence theory or a pragmatic theory seems arbitrary.

3 Coherence and Correspondence

The correspondence theory, the coherence theory, and the pragmatic theory are often presented as alternatives only one of which can be true. We have seen something of how the coherence theory and the pragmatic theory relate; but there is no reason why a coherence theorist, or a pragmatist, should not accept the correspondence theory in any of the forms so far described. No sensible coherence theorist will deny that truths correspond with the facts, in that sense of "correspond with the facts" in which it is a synonym for "are true."

No coherence theorist need deny the uncontentious claim that for a judgment to be true is for it to stand in a certain relationship, which can be called correspondence, with some state of affairs in the world. As to the more disputable form of correspondence theory, which attempts to elucidate the relationship by saying something substantive and illuminating about the relation of correspondence and about facts or states of affairs, there is no reason why a coherence theorist should not subscribe to that as well – unless, of course, there are considerations against such a theory which render it untenable for anyone.

Why, then, are the coherence and correspondence theories taken to be incompatible? For that we need more precision about what the coherence theory claims. So far I have been describing coherence theorists as "equating" truth with coherence; but that is vague. The coherence theory of truth is the theory that truth is *constituted by* coherence amongst beliefs; likewise, the pragmatic theory of truth is the theory that truth is *constituted by* conformity to (usually future) experience. These theories seek to tell us what the truth of a judgment consists in, or, in other words, to exhibit the essential nature of truth. Neither theory is merely asserting a biconditional, nor even a necessary biconditional. It is uncontroversial that we use coherence amongst beliefs as a test of truth, and that we use conformity to experience in the same way. Without subscribing to either theory of truth, someone might well hold that a belief is true if and only if it passes one or other of these tests. We normally suppose that on the whole our beliefs reflect reality, and that those are true which cohere with experience and with the web of our other beliefs. Even if one believed that the biconditional held necessarily, one might still not be either a pragmatist or a coherence theorist of truth. One might, perhaps, hold that reality was itself coherent as a matter of metaphysical necessity, and that as a matter of the same necessity our beliefs about it are, on the whole, largely true. Something like this was the view of Bradley. Bradley is often said to have held a coherence theory of truth; but that is a mistake, and the mistake lies in the failure to see the difference between a theory that says truth consists in coherence, and one which only says that, of necessity, propositions are true if and only if they meet the coherence test. For Bradley the truth of a judgment consists in its matching reality, though because of the nature of reality a judgment can be true necessarily if and only if it satisfies the requirements of coherence (Bradley, 1893, chs 13–15 and 24). For the coherence theory of truth, on the other hand, it is in the satisfaction of those requirements that the truth of a judgment consists.

A claim about what truth consists in is not usually intended to be analytic. It is not supposed to be a claim about concepts, but rather to be about what that property, truth, really is. In this it resembles the claim that the heat of a body is the mean kinetic energy of its molecules. Neither claim is supposed to be established by considering what we ordinarily mean by our words, or by examining what is "contained in our concepts"; quite how they are to be established is a difficult question, of course, but establishing such things is part of the traditional task of metaphysics. Coherence theorists think philosophical reflection can show that there is nothing other than coherence for truth to amount to. Their claim is therefore that truth is the same property as coherence, but that to characterize it as coherence is more adequate, more illuminating of its nature.

The coherence theory of truth is thus a radical, and at first sight highly counter-intuitive, thesis. True propositions can be said to correspond to facts, but since the theory holds that truth consists in coherence, the facts themselves are not independent of this coherence that determines truth. Coherence determines what propositions are true, and therefore what the facts are. Hence the facts are determined by what is believed, or would be under specifiable

circumstances; not, of course, that whatever is believed is true, but the truth is what coheres with the main body of beliefs, and can be equated with what would be believed by someone who believed all and only those propositions that so cohere. This is not the view of common sense. The commonsense view is that facts are what they are independently of what anyone believes about them, and independently of what anyone would believe about them under idealized circumstances – unless the idealization were of the trivial kind (such as "under those circumstances in which people would believe what is true"). Truth is, then, a matter of beliefs or propositions matching this independent reality. That gives us another sense, importantly different from the ones noticed before, in which we can speak of a correspondence theory of truth: as a name for this commonsense view. In this sense, unlike the others, the correspondence theory is incompatible with the coherence theory. It asserts just what the coherence theory denies, namely that truth consists in a relation between the proposition in question and something in the world which makes it true, where this something is taken to obtain independently of what anyone believes (or would believe) about it. Like the coherence theory, then, it is a theory about what truth consists in.

The classical proponents of the pragmatic theory are Peirce and James, and it is sometimes difficult to be sure exactly what their theory is; but as I have implied, it (usually) appears also to be a theory about what truth consists in. If it is not, it collapses into the claim that it is by its consonance with (future) experience that we discover what is true; but it would be distinctly misleading to call that epistemological thesis a theory of truth – just as it would be misleading to give that title to the claim that truth is discovered by testing for coherence amongst our beliefs. To the extent to which they reject the coherence theory, pragmatists can accept that truth is a relation between a proposition and something that is independent of what anyone believes, but only because they think of it as constituted, not by beliefs, but by experiences, which they take to be independent of and prior to our beliefs about them. Actually, though, it would be difficult to maintain quite *generally* that the truth of a belief consists in its consonance with experience, because alternative theories – inconsistent with one another – can each predict exactly the same empirical consequences. (Thus the Ptolemaic hypothesis, or the flat-earth theory, can be made to yield all the same predictions as more usual views, with sufficient adjustments to assumptions elsewhere.) Hence the pragmatist must accept coherence as a determinant of truth as well as consonance with experience; coherence, for example, with our ideas about simplicity of theory becomes of central importance for Quine (1969; cf. Peirce, 1878). So the pragmatist's position will be very much the same as that of those coherence theorists who allow a special place for experience; and it will be similarly counter-intuitive. The commonsense view of the matter regards the facts as obtaining independently of anyone's experiences of them, just as it regards them as independent of anyone's beliefs about them. So when "the correspondence theory of truth" is used as a name for this commonsense view, we can take it as holding that truth consists in a relation between a proposition and something in the world that makes it true, where this something obtains independently of anyone's experiences of it and of anyone's beliefs about it.[1]

4 Why Pragmatic and Coherence Theories are Attractive

It is no objection to a philosophical position that it is counter-intuitive. Pragmatists and coherence theorists would say that much of the attraction of what I have called the commonsense view derives from failing to distinguish it from "the correspondence theory of

truth" in one of the other senses of that term. In any case, they adopt their position, not because it seems to be what we normally think, or part of the ordinary meaning of "true," but because they feel there are strong pressures requiring us to accept what they hold about the nature of truth. These pressures are from considerations about knowledge and from considerations about meaning. To a large extent they gain their force from the fact that the commonsense view seems to leave open an awkward possibility: that our thoughts and our beliefs should wholly fail to describe the world around us. This is the possibility raised by Descartes's idea of the *malin génie*. If the world – the facts or the states of affairs that determine the truth-values of our propositions – is wholly independent of our beliefs about it and our experiences of it, what assurance could we ever have that our beliefs are really true?

The obvious answer is that, although the world is independent of our experiences and beliefs, they are not independent of the world. They are caused by it, and this fact somehow enables us to get all the assurance we need. That is what empiricists standardly say; and the reply to them is that the assurance is not provided. For all they can say, the possibility of an alternative causal origin remains, in the *malin génie*. Nothing in the content of our belief or the character of our experience can ever rule this out, for any candidate could have been placed there by the *génie*. Yet to take this suggestion seriously seems absurd. Kant's response was to distinguish between the everyday world of appearances and the world of things in themselves. About the latter we can know nothing. About the former we can know all that we ordinarily think we know, and we know that no *malin génie* deceives us; for the way things are in the world of appearances is determined conjointly by the content of our experience and the *a priori* principles that govern all our awareness. Truth in the world of appearances is a matter of coherence with these principles and with given experience. The *malin génie* hypothesis can therefore be ruled out, so far as that world is concerned: it does not cohere. Many of Kant's successors, and particularly Hegel, followed a similar line of thought, but rejected the hypothesis of things in themselves as redundant, even vacuous. This left no room for the *malin génie* even in the realm of the unknowable, for there is no such realm. Truth consists in the internal coherence of a system of beliefs. More recently others, some with very different conceptions of the world from Hegel's, have felt drawn to the same conclusion.

Often this has been because people have thought the hypothesis of an unknowable reality to be unintelligible. The verificationists of the Vienna Circle considered that an assertoric sentence could be meaningful only if it were possible to verify it, or perhaps to falsify it. Since it is not possible conclusively to verify, or to falsify, a great many of the things that we commonly say, the present-day proponents of such views require something less: properly to understand an assertoric sentence is to know under what conditions it would be warranted to assert or deny it. They support this with the argument that it is only through the association with its assertibility conditions that the meaning of an assertoric sentence could be taught, and only through the same association that it is possible to discover whether somebody knows how to use it correctly. Language is an instrument of public communication, but if one sought to convey to someone an idea that transcended all possibility of verification, it would be impossible ever to have reason to think one had been rightly understood. This at least is the position of Dummett (1978) and Wright (1987), and perhaps Wittgenstein (see Chapter 4, MEANING, USE, VERIFICATION, and Chapter 20, REALISM AND ITS OPPOSITIONS, §2).

Neither Dummett nor Wright sees it as leading to the coherence theory of truth, but others have done. Neurath (1931; 1932–1933) and Putnam (1978; 1983) are perhaps the

clearest examples of those who have explicitly adopted coherence theories as the consequence of a verificationist line of thought. It is natural to think them right in seeing the connection. Even if some of our assertoric sentences just describe what is given in experience (something Neurath disputes), clearly most of them make claims which go beyond what is presented; and on a verificationist view of things, understanding such a sentence involves grasping a set of rules to the effect that this or that circumstance establishes its truth or renders it warrantedly assertible. Now if one thought of these rules as yielding results which might be correct or incorrect, through their relation to an independent reality, one could resist any kind of coherence theory. But the verificationist does not think of them in that way. It is the rules themselves which determine what is correct or incorrect, for it is the rules which determine what verification is. There is no verification-transcendent reality with which their results can be compared. It is true that for contemporary anti-realists a particular assertion, like "Betty is in pain at *t*," may first be warrantedly assertible (in the light of her pain behavior) and then cease to be so (when we discover she is being filmed for a TV commercial); but by their own showing there can be no truth of the matter independent of whatever results the procedures of verification yield. If there were, it would have to be something that transcended verification; the possibility would again be opened up that our methods of verification are wrong.

A similar line of argument is sometimes put by saying that our conceptual scheme is, after all, our own. Our concepts, and hence the rules for their application, are provided by ourselves. Not that they are the result of our voluntary choice, of course, but besides the conceptual scheme embodied in our language and our thought there might have been equally viable alternatives. Our scheme is satisfactory, and yields truth about the world, just because it is our scheme itself (or, to be exact, coherence within it) that determines what constitutes truth. On that showing, alternative conceptual schemes might determine an alternative kind of truth; but these we reject, for they are not ours. Putnam often argues in this way, and Quine also, though Quine stresses that it is not just the coherence internal to our conceptual scheme that constitutes truth, but coherence also with experience. Davidson's position develops out of Quine's, but it differs in two essential ways. He attacks Quine for assigning the role he does to experience – beliefs can cohere, or fail to cohere, with other beliefs, but not with experience; and though we have beliefs we call empirical, their truth is determined by coherence amongst beliefs and nothing else. He also rejects the idea of alternative conceptual schemes. Nothing other than our own could constitute a conceptual scheme, for a being who lacked what is essentially our own system of beliefs could not be accounted rational, and neither concepts, beliefs, nor the language to express them could properly be ascribed to it (Davidson, 1986; for discussion of Davidson's overall approach, see Chapter 2, MEANING AND TRUTH-CONDITIONS, and Chapter 13, RADICAL INTERPRETATION). Davidson's seems to be a neat, clear-cut example of the purest form of coherence theory, though he is no longer willing to call it this himself (Davidson, 1990a; 1990b).

5 Why the Coherence Theory Fails

Despite its initial strangeness, then, there are strong reasons to adopt some version of the coherence theory of truth: reasons which may, indeed, seem compelling. Nevertheless, I think the theory is untenable: it offers an account of what truth consists in, but it is an account which depends on taking for granted the conception of truth.

It claims that the truth of p consists in its coherence with a set of beliefs that are actually held (or would be held, in non-trivially specifiable circumstances). If that were not so – if it claimed that truth amounted simply to coherence within an arbitrary set of propositions – the theory would be open to Russell's objection about Bishop Stubbs. But what about the claim that a certain belief, b_1 is actually held? If we suppose it true, in what does *its* truth consist? It must consist in coherence, for such is the theory – coherence with the other beliefs that are also held. Evidently, though, the same applies to them as well. This means that the Bishop Stubbs objection recurs after all. We can easily denominate an arbitrary set of internally coherent propositions including "Bishop Stubbs was hanged for murder," such that for each proposition p_n in the set, "It is believed that p_n" coheres with the original set. But that does not make it true that p_n is really believed; nor does the coherence of "Bishop Stubbs was hanged for murder" with the set make it true that Bishop Stubbs was hanged for murder.

What the theory requires is that it should be a fact that certain things are believed, a fact that obtains in its own right and not in virtue of some further coherence. A pure coherence theory of truth, which holds that truth *always* consists in coherence, cannot accommodate this. Nor can the impure coherence theory of Kant and the pragmatists, for it makes an exception only for truths about the content of experience. These philosophers treat claims about what people believe as being determined true or false by coherence, for they regard ascriptions of belief as part of our publicly shared theory about people's psychological states, and as having the same sort of status that theoretical claims of any other kind do.

There is in any case something rather unsatisfactory about a coherence theory of truth that is not pure. It is bound to give us a dual conception of truth: in some cases truth consists in coherence, but not in others. It is natural enough to think that we find out about the truth in different ways in different areas – we find out about mathematical truth in one way, truth about the latest news in quite another. We might express that by saying there are different criteria for truth in different areas. But that does not make it natural to think of a dual, or a multiple, conception of what truth is. We can detect warmth by touch or by thermometer, but our conception of it remains univocal. It would seem a lot less misleading to say that what coherence determines is not truth, but something else, which we might call quasi-truth. But then they would have to say that it is only in a very limited sphere that we can claim truth at all. Most of the things that we say are not true or false at all, because truth is correspondence with an independent reality and there is nothing for what we say to correspond to. They are at best quasi-true, or perhaps "useful." Pragmatists have sometimes been prepared to say this; those who take an instrumentalist view of scientific theories have often been willing to say it about the theoretical statements of the sciences. Blackburn, who regards moral and modal "truth" in this way, calls himself a quasi-realist in those areas, and contends that the language (and the logic) of "truth" and "falsity" can be used in these spheres to indicate coherence or the lack of it. Arguably it can. The trouble is that it is misleading, if not positively perverse, to use the word "true" to mark two entirely different relationships. (Wright as well as Blackburn would dissent from what I have just said; they emphasize the similarities rather than the differences in the roles assigned to "true"; Blackburn, 1984, ch. 6; Wright, 1992, ch. 4.)

6 Frege on Defining Truth

It may be felt, however, that the objection which was offered against pure coherence theories is too quick. It sounds a bit like the objection which Frege made, against the possibility of defining truth in any way at all, and opinions have differed as to whether Frege's case is convincing.

> If one were to say "A representation is true if it agrees with reality," that would achieve nothing, for in order to apply it one would have to decide, in a given case, whether a representation agreed with reality, or in other words whether it were true that the representation agreed with reality. Thus what is defined must itself be presupposed. The same would apply to every explication of the form "A is true if it has these or those properties, or stands to this or that in such-and-such a relation." The question would always arise in the particular case whether it is true that A has these or those properties, or stands to this or that in such-and-such a relation. (Frege, 1969, pp. 139–140)

What Frege calls an attempt to define truth can, I think, fairly be equated with what I have called a theory of what truth consists in. His objection to the correspondence theory, when offered as an account of what truth consists in, is that though it claims the truth of *p* consists in *p*'s correspondence with the facts, it must also admit that whether or not *p* corresponds with the facts is a matter of whether it is *true* that *p* corresponds with the facts. Similarly, the coherence theory must admit that the question whether *p* coheres with the beliefs that are held is the same as the question whether "*p* coheres with the beliefs that are held" is itself true. As Frege says, this seems to presuppose the concept that was being defined; and anyone who objects to the coherence theory along these lines will say that the problem with it arises not only over determining what it is for a belief to be actually held (or belong to the appropriate set), but more immediately over determining when one thing coheres with another. For the question whether *p* coheres with *q* is the question whether it is true that *p* coheres with *q*, but the truth of "*p* coheres with *q*" must consist in its coherence with something, say *r*. Its coherence with *r* must itself consist in the coherence (say with *s*) of "'*p* coheres with *q*" coheres with *r*,' and so we are into a vicious regress, even if we set aside the problem of determining values for *q*, *r*, *s*, and so on.

But Frege is wrong. An important difference between the correspondence theory and the coherence theory is crucial here. The correspondence theory is a theory of what truth consists in, but not a theory of what facts consist in. It can take the obtaining of a fact as ultimate. It does not have to consist in anything else. The coherence theory, however, has to hold that whether or not a fact obtains is determined by whether or not a certain proposition (the proposition that says this fact obtains) coheres in the appropriate way. The coherence theory is a theory of facts as well as of truth. The correspondence theory is a theory only of truth.

Let us take the correspondence theory first. As an account of what truth consists in, it holds that the truth of *p* consists in a relationship of correspondence between *p* and the facts. It also holds that whether or not this relationship obtains is itself a fact. It does not consist in anything else. In particular, then, it does not consist in the correspondence of "*p* corresponds with the facts" to the facts. Certainly, if *p* does correspond with the facts, then the proposition "*p* corresponds to the facts" will itself correspond to the facts; indeed, its truth – the truth of that *proposition* – consists in that correspondence. But the *fact* that *p* corresponds to the facts is a fact in its own right. Hence although there is certainly a regress of a kind, there is nothing vicious about it, any more than there is anything vicious about the observation that if *p* is true, it is true that *p* is true, and true that it is true that *p* is true. The obtaining of the correspondence relation between *p* and the facts is all that is required for "*p* corresponds with the facts" to correspond with the facts, for what the fact that "*p* corresponds with the facts" has to match is just the fact that the original correspondence relation obtains.

The coherence theorist can try a similar reply. The truth of *p* consists in its coherence with the set of beliefs S; but whether or not *p* coheres with S is something that holds in its

own right and does not consist in anything further. Certainly if "*p* coheres with S" is true, its truth consists in its own coherence with S, and the truth of "'*p* coheres with S" coheres with S' consists in coherence again. But from this we no more get a regress that is vicious than we did with the correspondence theory.

This will not do. A coherence theorist might indeed hold that it is a matter of fact, in its own right, whether or not propositions cohere with one another; but to do so would already be to make it impossible for one's coherence theory to be of the pure kind – the kind that offers an account of what truth consists in quite generally. That is because a coherence theory is inevitably a theory of facts as well as of truth. What makes something a fact, for the coherence theorist, is that the corresponding proposition is true, that is, that it coheres in the appropriate way. If it were otherwise, facts and truth would come apart. The truth of "the cat is on the mat" would consist in its coherence; but the fact that the cat is on the mat would obtain, or not obtain, quite independently of this. To hold, then, that whether or not propositions cohere with one another is simply a matter of fact, and not of any further coherence, must be to hold that the truth of "*p* coheres with *q*" does not consist in coherence, and thus to hold to the coherence theory in at best an impure form.

Coherence theorists have not usually been prepared to qualify their position in this way. Their accounts of coherence have differed radically in detail, but the pressures which led them to the coherence theory in the first place have led them also to the view that whatever it is that constitutes coherence must itself be determined by the beliefs that are held. Under "beliefs" here one must include not only the beliefs that the appropriate subjects would adumbrate, but also the rules of inference on which they rely and which decide for them what arguments are good and what arguments are bad. These are as much part of our conceptual scheme as anything else; they are as subject to the manipulation of the *malin génie* as any other beliefs, if the *malin génie* has room to manipulate at all. Hence, in their view, the coherence of our system of beliefs, or of our conceptual scheme, is a property entirely internal to it, the standards of coherence being set by the system itself. That was the theory's apparent advantage: it made truth an entirely internal matter, not a matter of matching an independent reality which seemed beyond our reach, as we could not ensure that our beliefs (and our principles of inference) reflected it correctly. Such a theory we have seen to be untenable. That certain particular beliefs are held, or would be held, under non-trivially specifiable circumstances must simply be a fact, a fact which consists in nothing further and which cannot consist in coherence. If it did, the theory would require the truth of a proposition to consist in its coherence with the set of beliefs which are held; but the truth of the claim that those beliefs are held would have to consist simply in its coherence with that set; and that will not do, for too many alternative sets of beliefs would count as "held" by that criterion, including Russell's remark about the Bishop. To put it in Frege's fashion, the theory requires that "what is defined" (the notion of truth) "must itself be presupposed."

7 The Correspondence Theory

We have seen that Frege's objection does not touch the correspondence theory of truth. It may be felt, all the same, that the correspondence theory will hardly do, for three connected reasons. In the first place, unless it is spelt out a good deal further, it hardly seems to be a *theory* at all: it just says that a true judgment or proposition is one which matches the way things are in a world that is independent of our beliefs about it and our experience of it.

Second, to show that the pure coherence theory is untenable is not to deprive of their persuasiveness the arguments that led to it. The correspondence theory seems to make the world so independent of our thoughts about it that it renders *utterly mysterious* how we can succeed in knowing about it or even thinking about it, a mystery which is not dispelled by invoking the word "correspondence." Third, this correspondence would have to be something that we constantly aim at, for the aim of our assertions is truth, but we can hardly aim at it without knowing something more substantial about it. As Putnam (1978; 1983) points out, if we grant that there is a world that is independent of our thoughts about it in the way required, then, whatever it is like, there is bound to be a large number of relations which hold between it, or the elements of it, and the things that we think and say. If it contains infinitely many elements, Putnam shows that there must be alternative ways of mapping the world on to what we say or think, alternatives which are just as systematic as the relation of correspondence can be supposed to be. By what possible feat could we pick out one of these relationships and decide that *this* is the one that we intend when we talk about correspondence? For detailed discussion of this matter, see Chapter 27, PUTNAM'S MODEL-THEORETIC ARGUMENT AGAINST METAPHYSICAL REALISM.

There have been attempts to give the correspondence theory more content, to meet the first concern at least. Two have been particularly important: that of Wittgenstein's *Tractatus* and that of Austin. For Wittgenstein (1922) the correspondence is a structural isomorphism. Propositions are pictures of facts: to the elements of the proposition correspond the elements of the relevant fact, and the way the elements of a proposition – ultimately, names – are fitted together to form the proposition again corresponds to the way the elements of reality – objects – are fitted together to constitute the fact. This can seem promising: if there is an account to be given of correspondence, what else can it amount to but some such structural isomorphism? Unfortunately, however, it does not succeed. It explains one correspondence (of the proposition with the fact) in terms of others (names with objects, structure of proposition with structure of fact) but since these are unexplained – according to Wittgenstein, inexplicable in principle – no real gain has been made. We may even feel something has been lost, if we feel that Wittgenstein's account of the way propositions are structured is altogether too Procrustean (a conclusion he later reached himself). And the theory has no answer to Putnam's objection. If there is one systematic mapping between propositions and facts that meets Wittgenstein's constraints, there are bound to be other different mappings that meet the same constraints, so that it remains obscure how we manage to intend the right one, and mysterious how we can succeed in knowing about reality.

Austin's correspondence theory is rather different. Statements, he says, are related to the world by conventions of two kinds, demonstrative and descriptive. Descriptive conventions correlate words, as they are standardly used, with "the *types* of situation, thing, event, &c., to be found in the world." Demonstrative conventions correlate words, as they are used on the particular occasion of utterance, with "the *historic* situations, &c., to be found in the world"; they are the conventions that determine reference. Then:

> A statement is said to be true when the historic state of affairs to which it is correlated by the demonstrative conventions (the one to which it "refers") is of a type with which the sentence used in making it is correlated by the descriptive conventions. (Austin, 1950, p. 116)

Austin construes "historic" broadly; still, it is arguable that his account is limited, as an account of truth, by its restriction to statements about historic states of affairs. Setting

this aside, there is something unsatisfactory about his reliance on "convention," as Strawson (1965) pointed out. Conventions govern language; what they do is to determine what is being said. Certainly, one can distinguish those conventions which one learns when learning a sentence's linguistic meaning – roughly, its Fregean sense – from those which determine its reference on a particular occasion. Taken together, these determine what is being said on the particular occasion; they determine the proposition expressed. But we were concerned with the relation between the proposition and the fact (or "historic state of affairs"). All that Austin tells us about this is that it is true when the relevant state of affairs is as it is said to be. This is disappointing. And if we try to generalize it – to take account of the fact that not every statement picks out a "historic state of affairs" and says that it is of a certain type – we are left only with what Mackie (1973) calls the notion of simple truth: that the statement or proposition is true if, and only if, things are as it says they are.

It is indeed hard to see how the correspondence theory can contrive to say more than this. The idea that the structure of the proposition somehow reflects the structure of the fact is really the only suggestion that seems at all promising, and no doubt both Austin and Wittgenstein were trying to capture it in their accounts, despite the fact that they went about it very differently. But complex structures can be said to "reflect" one another in alternative ways, because there are different ways of mapping one on to the other; and another of Strawson's objections to Austin is pertinent against any such theory. Sentences clearly have structure; arguably propositions do as well, since a proposition involves several concepts of different types; but do facts? "Facts," Strawson says, "are what statements (when true) state" (Strawson, 1950, p. 136). He is not denying that there is something in the world that makes a statement true. But the articulation of the world into facts, with a structure that reflects the propositions or the sentences we use to describe it, is simply the result of our way of thinking about it. The structure of the proposition reflects the structure of the fact, because we ascribe to the fact the structure of the proposition. Of course the world does have a structure; as I look around I can see a variety of objects strewn around on the floor, and their spatial arrangement (for example) is perfectly objective. But when I say, "This shirt is white," the corresponding fact can be said to be structured only because we think of the proposition as structured, consisting of a referring subject term and a predicative expression. Otherwise there is nothing specially structured about my shirt's being white; it just is.

The necessary and sufficient condition for *p*'s being true is that things should be as *p* says they are. If we are left with so little, do we still have a "correspondence theory"? There is reason to say so, whether or not we take it in the way that renders it inconsistent with the coherence and pragmatic theories. If we do take it in that way, then a substantial part of the point of calling it a correspondence theory can just be that it does exclude those alternatives: it maintains that truth consists in matching a wholly independent reality, and not in coherence with beliefs or experiences. Three objections were earlier raised to it, as considered in that way, and the first – that it hardly deserves the name of a theory – can thus be dismissed: the feeling that more must be said about correspondence dissolves once it is apparent there is nothing more that can be said. The second and third can, I think, be dismissed as well, though perhaps more tentatively. The third objection was that there will be various different relationships, even systematic ones, between our words or thoughts and the world, and nothing to enable us to pick out one of them as the intended correspondence. But the intended relationship is just that which gives our words the meanings they

have, and our concepts their application: then the sentence or proposition is true if things are as it says. Thus the third objection turns into the second, that it is mysterious how we can succeed in thinking or knowing anything about an independent world. On these issues there is much to be said, and this is not the place to say it, except to observe that we do seem perfectly able to say things about an independent world and show them to be true; not, perhaps, by establishing them so securely as altogether to rule out any possibility of deception by a *malin génie*, but then perhaps such a "thin and so to speak metaphysical" doubt (Descartes, 1964–1976, §vii, p. 36) need not worry us excessively.
