If we take it in the form in which it is *not* inconsistent with the coherence and pragmatic theories, then certainly the "correspondence theory" tells us nothing startling, now that we have seen that the correspondence relation cannot be informatively elucidated. In this mild form it seems uncontroversial: it just tells us that truth is a relationship between what is said or thought and some fact or state of affairs in the world, namely, the relationship that obtains when things are as they are said or thought to be. It is not committed to any ontology of facts, or any account of their structure. It is thus free from the difficulty we noticed right at the outset, of being forced to postulate vast numbers of negative and hypothetical facts for negative and hypothetical propositions to correspond to, or else to give an alternative account of their truth. They also are true when things are as they say. The theory is still however worth stating – worth, even, calling a "theory" – because it appears inconsistent with the redundancy theory, and because on further investigation it turns out not to be quite as uncontroversial as it looks.

8 The Redundancy Theory

The conflict with the redundancy theory may be more apparent than real. For the redundancy theory (Ramsey, 1927) is not a theory of what truth consists in, but a theory about the meaning of the words "is true." It holds that "… is true" can be deleted without loss. One could combine this with the thesis that truth *consists in* a relation of correspondence, because to say that is not necessarily to say anything about what we mean when we use the expression "… is true." Correspondence theorists have usually been concerned with what truth consists in, not with the analysis of meanings. There have, however, been exceptions. Austin was one. His account, cleared of the confusion over conventions, reduced to the thesis that a statement or proposition is true if, and only if, things are as it says they are. But Austin would take this, very plausibly, as giving an analysis of what we mean when we say "'Socrates is wise" is true': things are as "Socrates is wise" says they are. This is different from an analysis which allows us just to delete "… is true" and forget about it.

The redundancy theorist's alternative analysis also has some initial plausibility so long as we consider only examples of the form "*p* is true," where a value for *p* is specified; or of the form "*p* is false," which the redundancy theorist will analyze as "Not-p." Even there, it arouses two sorts of reservation. One is that "*p* is true" does seem to differ, at least in force, from "*p*," adding confirmation or endorsement or something of the sort. The second is that – as Austin claimed – it seems to say something *about p* instead of just asserting it. Wright finds in the idea lying behind these reservations material for a deeper objection: the norms that govern "*p* is true" are, he argues, inevitably different from those that govern the assertion of *p* (Wright, 1992, ch. 1). In any case, though, the theory seems to require amendment (or at least development) as soon as we move on to examples of other kinds,

as Ramsey was himself aware. Theories which try to preserve the spirit of the redundancy theory while making such amendments are often called deflationary theories.

What about the self-referential "This statement is true" and "This statement is false"? Here "is true" can hardly just be dropped out, nor can "is false" simply be replaced by a negation. Redundancy theorists have often viewed this as an *advantage* of their analysis, since it makes out such paradox-involving sentences to be incoherent. The point is moot. It is one thing to design an artificial language in which paradox-involving sentences are not well formed, and another to claim that this is true of an ordinary language like ours. The paradoxical character of "This statement is false" is not to be denied, for it can readily be understood by anyone, and a theory which argues it away cannot claim accuracy as an analysis of what we mean. This matter, however, deserves a fuller discussion than it can receive here.

At any rate, the redundancy theory cannot dismiss as ill-formed "The first statement on page 36 is true" or "Whatever the Pope says is true"; nor, indeed, have redundancy theorists ever wished to. They analyze the first as something like "There is some value of p such that p is the first statement on page 36, and p," the second as "For all values of p, if the Pope says that p, then p." If we put this more colloquially we get "Things are as the first statement on page 36 says they are" and "Things are as the Pope says they are." Here, then, the redundancy theory gives the same analysis as the amended Austinian theory.

People have sometimes expressed unease about such formulations. Often they suggest that there is something fishy about the quantification. In such examples the quantified variable occurs twice, but it is not clear that it functions in the same way both times. In its first occurrence – "If the Pope says that p" – it is arguable that it stands in for a name: or more exactly, that "that p" stands in for a name, the name of a proposition. "That Socrates is wise," or "the proposition that Socrates is wise," designates the proposition that Socrates is wise, and so in general. Indeed, if we express the point in terms of sentences instead of propositions, the matter seems clear-cut: the if-clause becomes 'if the Pope says "p,"' and the readiest device for forming a name of a sentence is to put it between quotation marks. Philosophers are very familiar with quantifiers whose bound variables stand in for names, so this first occurrence of the variable looks unproblematic. But the second cannot be handled in the same way. If it were, we should have to replace p again by a name – a sentence in quotes, or a noun phrase referring to a proposition. In that case the then-clause would not be grammatically complete: to make it so we should have to add "is true." This would remove any residual space for the thought that "is true" is in some sense redundant. It would also amount to abandoning any attempt to characterize the truth relation. The thesis, that truth is the relation between a proposition (or a sentence) and the world when things are as it says they are, would turn into the thesis that truth is the relation which stands between a proposition (or sentence) and the world when the proposition (or sentence) is true.

We could try to resolve the problem by using a different kind of quantification. We might construe the quantifiers substitutionally, or we might reflect that just as second-order quantification seems possible in which the variables are replaced by predicative expressions, so there is room for a kind of quantification in which variables are replaced by propositional or sentential expressions (cf. Grover, Camp, and Belnap, 1975/Grover, 1992, ch. 3; see also Grover, 1992, ch. 1). What is really at issue, however, is whether the variable is functioning the same way in both cases. This raises complex problems, but here it will perhaps do to make two observations. One is that if we express the matter in terms of sentences rather than propositions, the variable does appear to function in two ways, so that we need an

account of how the two occurrences relate. The other is that if we express it in terms of propositions, it is at least arguable that the variable functions in one way only.

In fact, this seems a highly plausible claim. In the antecedent it is not "*p*" but "that *p*" which looks as if it might name a proposition. The "*p*" itself does not name a proposition but expresses it, just as the "*p*" in the consequent does. In neither case is the proposition asserted, but it is characteristic of propositions that they can occur in just such contexts as these. Propositions are not objects, any more than properties are, and to assimilate the occurrence of propositional expressions to that of names would be no more sensible than to assimilate predicates to names (cf. Prior, 1971, ch. 3; for a different account – perhaps less different than it looks – see Horwich, 1990, especially pp. 18–21). Confusion is encouraged here by persistence in asking the question, "What then *are* propositions?" with the implied demand that they should turn out to be items like sentences, or sets of sentences, or the ghostly inhabitants of Frege's Third Realm. Propositions are not sentences, but what sentences express; conditions can be specified under which two sentences express the same proposition; but beyond that there is nothing more to be said. (In the same way one can provide conditions for property-identity, but one cannot go further than that in giving a non-circular answer to the question "But what *are* properties?") There is no gap between understanding the proposition that Socrates is wise and knowing what it would be for Socrates to be wise, so it would be impossible to know that the Pope had expressed that proposition without also knowing what it would be for things to be as it says they are. With sentences it is (perhaps) a different matter: one might know that the Pope had uttered a certain sentence ("Socrates is wise") without knowing anything about what it would be for things to be that way, because one might know he had uttered that sentence but not know what it meant.

Philosophers have often been reluctant to talk about propositions, because of puzzlement over what they are, and over their identity-conditions (see Chapter 39, OBJECTS AND CRITERIA OF IDENTITY; also Chapter 14, PROPOSITIONAL ATTITUDES). They have felt that clarity can only be attained by analyzing claims that might appear to be about propositions in such a way that they turn out to be about sentences. If one takes this view, one will feel constrained to adopt the first alternative above, and construe the quantification as really being over sentences. It then seems clear that the two occurrences of the variable do function differently. It is natural, if not unavoidable, to construe "If the Pope says 'Socrates is wise' then Socrates is wise," as containing a reference to a sentence in the antecedent, and then as using that same sentence (and not referring to it) in the consequent. A "sentence" here is of course more than just a string of words; it is a grammatical sentence as uttered on a particular occasion. But to explain the connection between the quoted sentence and the sentence itself, as it occurs in the consequent, we shall have to add an extra clause. The most natural way to do this would be by adding that the sentence "Socrates is wise" means that Socrates is wise: "If the Pope says 'Socrates is wise,' and if 'Socrates is wise' means that Socrates is wise, then Socrates is wise." But anyone who rejected the alternative analysis, in which the quantification was taken to be over propositions, would refuse to accept this as adequate on similar grounds. We need an account of the relation between the noun phrase "that Socrates is wise," which in the newly added clause refers to a proposition, and the "Socrates is wise" of the consequent. Such a person would make a parallel objection to any alternative to "means" which still made use of a that-clause. The only possibility, therefore, if the connection is to be expressible at all, is to use the relationship "is true if and only if." If the Pope says "Socrates is wise," and if "Socrates is wise" is true iff Socrates is wise, then Socrates is wise.

This is unfortunate. The redundancy theory held that the meaning of "Whatever the Pope says is true" is captured by "Things are as the Pope says they are"; the apparently undemanding and inoffensive correspondence theory held the same, at least when construed as an account of the meaning of "is true." But whether proposed as an account of the meaning, or as a theory of what truth consists in, it will collapse into circularity if it must, itself, make use of the notion of truth. We cannot explicate truth or "is true" by rendering "Whatever the Pope says is true" as "For every value of *s*, and every value of *p*, if the Pope says *s*, and *s* is true iff *p*, then *p*."

9 The Semantic Theory

Tarski's (1935; 1944) "semantic conception of truth" offers a possible way out of this. What Tarski shows is that for a certain rather restricted class of languages, a non-circular explication can be given of "*s* is true iff *p*," for every sentence *s* of the language concerned. It is done by providing a finite set of axioms for the language, and a set of derivation rules which permit one to deduce from the axioms a theorem of the required form – "*s* is true iff *p*" – for each sentence *s* of the language. Here *s* designates a sentence of the language under examination; it does this in terms of its structure, exhibiting it as a concatenation of simpler object-language expressions. The proof itself (and the axioms and theorems) belong to a different language, a metalanguage in which the other language is described. Tarski attached great importance to this distinction between metalanguage and object language, because he was anxious to avoid the problems raised by paradoxes like "This sentence is false." The languages he is concerned with do not permit semantic predicates like "is true" and "is false" to be meaningfully applied, within a given language, to the sentences of that language itself: only (if at all) to the sentences of some other language, for which that language is a metalanguage.

This restriction is enough to prevent Tarski's ideas from applying to ordinary languages in an unqualified form, for clearly these do allow the sort of predication he ruled out. However, it might be possible to carry over his central idea, in some way, into an explication of "is true iff" which would work for an ordinary language. The central idea is that the relationship "is true iff" is fully characterized, for the language concerned, by the axiomatic theory which permits the derivation of theorems of the form "*s* is true iff *p*" for every sentence *s* of the language. The theory does not require a prior understanding of the notion of truth. For that reason, as Tarski sets it out, it does not use the word "true" at all, but rather generates sentences of the form "*s* is T iff *p*," which are often called T-sentences. This relationship – "is T iff" – is then claimed to match our ordinary conception of truth.

The derivation rules that the theory needs are the ordinary rules of deductive logic. The axioms match each of the primitive terms of the object language with a thing or set of things in the world, thus matching the term "Socrates" with Socrates and the term "is wise" with all those things which are wise; they also include clauses which make use of the structure of the object language to enable the derivation of T-sentences. Thus where "*n*" is a name in the object language and "is F" is a one-place predicate, "*n* is F" is T iff the item that is matched with "*n*" is amongst those which are matched with "is F": from which we can infer that "Socrates is wise" is T iff Socrates is wise. Again, "*n* is F and G" is T iff the item which matches *n* is amongst those matched with "is F" and also amongst those matched with "is G," so that "Socrates is wise and sober" is T iff Socrates is wise and Socrates is sober.

The relation of matching which the axioms implicitly define is called by Tarski "satisfaction." The satisfaction conditions become much more complex, of course, when one deals with many-place predicates and sentences of more elaborate structure, and the ingenuity of Tarski's account lies in how he deals with the complexity; but the main idea is the same.

Although Tarski says his account "will explain the meaning" of "truth" (Tarski, 1944, p. 351), he is not, of course, offering a conceptual analysis, but an account of what truth consists in. I suggested that it might be helpful to a correspondence theorist who thought it would not do, as it stood, to say the correspondence relation is the relation which holds between a proposition and the world when things are as the proposition says they are, because this involves an improper quantification over propositions. It is now clear that if the correspondence theorist seeks to give an *analysis* of "is true," Tarski's work will not in fact help, because it does not contribute to an analysis. It will not help the redundancy theorist either, since the redundancy theorist also seeks to give an analysis. But to someone who holds a correspondence theory of what truth consists in, it may seem to provide just what is needed. For that reason Tarski's account has sometimes itself been called a correspondence theory.

But does it really provide what is needed? It is more like a counsel of despair. We might hope an account of what truth consists in would tell us something about the nature of truth in general, but on Tarski's view truth does not consist in anything general. His account allows us only to say that truth is a property which characterizes "The cat is on the mat" iff the cat is on the mat, "Socrates is wise" iff Socrates is wise, and so on for all the sentences of the language under discussion. Indeed, for Tarski truth could perfectly well be characterized by a long list of this kind, if the object language were so limited as only to contain a limited number of sentences. The detour through structure and satisfaction is needed only because we want to deal with languages which include indefinitely many sentences, and therefore need an account which has a limited number of axioms but yields an indefinite number of T-sentences. But it tells us nothing *general* about truth at all. A Tarskian truth-theory is a theory for a particular language, enabling us to derive T-sentences for all the sentences of that language. It is the satisfaction axioms for the language L_0 which determine what constitutes truth in L_0; the satisfaction axioms for L_1 which determine what constitutes truth in L_1; and so on. This gives us no general account of what truth consists in, and so it does not give us what we were looking for. A theory of what truth consists in was meant to be an account of what that property, truth, really is: not just truth-in-L_0, or truth-in-L_6. In fact, not only does he not give us what we wanted, Tarski goes further and assures us that we *cannot have* what we wanted. No general account of truth is possible, because it would have to be an account of truth-in-all-languages, including the language in which it is itself expressed. But a language capable of giving an account of "is true" for itself would have to be a language in which Tarski's rigorous distinction between object language and metalanguage was obliterated: a language in which sentences like "This sentence is true" are well-formed, and hence also "This sentence is false."

As already remarked, natural languages just do seem to violate the object-language/metalanguage distinction, and to give meaning to such sentences. Some people have therefore sought to retain Tarski's insights about the relation between truth and satisfaction, while abandoning that distinction and proposing alternative ways of handling the paradoxes. Kripke (1975) offers a particularly interesting attempt at this. However, any such account can still only offer us theories of truth for particular languages, and remains powerless to say anything general about what truth consists in. This is because, like Tarski, they

still explicate truth by providing a method of specifying for particular sentences of the language the circumstances in which they are to be called true: truth is the property which belongs to "The cat is on the mat" iff the cat is on the mat, to "Snow is white" iff snow is white, and so on. We could achieve the generality we are looking for only by a more radical move. Instead of introducing satisfaction as implicitly defined by a set of axioms relating the expressions of a particular language with sets of things in the world, we might just say that the satisfaction conditions relate a predicate to the things it applies to, a name to the thing it designates, and so on, and that they therefore yield an account of truth for any language by allowing the derivation of T-sentences for the sentence of that language. But *that* would bring us back to something very familiar. For simple unqualified sentences, what it tells us is that truth is the property a sentence has iff the items it designates have the properties it says they do. More generally, it tells us that truth is the property a sentence has iff things are as the sentence says they are. To say that, of course, is to say something which certain philosophers find objectionable, because of the implicit quantification over propositions: for every sentence *s* and for every proposition *p*, if *s* says that *p*, then *p*.

So we are faced with an alternative. Either we must accept that the correspondence relation can be legitimately, if not very excitingly, expressed by some such formulation as "Things are as *s* says they are," or else we must conclude, with Tarski, that nothing general can be said about truth at all: to the question "What is truth?" there is nothing to be said. At least this would have the merit of explaining why Pilate did not get an answer.

Note

1 Arguably there is room for an intermediate position here – one occupied, according to Wright (1992, ch. 3; 1995), by the semantic anti-realism explored by Dummett, Putnam, and himself. It too holds that truth consists in a relation between a proposition and something in the world that makes it true. It denies the coherence theorist's claim that the world is constituted only by coherence amongst beliefs, and holds instead that the world exists independently of what anyone believes, or would believe, about it. However, it maintains also that a statement can represent or describe the world only to the extent that there can, at least in principle, be grounds that would warrant its assertion. And it is only in so far as it can represent or describe the world that a statement is a candidate for truth. Hence, if we use the term "facts" for those aspects of reality in virtue of which true statements are true, the intermediate position would be that although the world is independent of what anyone believes, the facts are not, since what facts there are depend upon our capacities to verify (and hence on what we would believe under specifiable circumstances). This is an interesting idea. Ultimately I think the intermediate position is unstable, but to show that would be too substantial a task for the present context.

Postscript: Pluralism about Truth

MICHAEL P. LYNCH

One lesson of the above is that we seem to be able to say very little about truth in general. On the one hand, traditional theories seemed to overreach. They try to *reduce* truth to some other property, such as correspondence or coherence; as a consequence, they face counter-examples. On the other hand, broadly deflationary views (such as the redundancy theory, or the truistic version of the correspondence theory) just give up the game and admit that there is nothing informative to say about the nature of truth at all. Put starkly, the choice seems to be between two unattractive options: either truth has a single nature we can't define, or it is has no nature at all.

Over the past two decades, a third alternative has emerged. Keeping to the stark way of putting the matter, this third alternative takes it that truth has, in some sense, more than one nature, or that there is more than one way in which beliefs or propositions can be true.

This type of position has become known as *pluralism about truth*. It was originally proposed by Wright (1992; 1998; 2013) and then later developed, in a somewhat different way, by Lynch (2001a; 2004; 2009). Pluralist views typically involve two components: a non-reductive analysis of the concept of truth and an account of how more than one property can satisfy that concept.

The non-reductive account of the concept of truth favored by pluralists can be understood as a type of functionalism about the concept, according to which the secret to what truth is lies with what it does. Traditional theories of truth tended to celebrate certain intuitive features we take truth to have. The correspondence theory, for example, celebrates what we might call the Objectivity Principle: true beliefs "portray things as they are"; while the pragmatist theories celebrate the End of Inquiry Principle: true beliefs are what we aim to have at the end of inquiry. The pluralist suggests that we understand these principles not as revealing the single essence of truth, but as revealing an aspect of truth's *functional role*. Roughly speaking, "portraying things as they are" and "being the end of inquiry" are part of the truth-role. They, and other truisms about truth (such as the idea that it is correct to believe a proposition when it is true), reveal what true beliefs do. In short, the thought is that these principles tell us that true propositions are those that have a property that has a certain function in our cognitive economy.

Playing a functional role amounts to satisfying a description, one that picks out certain features possessed by anything that plays the role. Such descriptions are like job descriptions. Writing a job description involves listing the tasks anyone who has that job must do, and specifying how that job relates to others in the immediate economic vicinity. We define the job in terms of its place in a larger network of jobs, all of which are understood in relation to each other, and by weighting some aspects of the job as more important or crucial than others. In the philosophy of mind, where functionalist analyses are commonplace, so-called analytic functionalists take job descriptions for mental properties to be given by our implicit folk beliefs about those properties. In the case of a property like pain, these include truisms like "the threat of pain causes fear" and "if you are in pain, you may say 'ouch'" and "if you are hit in the head, you will probably be in pain" and so on. These platitudes tell us that a property plays the pain-role when it is related to certain other mental, behavioral, and experiential properties of an organism.[1]

Likewise, we can take the truth-role to be carved out by our common truths about truth. These truisms form a theoretical structure of sorts – one which illustrates the relationships between true propositions and propositions with various other properties such as warrant, belief, correctness, and so on. These features, as in the parallel case of functional properties in the philosophy of mind, will not be primarily causal in nature, but quasi-logical and explanatory. But the basic suggestion in both cases is the same: the unique relations that truth bears to other properties nonetheless suffice to pin it down by jointly specifying the truth-role.

This allows us to give truth-conditions for the application of the truth concept itself as follows:

(F) For every x, x is true if, and only if, x has a property that plays the truth-role.

Moreover, the functionalist can implicitly define the truth-role itself in terms of those relational features – call them the *truish features* – picked out by our common truths about

truth. Thus they can say, for example, that where a proposition P is T, T plays the truth-role just when: where P is believed, things are as they are believed to be; other things being equal, it is a worthy goal of inquiry to believe P if P is T; it is correct to believe P if and only if P is T.

One of the chief benefits of a functionalist analysis of the concept of truth is that it opens up a new way of understanding the metaphysics of truth. We saw above that properties like correspondence (understood in a robust way) aren't plausible candidates for the essence of truth. But they may well be excellent candidates to *play the truth-role*. Perhaps something like correspondence plays the truth-role for our beliefs about physical objects and their properties; perhaps something like superwarrant plays it for our normative beliefs.[2] In short, functionalism makes room for a pluralist metaphysics of truth, or the idea that different kinds of beliefs might be true in different ways.

A pluralist metaphysics of truth has significant implications. One such implication is that it would make room for the anti-deflationary idea that an appeal to truth – and its realizing properties – may be explanatorily useful. One obvious example is the nature of knowledge. If there is more than one property that can play the truth-role, then this fact might help to explain how and why moral knowledge differs in kind from knowledge about the things like cats and cars.

The functionalist view just described is more a theoretical framework than a full-fledged theory of truth. Individual advocates of the general approach can and do differ over how to fill in the details.

One thing they can differ over is the content of the common truths or platitudes that define the truth-role. Crispin Wright, an early advocate of this general approach, for example, has argued that equally or more fundamental than the truisms we've so far canvassed are platitudes linking truth with assertion and negation (Wright, 1992). Others have suggested that the number of platitudes required to demarcate the role is smaller, not larger, suggesting a view closer in spirit to some deflationary accounts.

Another area of significant disagreement concerns what to say about the nature of the truth property itself. Wright's work, for example, can be read as implying that truth is whatever property happens to play the truth-role (Wright, 1998). Thus, where that role is played by correspondence, truth is correspondence, where it is played by coherence, truth is coherence. But such a view seems to face significant problems. One such problem concerns its implication for our understanding of validity (Tappolet, 1997). According to the standard definition, valid inferences preserve a single property – truth. But now consider an inference like:

> Murder is wrong or two and two is five; two and two is not five.
> Therefore, murder is wrong.

Suppose (a) that "truth" denotes any given property that plays the truth-role and (b) that the truth-role is played by different properties in the moral and mathematical domains. If so, then the above argument does not preserve a single property contra our ordinary definition of validity.[3]

So it seems that we should not identify truth as such with the properties that realize the truth-role. A second suggestion (Pedersen and Wright, 2012) is that truth as such is a disjunctive property – a belief is true when it has the property of either corresponding or cohering. A third alternative (Lynch, 2001a) is to take "truth" to denote a higher-order

property – the property of having a property that plays the truth-role. This suggestion avoids the problem with mixed inferences – since "truth" would now denote a single property in all domains. But it comes at a price. For the point of the functionalist analysis was to define truth by way of a description of its functional role. That description implies that truth itself is a property that has the features described by our common truths about truth. But the property of having a property that has those features does not itself seem to have those features, contra our original analysis.[4]

One way out of this difficulty would be to say that truth just is the property that has the truish features essentially, but to allow that this property is itself *immanent* in its realizing properties (Lynch, 2009). Let us say that a property F is immanent in a property M if and only if it is *a priori* that F's conceptually essential features are a subset of M's features. Since it is *a priori* that every property's conceptually essential features are a subset of its own features, every property is immanent in itself. So immanence, like identity, is reflexive and transitive. But unlike identity, it is non-symmetric. Where M and F are ontologically *distinct* properties – individuated by non-identical sets of essential features and relations – and F is immanent in M, M is not thereby immanent in F.

There is more to say about immanence naturally, but even so briefly described, it seems like it might allow the functionalist what she wants.[5] Should a property of some belief such as *corresponding to reality* manifest truth, it will be *a priori* that the truish features are a subset of that property's features. Roughly put: corresponding to reality is what makes some beliefs true because being true is just part of what it is for some beliefs to correspond to reality.

The topic of truth is of perennial interest to philosophers, and involves more issues than we've had space to touch on in this chapter. Those include the liar paradox (see, e.g., Scharp, 2013), the ultimate tenability of deflationism (the articles in Lynch, 2001b), and the question of the value of truth (Lynch, 2004). Moreover, it remains an open question whether pluralism about truth in any form will prove to be successful. But it is promising. By leaving room for pluralism about the properties that play the truth-role, it avoids the scope problem plaguing traditional theories of truth. But by allowing that there is more to say about truth and its realizers than the deflationist allows, it suggests that understanding the metaphysics of truth can shed light on other issues of philosophical interest, such as the nature of knowledge or meaning. Suppose, for example, that the meaning of a sentence consists (at least in part) in its truth-conditions. If there is more than one kind of truth, then we would seem to have a clear explanation for the longstanding intuition that the meaning of ethical sentences differs in kind from the meaning of sentences about the physical world.[6]

Notes

1 For an overview of the functionalist options in the philosophy of mind, see, e.g., Kim, 1998, p. 146.
2 A belief is superwarranted, or what Crispin Wright calls superassertible, just when, roughly, its warrant would survive defeat. See Wright (1992) and Lynch (2009).
3 A related problem concerns "mixed compounds"; for discussion see Pedersen (2006), Pedersen and Wright (2012), Cotnoir (2013).
4 For other criticisms, see Wright (2010).
5 For a related view that has some of the same benefits, see Edwards (2013).
6 Thanks to Nathan Kellen for helpful comments.

Truthmaker Semantics

KIT FINE

My aim in the present chapter is to explain the basic framework of truthmaker or 'exact' semantics, an approach to semantics that has recently received a growing amount of interest, and then to discuss a number of different applications within philosophy and linguistics.

I Theory

1 Truthmakers in Metaphysics and Semantics

The idea of truthmaking is the idea of something on the side of the world – a fact, perhaps, or a state of affairs – verifying, or making true, something on the side of language or thought – a statement, perhaps, or a proposition. The idea of truthmaking has figured prominently in contemporary metaphysics and semantics. In its application to metaphysics, the thought has been that we can arrive at a satisfactory metaphysical view by attempting to ascertain *what it is*, on the side of the world, that renders true what we take to be true (as in Armstrong 1997 and 2004); and, on the semantical side, the thought has been that we can attain a satisfactory semantics for a given language by attempting to ascertain *how it is* that the sentences of the language are made true by what is in the world. In the former case, truthmaking serves as a conduit taking us from language or thought to an understanding of the world; and in the latter case, it has served as a conduit taking us from the world to an understanding of language.

I, along with other philosophers, have argued against truthmaking as a guide to metaphysics (Schnieder, 2006; Horwich, 2008; Fine, 2012a, §3). I have sometimes joked that truthmaking is fine as a guide to metaphysics as long as we junk the relata on the left, the things whose existence *makes* true, the relata on the right, the things *made* true, and the relation of *making* true. But my concern here is with truthmaking as a tool of semantics; and

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

it is worth remarking, in this regard, that the task of discerning truthmakers may be helpful for the one project even if not at all helpful for the other.

Indeed, the general focus of the two projects is very different. If our aim is to understand the world, then our focus should be on the ultimate truthmakers, on *what* in the world ultimately makes something true, and the question of *how* the truthmakers make the statements of our language true is of no great concern. But if our aim is to understand language, then our focus should be on the immediate truthmakers, not the ultimate truthmakers, and the question of *how* they make the statements of the language true will be of greatest concern. Take the statement 'there is a chair over there,' by way of example. For the metaphysical project, we may wish to give an account of the truthmakers for the statement in terms of elementary particles, let us say, and the real question of concern will be whether we can achieve a 'reduction' of the macroscopic to the microscopic. But for the semantical project, we can rest content with specifying the truthmakers in terms of ordinary macroscopic objects; and our concern in this case will not be with a reduction of the macroscopic to the microscopic but with what it is about the representational features of the statement itself that enables it to have the superficial truthmakers that it does. We see ripples on the surface of a pond; and our concern may be with what it is beneath the surface that causes the ripples or with how it is that the ripples play out over the surface, without regard for their cause.

2 *Truthmaker and Truth-Conditional Semantics*

There is a long tradition within philosophy, perhaps going all the way back to Frege (1892), of identifying the meaning of a statement with its truth-conditions, that is, with the conditions under which it is true. However, a truth-conditional account of meaning can take various different forms and it may be worthwhile to locate truthmaker semantics within a general account of this sort.

One major line of division concerns the form of the truth-conditional claims themselves. On the clausal approach, especially associated with Davidson (1967), the truth-conditions of a statement are not given as entities but by the clauses through which a theory of truth specifies when a statement is true. Thus a typical clause within such a theory might state that a conjunction 'A $\wedge$ B' is true when both of its conjuncts A and B are true. On the objectual approach, by contrast, the truth-conditions are objects, rather than clauses, which stand in a relation of truthmaking to the statements they make true. Within such an account, therefore, there is both an ontology of truthmakers and a relation of truthmaking.

Within the objectual approach, a second major line of division concerns the nature of the truthmakers. Under the most familiar version of the objectual approach, the truth-conditions of a statement are taken to be possible worlds and the content of a statement may, accordingly, be identified with the set of possible worlds in which it is true. This gives rise to 'possible worlds semantics,' which received its first systematic application to natural language in the work of Montague (1970).

Under a somewhat less familiar version of the objectual approach, the truth-conditions are not – or not, in general – taken to be possible worlds but states or situations – fact-like entities that serve to make up a world rather than being worlds themselves; and the content of a statement may, in this case, be identified with the set of verifying states or situations in which it is true. This gives rise to 'situation semantics,' which received its first systematic development in the work of Barwise and Perry (1983).

The main difference between the two kinds of semantics turns on the question of completeness: the truth-value of any statement will be settled by a possible world (at least to the extent that it is capable of being settled), whereas the truth-value of a statement may not be settled by a state or situation. The state of the weather in New York, for example, will not settle whether it is raining in London.

Within situation semantics itself, there is a third major line of division. For whereas it is tolerably clear what it takes for a statement to be true at a possible world, considerable unclarity surrounds the question of what it is for a statement to be true in a situation. There are at least three different conceptions of the truthmaking relation that one might adopt. We might call them *exact*, *inexact*, and *loose*; and they are successively broader. Thus each exact verifier of a statement is an inexact verifier and each inexact verifier a loose verifier.

Loose verification is a purely modal notion. A state or situation s will loosely verify a statement just in case the state necessitates the statement, that is, just in case it is impossible that the state obtain and the statement not be true. Exact and inexact verification, by contrast, require that there be a relevant connection between state and statement. With inexact verification, the state should at least be *partially* relevant to the statement; and with exact verification, it should be *wholly* relevant. Thus the presence of rain will be an exact verifier for the statement 'it is rainy'; the presence of wind and rain will be an inexact verifier for the statement 'it is rainy,' though not an exact verifier; and the presence of wind will be a loose verifier for the statement 'it is rainy or not rainy' (since the statement is true no matter what), while failing to be an inexact verifier. Loose and inexact verification are monotonic or 'hereditary': if a state necessitates or is partially relevant to the truth of a statement, then so is any more comprehensive state. But exact verification is not hereditary; the statement 'it is rainy' will be exactly verified by the presence of rain, for example, by not by the presence of rain and wind.

Here, in summary form, is a diagram of the various options:

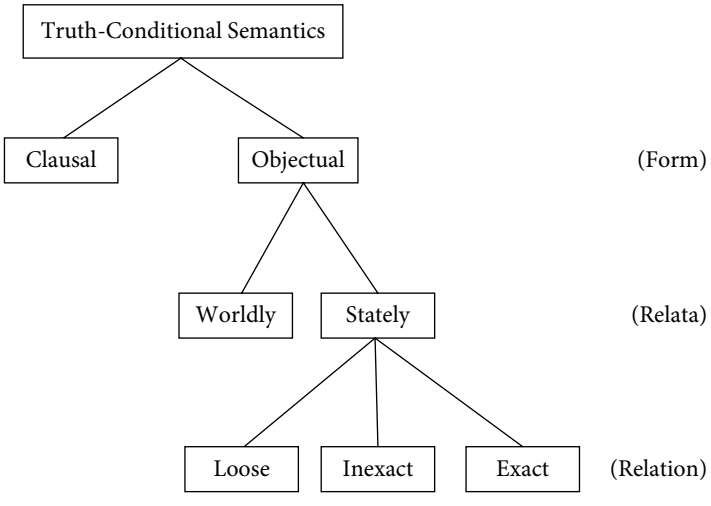

Figure 22.1

And within this framework, what I am calling 'truthmaker semantics' lies to the far right, with verification objectual, stately, and exact.

3 *Exact Verification*

When we survey the literature on situation semantics, we find that there has been little interest in the loose version of the semantics (though the work of Humberstone, 1981, and Rumfitt, 2012, is something of an exception). Most of the work – beginning with Barwise and Perry (1983) and extending to more recent work in the formal semantics for natural language (as typified by Kratzer, 2014) – has adopted the inexact approach or some variant of it.

The exact approach, on the other hand, has had a somewhat checkered career. Van Fraassen's "Facts and tautological entailments" (1969) was the first paper to present an exact semantics for classical logic. But it has been the fate of the semantics presented in that paper to be constantly rediscovered. Thus one reincarnation has been in the work of L. K. Schubert and his collaborators (Hwang and Schubert, 1993); another in the work of Stelzner (1992) on deontic logic; and another in some of the work of the school of Inquisitive Semantics at Amsterdam (Groenendijk and Roelofsen, 2010). I myself hit upon the idea of the semantics in the late 1960s and briefly mentioned its application to the problem of 'Disjunctive Simplification' in my review of Lewis's book on counterfactuals (Fine, 1975). However, it is only very recently that the full range and potential of the approach – as evidenced by the work of Aloni and Ciardelli (2013), Angell (1977; 1989; 2002), Fine (2012b; 2012c; 2013; 2014a; 2014b; 2015a; 2015b; 2015c; 2015d; 2015e; 2016), Gemes (1994; 1997), Moltmann (2007), van Rooij (2013), and Yablo (2014), among others – has begun to be appreciated.

It should also be mentioned, though this may not be evident to those working within only one of the respective fields, that there is an intimate connection between the recent semantical work on truthmaking and the recent metaphysical work on ground (Correia and Schnieder, 2012, is a recent collection of papers on ground). For if some statements A_1, A_2, … are to constitute a ground for another statement C, then they must be wholly relevant to the other statement's being the case; and, indeed, we might think of the notion of exact verification as being obtained through a process of ontological and semantic ascent from a claim of ground. For we first convert the statements A_1, A_2, … into the corresponding facts f_1, f_2, … (that A_1, A_2, …, obtain) and then take the sum f of the facts f_1, f_2, … to be an exact verifier for the truth of C. It is my belief that it is the notion of ground rather than the notion of truthmaking that is most relevant to the metaphysical project of discerning the nature of reality; and so it is of interest that this notion, of fundamental significance to metaphysics, can be 'reworked' in this way into a notion of fundamental significance to semantics.

4 *State Spaces*

In setting up the possible worlds semantics, we suppose given a 'pluriverse' of possible worlds; and, in applying the semantics, there is no need to suppose that possible worlds have any internal mereological structure – they can simply be taken to be undifferentiated 'blobs,' perhaps externally related by certain accessibility relations but with no internal mereological structure of their own.

For the purposes of setting up the truthmaker semantics, we suppose given a 'state space' of states. But it will be important, in applying the semantics, to suppose that the states, in contrast to possible worlds, are endowed with mereological structure. We must allow, for example, that one state may be a part of another, as when the presence of rain is part of the presence of rain and the wind, or that two states may fuse to a single composite state, as when the presence of rain and the presence of wind fuse to the presence of rain and wind.

It is also important in applying the semantics to appreciate that the term 'state' is a mere term of art and need not be a state in any intuitive sense of the term. Thus facts or events or even ordinary individuals could, in principle, be taken to be states, as long as they are capable of being endowed with the relevant mereological structure and can be properly regarded as verifiers. We allow the states, whatever they might be, to be possible as well as actual (as with Gore winning the presidency in 2001); and we even allow impossible states (as with Gore both winning and losing the presidency in 2001). Thus verification will have a counterfactual flavor; a verifying state is one that *would* make a given statement true were it to obtain, not necessarily one that *does* make the statement true.

From a purely mathematical point of view, we may take a *state space* to be an ordered pair $(S, \sqsubseteq)$, where S (states) is a non-empty set and $\sqsubseteq$ (part) is a binary relation on S. We suppose that the relation $\sqsubseteq$ is a *partial order*, that is, that it conforms to the following three conditions for any states s, t, and u of S:

(i) Reflexivity: $s \sqsubseteq s$
(ii) Anti-symmetry: $s \sqsubseteq t$ and $t \sqsubseteq s$ implies $s = t$
(iii) Transitivity: $s \sqsubseteq t$ and $t \sqsubseteq u$ implies $s \sqsubseteq u$.

We wish to impose a further condition on a state space, although this will call for two additional definitions. Given a subset $T \subseteq S$ of states, we say that s is an *upper bound of* T if it contains each state of T, that is, if $t \sqsubseteq s$ for each $t \in T$, and we say that s is a *least upper bound* (lub) *of* T if s is an upper bound of T and if it is included in any upper bound of T, that is, if $s \sqsubseteq s'$ for any upper bound s' of T. We then require that a state space be *complete* in the sense that every subset $T \subseteq S$ of states have a least upper bound.

The least upper bound of $T \subseteq S$ is unique (since if s and s' are least upper bounds, then $s \sqsubseteq s'$ and $s' \sqsubseteq s$ and so, by anti-symmetry, $s = s'$). We denote it by $\sqcup T$ and call it the *fusion of* T (or of the members of T). When $T = \{t_1, t_2, \ldots\}$, we may write $\sqcup T$ more perspicuously in the form $t_1 \sqcup t_2 \sqcup \ldots$; and so, in particular, $s \sqcup t$ will be the least upper bound of $\{s, t\}$. For many applications, we need only assume the existence of $s \sqcup t$ and not the existence of $t_1 \sqcup t_2 \sqcup \ldots$ for arbitrary $t_1, t_2, \ldots$.

The state space $(S, \sqsubseteq)$, as we have defined it, does not embody the distinction between possible and impossible states; for all that we have said, each state in S might be an impossible state. In order to give recognition to the distinction, we may take a *modalized state space* to be an ordered triple $(S, S^\Diamond, \sqsubseteq)$, where $(S, \sqsubseteq)$ is a state space as before and $S^\Diamond$ (possible states) is a non-empty subset of S. We make one assumption about $S^\Diamond$, namely:

Closure under Part $t \in S^\Diamond$ whenever $s \in S^\Diamond$ and $t \sqsubseteq s$.

Parts of possible states are also possible states. The interest of modalized state spaces is that they enjoy both a mereological structure (as represented by $\sqsubseteq$) and a modal structure (as represented by $S^\Diamond$); and the interaction of the two enables us to define many notions of significance. We may say, in particular, that two states s and t are *compatible* if their fusion $s \sqcup t$ is a possible state (i.e., a member of $S^\Diamond$) and *incompatible* if their fusion $s \sqcup t$ is not a possible state. Thus the possible state of my being cold and the possible state of my being hungry will presumably be compatible since the state of my being cold and hungry is a possible state, while the possible state of my being cold and the possible state of my being hot will presumably be incompatible since the state of my being both cold and hot is not a possible state.

We may also employ the resources of a modalized state space to say when a state corresponds to a possible world. For given a modalized space $(S, S^{\Diamond}, \sqsubseteq)$, we may say that the state s is a *world-state* if it is possible and if any state is either a part of s or incompatible with s. Thus a world-state must positively include or exclude any other state. Given the notion of a world-state, we may then say that the space $(S, S^{\Diamond}, \sqsubseteq)$ is a *W-space* if every possible state of S is part of a world-state. Thus a W-space will, in effect, contain the pluriverse of possible worlds. However, very few applications require the assumption that the state space be a W-space and so, from this perspective, the postulation of possible worlds is a gratuitous assumption that serves no real purpose.

It should be noted that our approach to states is highly general and abstract. We have formed no particular conception of what they are; and nor have we assumed that there are 'atomic' states, from which all other states can be obtained by fusion. Nearly all of the existing literature on the topic has failed to adopt such a neutral perspective. Thus states are often identified with sets of possible worlds (where the worlds themselves might be identified with sets of sentences) or it is assumed that all states are constructed from atomic states which are somehow isomorphic with the atomic sentences of the language under consideration.

Nothing is gained by this lack of generality or abstraction and a great deal is lost. For one thing, the particular identifications or assumptions may not be appropriate in certain contexts. One might well think, for example, that a progressive statement such as 'this is moving' is not made true by any atomic state but by the motions of the object over successively shorter intervals of time; and if one takes a state to be a set of possible worlds, then one denies oneself the possibility of distinguishing between different necessary states or different impossible states. The technical development of the subject also requires a more abstract approach. For one will want to perform certain constructions on state spaces (forming product spaces, for example, or congruent spaces) in which the special identifications of or restrictions on the original spaces are lost.

The abstract approach to modal logic championed by Kripke's early work (in which possible worlds are simply regarded as arbitrary points, rather than as models or sets of sentences) has been a great boon to the formal development of modal logic; and it is to be hoped that future researchers will appreciate that there are similar benefits to be gained by adopting a more abstract approach to the truthmaker framework as well.

5 *Sentential Semantics for Exact Verification*

A good test for any proposed semantical framework is its ability to deal with classical sentential logic; and so let me show how we might give such a semantics within the truthmaker framework.

Recall the standard possible worlds semantics for sentential logic. For the case of negative, conjunctive, and disjunctive statements we have the following clauses:

(ii) a world verifies $\neg$A iff it does not verify A;
(iii) a world verifies a conjunction A $\wedge$ B iff it verifies A and verifies B;
(iv) a world verifies a disjunction A $\vee$ B iff it verifies A or verifies B.

Let us now give the corresponding clauses under the truthmaker approach. Our aim is not simply to say when a statement is true *at* a world but to say what it is *in* the world that

makes it true and in such a way that the truthmaker is wholly relevant to the statement it makes true. To this end, we shall find it helpful to give separate clauses for when a statement is verified and for when it is falsified.[1] Here are the clauses for negation, conjunction, and disjunction, which are split into two parts – one for verification and the other for falsification:

(ii)′ A state verifies a negative statement ¬A just in case it falsifies the negated statement A;
a state falsifies the negative statement ¬A just in case it verifies the negated statement A.

(iii)′ A state verifies a conjunction A ∧ B just in case it is the fusion of states that verify the respective conjuncts A and B;
a state falsifies the conjunction A and B just in case it falsifies A or falsifies B.

(iv)′ A state verifies a disjunction A ∨ B just in case it verifies one of the disjuncts A or B;
a state falsifies the disjunction A ∨ B just in case it is the fusion of states that falsify the respective disjuncts A and B.

Clearly, these clauses are all very plausible, once we have in mind that our interest is in the notion of *exact* verification: what exactly verifies a conjunction is the fusion of the verifiers for its conjuncts; what exactly verifies a disjunction is a verifier for one of the disjuncts; and similarly for the falsification of a conjunction or of a disjunction.

Let us now provide a more technical exposition of the semantics. We suppose given an infinitude of atomic sentences p_1, p_2, …. Formulas of the sentential language are then constructed from the atomic sentences using the Boolean operators ∧, ∨, and ¬ in the usual way.

A (*state*) *model* $\boldsymbol{M}$ is an ordered triple $(S, \sqsubseteq, |\cdot|)$, where $(S, \sqsubseteq)$ is a state space, as before, and $|\cdot|$ (valuation) is a function taking each sentence letter p into a pair (V, F) of subsets of S – intuitively, the set $|p|^+ = V$ of its verifiers and the set $|p|^- = F$ of its falsifiers.

When a model $\boldsymbol{M} = (S, S^\Diamond, \sqsubseteq, |\cdot|)$ is constructed over a modalized state space $\boldsymbol{S} = (S, S^\Diamond, \sqsubseteq)$, one might want to take into account the interaction between the verifiers V and the falsifiers F of any given atomic sentence p. There are then two plausible conditions that might be imposed:

Exclusivity: No verifier is compatible with a falsifier (i.e., no member of V is compatible with a member of F);
Exhaustivity: Any possible state is compatible with a verifier or with a falsifier (i.e., each possible state is compatible with a member of V or with a member of F).

Exclusivity corresponds to the assumption that no statement is both true and false (which is how things would be if a verifier were compatible with a falsifier); and Exhaustivity corresponds to the assumption that every statement is either true or false (since no possible state could exclude the statement being either true or false). Of course, either of these assumptions could be dropped if one wanted to allow either truth-value gluts (a statement being both true and false) or truth-value gaps (a statement being neither true nor false).

Given a model $\boldsymbol{M} = (S, \sqsubseteq, |\cdot|)$, we may now define what it is for an arbitrary formula A to be *verified by* a state s (s ||- A) or *falsified by* a state s (s -|| A):

(i)$^+$ s ||- p if $s \in |p|^+$;
(i)$^-$ s -|| p if $s \in |p|^-$;
(ii)$^+$ s ||- ¬B if s -|| B;
(ii)$^-$ s -|| ¬B if s ||- B;
(iii)$^+$ s ||- B ∧ C if for some states t and u, t ||- B, u ||- C, and $s = t \sqcup u$;
(iii)$^-$ s -|| B ∧ C if s -|| B or s -|| C;
(iv)$^+$ s ||- B ∨ C if s ||- B or s ||- C;
(iv)$^-$ s -|| B ∨ C if for some t and u, t -|| B, u -|| C, and $s = t \sqcup u$.

Here (ii)$^+$ and (ii)$^-$ correspond to (ii)′ above, (iii)$^+$ and (iii)$^-$ to (ii)′, and (iv)$^+$ and (iv)$^-$ to (iv)′.

6 *Some Features and Consequences of the Semantics*

I should like to discuss some noteworthy features of the semantics, especially in so far as they stand in contrast to those of other, more familiar, semantical schemes.

One immediate odd consequence of the clauses is that p ∧ p may not have the same verifiers as p. For suppose that s and t are the two verifiers of p, where neither is a part of the other. Then $s \sqcup t$ is a verifier for p ∧ p by clause (iii)$^+$ but not a verifier for p. I believe that this odd consequence is not a problem for natural language applications but that it may be a problem for more theoretical applications. If, for example, our interest is in the partial truth or confirmation or verisimilitude of a statement, then it seems to me that we would not want to distinguish in this way between the statements p and p ∧ p.

We may avoid this odd consequence, if we wish, by requiring that a verifier for A ∧ B should also be a verifier for A ∨ B (and, likewise, by requiring that a falsifier of A ∨ B should also be a falsifier for A ∧ B). Thus (iii)$^-$ and (iv)$^+$ now become:

(iii)$^{*-}$ s -|| B ∧ C if s -|| B or s -|| C or s -|| B ∨ C
(iv)$^{*+}$ s ||- B ∨ C if s ||- B or s ||- C or s ||- B ∧ C.

and we obtain what might be called the 'inclusive' semantics. It is characteristic of the inclusive semantics that the set $\{s \in S: s \text{ ||- A}\}$ of verifiers of any statement A should always be *closed under fusion*, that is, if $s_1, s_2, \ldots$ are one or more verifiers of A then so is their fusion $s_1 \sqcup s_2 \sqcup \ldots$.

There are a number of other variants of the clauses that might also be considered (as in Fine, 2015b, or Groenendijk and Roelofsen, 2010) but, in the interests of simplicity, we shall usually confine our attention in what follows to the original non-inclusive clauses.

It is evident from the above account that exact verification need not be hereditary. Indeed, there is nothing to prevent an atomic sentence p being exactly verified by a single state p and yet not verified by any distinct state $p' \sqsupseteq p$. However, if the verifiers of all the atomic sentences $p_1, p_2, \ldots$ are hereditary, that is, if s ||- p_k and $s' \sqsupseteq s$ implies s' ||- p_k, then it can be shown that the verifiers of all formulas A whatever will be hereditary, that is, that s ||- A and $s' \sqsupseteq s$ implies s' ||- A. Thus the failure of hereditariness arises from the behavior of the atomic sentences and is not attributable to the behavior of the sentential connectives.

It should also be evident that there is no reason in general to think that the exact verifiers will be minimal. Say that the state s *minimally verifies* the formula A if s exactly verifies A and if no proper part of s exactly verifies A (i.e., if $s' \sqsubseteq s$ and $s' \Vdash A$ implies $s' = s$). Now suppose that p is the sole verifier of p and q the sole verifier of q, with $q \not\sqsubseteq p$. Then p and $p \sqcup q$ are both verifiers of $p \vee (p \wedge q)$, with $p \sqcup q$ non-minimal since it contains the verifier p as a proper part. Indeed, there is no reason to suppose that a statement with verifiers need have any minimal verifiers at all. In the case of 'this is moving,' for example, we may well maintain that any verifier (the motion of the object through an interval of time) will contain another verifier as a proper part.

There has been a persistent tendency in the literature (we might call it 'minimalitis') to start off with a hereditary notion of verification and then attempt to get the corresponding notion of minimal verification, or some variant of it, to do the work of exact verification (as in the account of 'exemplification' in Kratzer, 2014). But if I am correct, all such attempts are doomed to failure. The relevant sense in which an exact verifier is wholly relevant to the statement it makes true is not one which requires that no part of the verifier be redundant but is one in which each part of the verifier can be seen to play an active role in verifying the statement. Thus the verifier $p \sqcup q$ of $p \vee (p \wedge q)$ can be seen to play such an active role, even though the part q is redundant, because of its connection with the second disjunct $(p \wedge q)$.

It is important to note that within the present semantics (and this is also true of a number of variants), two formulas A and B may have the same verifiers while $\neg A$ and $\neg B$ do not have the same verifiers. For let A be the formula $p \wedge (q \vee r)$ and B the formula $(p \wedge q) \vee (p \wedge r)$. Then it is readily verified that A and B will have the same verifiers (in any model). For the verifiers of $p \wedge (q \vee r)$ will be the fusions $p \sqcup s$ of a verifier p for p and a verifier s for $(q \vee r)$ by clause $(iii)^+$ above and hence will be the fusions $p \sqcup q$ of a verifier p for p and a verifier q for q or the fusions $p \sqcup r$ of a verifier p for p and a verifier r for r by clause $(iv)^+$, and these are exactly the verifiers of $(p \wedge q) \vee (p \wedge r)$ (again by $(iii)^+$ and $(iv)^+$). However, the verifiers for $\neg A$ and $\neg B$ may not be the same in this case. For suppose p is the sole falsifier of p, q of q, and r of r. Then by clauses $(iii)^-$ and $(iv)^-$, $p \sqcup r$ is a falsifier of $(p \wedge q) \vee (p \wedge r)$ but not of $p \wedge (q \vee r)$ (unless, of course, $p \sqcup r$ happens to be identical to p or to $q \sqcup r$).

This means that it is essential to define verification by means of a double induction on verification and falsification, as we did above, since the verifiers of the negation statement $\neg A$ cannot in general be determined from the verifiers of the negated statement A. It also means that we must complicate our definition of *proposition*. Within the possible worlds framework, the proposition (or content) expressed by a bivalent statement A can be identified with the set of worlds at which it is true. There is no need to bring in the worlds at which it is false, since these will simply be the worlds at which it is not true. Within the present framework, we might similarly identify the proposition expressed by a bivalent statement A with the set of its verifiers $V = \{s \in S: s \Vdash A\}$. We thereby obtain what I call a *unilateral* conception of propositionhood. But this conception will not be adequate if we wish to able to discern the proposition expressed by $\neg A$ from the proposition expressed by A. In this case, we should adopt a *bilateral* conception of propositionhood, according to which the proposition expressed by a statement A is a *pair* (V, F) of sets of states consisting of its set of verifiers $V = \{s \in S: s \Vdash A\}$ and its set of falsifiers $F = \{s \in S: s \dashv\!\Vdash A\}$ (in effect, this was already presupposed in our previous account of the valuation function $|\cdot|$). Under the unilateral conception of propositions, we might then take the conjunction $P \wedge Q$ of two propositions P and Q to be $\{p \sqcup q: p \in P \text{ and } q \in Q\}$ and we might take their disjunction $P \vee Q$

to be $P \cup Q$ (i.e., $\{s: s \in P \text{ or } s \in Q\}$); and, under the bilateral conception of propositions, we might take the negation of the proposition (P, P') to be (P', P), the conjunction of the propositions (P, P') and (Q, Q') to be $(P \wedge Q, P' \vee Q')$, and their disjunction to be $(P \vee Q, P' \wedge Q')$ (in conformity with clauses $(ii)^+$–$(iv)^-$ above).

One interesting aspect of the present approach is that it enables us to *define* the notions of inexact and loose verification. Thus we may say that *s inexactly verifies* A – in symbols, $s \,||{>}\, A$ – if *s* contains an exact verifier of A, that is, if for some state $s' \sqsubseteq s$, $s' \,||\text{-}\, A$, and we may say (within a modalized model) that *s loosely verifies* A – in symbols, $s \,|{=}\, A$ – if *s* is incompatible with any exact falsifier of A, that is, if *s* is incompatible with *t* whenever $t \text{ -}|| A$. It turns out that the 'reverse' definitions are not possible: exact verification cannot be defined in terms of inexact verification; and inexact verification cannot be defined in terms of loose verifications. Thus the different notions of verification – loose, inexact, and exact – involve a progressively greater commitment to what might be involved in the verification of a given statement; and we obtain the greatest flexibility in developing a theory of verification by taking the exact notion as primitive and seeing the other notions as off-shoots of the exact notion.

A further interesting aspect of the approach is that it naturally gives rise to two notions of consequence. For there are two natural ways of defining the relation of consequence between propositions *P* and *Q* – in terms either of conjunctive part or of disjunctive part. We may say that *P* is a *conjunctive part of Q* if *Q* is the proposition $P \wedge R$ for some proposition *R*; and we may say that *P* is a *disjunctive part of Q* if *Q* is the proposition $P \vee R$ for some proposition *R*. We may then define *Q* to be a consequence of *P* either when *Q* is a conjunctive part of *P* or when *P* is a disjunctive part of *Q*.

Under the identification of classical truth-functionally equivalent propositions (and hence, in particular, under the possible worlds approach), the two relations of consequence will coincide. For if *Q* is a conjunctive part of *P*, that is, if *P* is the proposition $Q \wedge R$ for some *R*, then *Q* will be the proposition $P \vee Q$ (given the classical truth-functional equivalence of *Q* to $(Q \wedge R) \vee Q$) and hence *P* will be a disjunctive part of *Q*; and if *P* is a disjunctive part of *Q*, that is, if *Q* is the proposition $P \vee R$, then *P* will be the proposition $Q \wedge P$ (given the classical truth-functional equivalence of *P* to $(P \vee R) \wedge P$) and hence *Q* will be a conjunctive part of *P*.

However, within the truthmaker approach the two relations come apart. Let us, for simplicity, work with a unilateral conception of propositions, under which a proposition is identified with its set of verifiers. Then the relation of *P*'s being a disjunctive part of *Q* will correspond most closely to the classical notion of consequence, since this is the relation that will hold between *P* and *Q* when every verifier of *P* is a verifier of *Q* (just as *Q* will be a consequence of *P* under the possible worlds approach when every world of *P* is a world of *Q*). But the notion of *P*'s being a conjunctive part of *Q* will be very different and has no real counterpart within the possible worlds approach. *P* will be a conjunctive part of *Q* only if (and, under certain simplifying assumptions, if and only if) the following two conditions obtain:

(i) every verifier of *P* is included in a verifier of *Q*; and
(ii) every verifier of *Q* contains a verifier of *P*.

Thus the proposition $P = \{p, q\}$ will be a conjunctive part of the proposition $Q = \{p \sqcup r, p \sqcup s, q \sqcup r, q \sqcup s\}$, since *Q* is the conjunction of $P \wedge R$, for *R* the proposition $\{r, s\}$. But, of course, *Q* is not, in general, a disjunctive part of *P*.

The relation of conjunctive part corresponds to the intuitive notion of *partial content* – of what is conveyed, in whole or part, by what is said. Thus in saying that Fido is a cocker spaniel, I convey, in part, that he is a spaniel and that he is a dog, but I do not convey, even in part, that he is a dog or a cat. In the one case, the content of 'Fido is a spaniel' is part of the content of 'Fido is a cocker spaniel' while, in the other case, the content of 'Fido is a dog or a cat' is not part of the content of 'Fido is a dog.'

The existence of the two relations of consequence may be of some methodological significance to the study of linguistics. For it is often assumed that intuitions of validity provide a key piece of data (some might think, *the* key piece of data) in the construction of a formal semantics for natural language. But, if I am right, then we should be somewhat more sensitive to the different inferential relationships that might be in play and it will be of particular importance to distinguish the subclass of inferential relationships that preserve content (as in the example above) and not merely truth.

There is one final aspect of truthmaker semantics which I should mention and which is of the greatest importance. It will have been noted that in specifying the verifiers of truth-functionally complex statements, we have not restricted ourselves to possible states. For given that p is a verifier for p and q is a verifier for q, we take $p \sqcup q$ to be a verifier for $p \wedge q$ even if p and q are incompatible and $p \sqcup q$ is therefore an impossible state. But it is not just that we do not restrict ourselves to possible states, we do not even make use of the distinction between possible and impossible states. The distinction is simply irrelevant in specifying the semantics for the connectives.

Of course, the distinction between possible and impossible will be required in providing an account of modal notions. We may want to say, for example, that 'necessarily, A' is true if every *possible* state is compatible with a verifier of A. Or again, we will say that s loosely verifies A (a modal notion) if s is *incompatible* with any falsifier of A and that C is a classical consequence of A (another modal notion) if every loose verifier of A is a loose verifier of C. But the present point of view is that there is nothing in the general notion of content or meaning or in the most general logical devices that requires us to draw the distinction between possible and impossible states. This freedom from the modal thinking that has been so characteristic of the more usual approaches to semantics is, I believe, one of the most distinctive and liberating aspects of the present approach.

7 Quantifiers

I have so far said nothing about the quantifiers. There are a number of different options for extending the clauses for the connectives to the quantifiers. But rather than considering them all, let me discuss one especially simple option, with an indication of how it might be extended to other cases.

One very general strategy for providing a semantics for quantificational statements is to reduce them to the corresponding truth-functional statements. Thus suppose the universal quantifier $\forall x$ ranges over the individuals $a_1, a_2, \ldots$.Then given that $a_1, a_2, \ldots$ are constants for the corresponding individuals $a_1, a_2, \ldots$, we might take the content of $\forall x \varphi(x)$ to be the same as the content of the conjunction $\varphi(a_1) \wedge \varphi(a_2) \wedge \ldots$; and, similarly, we might take the content of the existential quantification $\exists x \varphi(x)$ to be the same as that of the disjunction $\varphi(a_1) \vee \varphi(a_2) \vee \ldots$.

If we apply this general strategy to the present case, we arrive at the following clauses for the two quantifiers:

(v) a state verifies $\forall x\varphi(x)$ if it is the fusion of verifiers of its instances $\varphi(a_1)$, $\varphi(a_2)$, …;
a state falsifies $\forall x\varphi(x)$ if it falsifies one of its instances.
(vi) a state verifies $\exists x\varphi(x)$ if it verifies one of its instances $\varphi(a_1)$, $\varphi(a_2)$, …;
a state falsifies $\exists x\varphi(x)$ if it is the fusion of falsifiers of its instances.

Within a more formal treatment, we might introduce variables, predicates, and quantifiers into the language and define a formula (of the resulting first-order language) in the usual way. A *model* ***M*** is now an ordered quadruple $(S, A, \sqsubseteq, |\cdot|)$, where $(S, \sqsubseteq)$ is a state space, as before, A (individuals) is a non-empty set, and $|\cdot|$ (valuation) is a function taking each n-place predicate F and any n individuals $a_1, a_2, \ldots, a_n$ of A into a pair (V, F) of subsets of S – where, intuitively, V is the set of states which verifies F of $a_1, a_2, \ldots, a_n$ and F is the set of states which falsify F of $a_1, a_2, \ldots, a_n$.

We may now introduce constants $a_1, a_2, \ldots$ into the language, one for each of the distinct individuals $a_1, a_2, \ldots$ that compose A. We then have the following clauses for the closed atomic and quantificational formulas:

(i)$^+$ $s \Vdash Fa_1a_2 \ldots a_n$ if $s \in |F, a_1, a_2, \ldots, a_n|^+$;
(i)$^-$ $s \nVdash Fa_1a_2 \ldots a_n$ if $s \in |F, a_1, a_2, \ldots, a_n|^-$
(v)$^+$ $s \Vdash \forall x\varphi(x)$ if there are states $s_1, s_2, \ldots$ with $s_1 \Vdash \varphi(a_1), s_2 \Vdash \varphi(a_2), \ldots$ and $s = s_1 \sqcup s_2 \sqcup \ldots$;
(v)$^-$ $s \nVdash \forall x\varphi(x)$ if $s \nVdash \varphi(a)$ for some individual $a \in A$.
(vi)$^+$ $s \Vdash \exists x\varphi(x)$ if $s \Vdash \varphi(a)$ for some individual $a \in A$;
(vi)$^-$ $s \nVdash \exists x\varphi(x)$ if there are states $s_1, s_2, \ldots$ with $s_1 \nVdash \varphi(a_1), s_2 \nVdash \varphi(a_2), \ldots$ and $s = s_1 \sqcup s_2 \sqcup \ldots$.

Just as we can allow for a more inclusive clause for the falsification of a conjunction or the verification of a disjunction (clauses (iii)$^{*-}$ and (iv)$^{*+}$ from §I6 above), so we can allow for a more inclusive clause for the falsification of a universal quantification and the verification of an existential quantification:

(v)$^{*-}$ $s \nVdash \forall x\varphi(x)$ if for some distinct individuals $a_{k1}, a_{k2}, \ldots, s_{k1} \nVdash \varphi(a_{k1}), s_{k2} \nVdash \varphi(a_{k2}), \ldots$, and $s = s_{k1} \sqcup s_{k1} \sqcup \ldots$;
(vi)$^{*+}$ $s \Vdash \exists x\varphi(x)$ if for some distinct individuals $a_{k1}, a_{k2}, \ldots, s_{k1} \Vdash \varphi(a_{k1}), s_{k2} \Vdash \varphi(a_{k2}), \ldots$, and $s = s_{k1} \sqcup s_{k1} \sqcup \ldots$.

The difference between the two sets of clauses is that, in the first case, a universal quantification is only falsified and an existential quantification only verified via a single instance while, in the second case, the quantificational statements are verified or falsified via one or more instances.

One problem with these clauses is that they presuppose a fixed domain of individuals. For suppose that the actual individuals are $a_1, a_2, \ldots$ and that a is a merely possible individual (distinct from each of $a_1, a_2, \ldots$). Then in a possible world in which a exists, the truth of the instances $\varphi(a_1), \varphi(a_2), \ldots$ is not sufficient to guarantee the truth of $\forall x\varphi(x)$ and hence the fusion of verifiers for $\varphi(a_1), \varphi(a_2), \ldots$ need not be a verifier for $\forall x\varphi(x)$ (this is a familiar problem, going back to Russell, 1918/1919, pp. 236–237, and the early days of logical atomism).

There are a number of ways in which one might attempt to solve this problem within the present framework. One might drop the requirement that a verifying state should necessitate the statement that it verifies, for example, or one might treat the universal statement $\forall x\varphi(x)$ as equivalent, in effect, to $\Pi\, x(\neg Ex \vee \varphi(x))$, where $\Pi\, x$ is an 'outer' quantifier ranging over a fixed domain of all actual and possible individuals and E is an existence predicate – thereby reducing the variable domain case to the fixed domain case. My own favored solution is to suppose that, for each subdomain B of possible individuals, there is a totality state τ_B to the effect that the individuals of B are exactly the individuals that there are. The reader should note that the totality state τ_B is taken to exist even when it is not possible for the individuals of B to be exactly the individuals that there are.[2] The two clauses for the universal quantifier then take the following form:

s ||- $\forall x\varphi(x)$ if there is a subset $B \subseteq A$ composed of the distinct individuals $b_1, b_2, \ldots$ and states $s_1, s_2, \ldots$ such that s_1 ||- $\varphi(b_1)$, s_2 ||- $\varphi(b_2)$, … and $s = \tau_B \sqcup s_1 \sqcup s_2 \sqcup \ldots$;
s -|| $\forall x\varphi(x)$ if there is a subset $B \subseteq A$, an individual b from B, and a state s' such that s' -|| $\varphi(b)$ and $s = \tau_B \sqcup s'$.

And similarly for the existential quantifier.

Another problem is that we have only provided clauses for unrelativized quantification. But one might also want to deal with relativized quantifiers – as in $\forall x(\varphi(x)\colon \psi(x))$ (all φ's ψ) and $\exists x(\varphi(x)\colon \psi(x))$ (some φ's ψ). To take care of this problem, one might relativize the totality condition to the suitably defined content $|\varphi(x)|$ of the restrictor $\varphi(x)$. The clauses for the universal quantifier would then take the following form:

s ||-$\forall x(\varphi(x)\colon \psi(x))$ if there is a subset $B \subseteq A$ composed of the distinct individuals $b_1, b_2, \ldots$ and states $s_1, s_2, \ldots$ such that s_1 ||- $\psi(b_1)$, s_2 ||- $\psi(b_2)$, … and $s = \tau_{|\varphi(x)|,B} \sqcup s_1 \sqcup s_2 \sqcup \ldots$;
s -|| $\forall x(\varphi(x)\colon \psi(x))$ if there is a subset $B \subseteq A$, an individual b from B, and a state s' such that s' -|| $\psi(b)$ and $s = \tau_{|\varphi(x)|,B} \sqcup s'$.

We should note that, on this account, the verifiers for $\forall x(\varphi(x)\colon \psi(x))$ and for $\forall x(\neg\varphi(x) \vee \psi(x))$ will differ, since the first will involve a relativized totality condition $\tau_{|\varphi(x)|,B}$ to the effect that the individuals of B are exactly the individuals that φ, while the second will involve an unrelativized condition τ_B to the effect that the individuals of B are exactly the individuals that there are.

Two variants on the preceding accounts should be briefly noted. First, we have taken a verifier s of $\forall x\varphi(x)$, for example, to be the *fusion* of a totality condition τ_B and the verifiers $s_1, s_2, \ldots$ of the instances of $\forall x\varphi(x)$. But one might think of the totality condition as a precondition for the fusion $s_1 \sqcup s_2 \sqcup \ldots$ of $s_1, s_2, \ldots$ to verify $\forall x\varphi(x)$; and this is a reason for thinking of the verifier s of $\forall x\varphi(x)$, not as the fusion of τ_B and $s_1 \sqcup s_2 \sqcup \ldots$, but as an ordered pair $< \tau_B, s_1 \sqcup s_2 \sqcup \ldots >$, whose first component τ_B is a precondition and whose second component $s_1 \sqcup s_2 \sqcup \ldots$ is a post-condition or verifier proper. It turns out that this way of articulating a verifier into pre- and post-condition is very useful in a number of different contexts (and especially to presupposition).

Second, the verifiers of $\forall x\varphi(x)$ (or $\forall x(\varphi(x)\colon \psi(x))$) have been taken to involve the particular individuals $a_1, a_2, \ldots$ in the range of the quantifier. But it might be thought that $\forall x\varphi(x)$ is verified, in the first place, by certain general facts which, in themselves, do not involve any particular individuals. It turns out that this idea of generic verification can be

developed within the framework of arbitrary objects developed in Fine (1985). Thus the verifier of 'all men are mortal' might be taken to be the generic fact that the arbitrary man is mortal. Although I shall not go into the matter, I believe that the idea of generic verification has a wide range of interesting applications and is especially relevant to problems of 'logical omniscience.'

II Applications

I shall consider five applications in all: two to philosophical logic – the logic of partial content and subject-matter; and three to linguistics – counterfactuals, imperatives, and scalar implicature.

1 The Logic of Partial Content

We have already noted that there appears to be an intuitive sense in which the content of one statement is part of the content of another, for which Q will generally be part of the content of $P \wedge Q$ but $P \vee Q$ will not generally be part of the content of P. In a series of publications dating from 1977, Angell developed a system of 'analytic implication' that was intended to capture the logic of this notion (Angell, 1977; 1989; 2002). It is therefore natural to wonder what the relationship is between his system and our own semantical account of the notion.

It turns out that his system exactly corresponds to our own account, at least under certain very natural assumptions. Let us take $\neg$, $\wedge$, and $\vee$, as before, to be the primitive truth-functional connectives. The notion of the content of A containing the content of B ($A \rightarrow B$) and the notion of the content of A being equivalent to the content of B ($A \leftrightarrow B$) are interdefinable (with $(A \rightarrow B) =_{df} A \wedge B \leftrightarrow A$ and $(A \leftrightarrow B) =_{df} (A \rightarrow B) \wedge (B \rightarrow A)$); and let us, for convenience, take content equivalence ($\leftrightarrow$) rather than content containment $\rightarrow$ as primitive.

Angell's system may then be axiomatized by means of the following axioms and rules:

A1 $A \leftrightarrow \neg\neg A$
A2 $A \leftrightarrow A \wedge A$
A3 $A \wedge B \leftrightarrow B \wedge A$
A4 $(A \wedge B) \wedge C \leftrightarrow A \wedge (B \wedge C)$
A5 $\neg(A \wedge B) \leftrightarrow (\neg A \vee \neg B)$
A6 $\neg(A \vee B) \leftrightarrow (\neg A \wedge \neg B)$
A7 $A \wedge (B \vee C) \leftrightarrow (A \wedge B) \vee (A \wedge C)$
R1 $A(B), B \leftrightarrow C / A(C)$

The sole rule is R1, which allows us to substitute provable equivalents within any given theorem.

We now adopt the inclusive semantics given under §I.6 above and insist that, in any model $\boldsymbol{M} = (S, \sqsubseteq, (\cdot))$, the set of verifiers and the set of falsifiers of any atomic formula should be non-empty and closed under fusion (it can be shown that this requirement will be met by all formulas whatever if it is met by the atomic formulas).

Let us say that A *analytically implies* B in a model $\boldsymbol{M} = (S, \sqsubseteq, (\cdot))$ if (i) every exact verifier of A (in $\boldsymbol{M}$) contains an exact verifier of B and (ii) every exact verifier of B is contained in

an exact verifier of A (in conformity with our previous account of partial content). Now say that the formula A ↔ B *holds in* the model $\boldsymbol{M} = (S, \sqsubseteq, (\cdot))$ if A analytically implies B and B analytically implies A in $\boldsymbol{M}$. Finally, say that the formula A ↔ B is *valid* if it holds in every model. Then under the proposed semantics, we have the following completeness theorem:

> A ↔ B is a theorem of Angell's system iff it is valid under the truthmaker semantics. (Fine, 2015b; other semantics for which Angell's system is complete are given in Correia, 2004, and Ferguson, 2016.)

This result provides some sort of vindication both of Angell's system and of the proposed account of partial content.

2 Subject-Matter

There is an intuitive notion of subject-matter or of what a statement is about. This notion may have a different focus in different contexts. Thus it may be objectual and concern the objects talked about or it may be predicational and concern what is said about them. Our concern here will be with what one might call 'factual' focus, with what it is in the world that bears upon the statement being true or false.

A standard account of subject-matter, in more or less this sense, was developed by Lewis (1988) and subsequently elaborated by Yablo (2014, ch. 2). A subject-matter, for Lewis, is given by an equivalence relation on worlds where, intuitively, two worlds will stand in the equivalence relation when they do not differ with regard to the subject-matter. Thus if the subject-matter is the current weather in New York, then two worlds will stand in the associated equivalence relation when they do not differ with regard to the current state of the weather in New York.

Lewis has difficulty in defining *the* subject-matter of a statement. Yablo provides a more refined account of subject-matter in terms of truthmakers which removes this difficulty. But he still identifies a subject-matter with a relation on worlds, the subject-matter of a statement now being the similarity relation which holds between two worlds when they share a truthmaker.

There is, I believe, a much more satisfactory and straightforward way of defining subject-matter within the truthmaker framework statement in which no reference is made to worlds or the like (in line with our general unworldly philosophy). Suppose that the verifiers of the statement A are s_1, s_2, …. We may then identify the subject-matter of A with the fusion $\boldsymbol{s} = s_1 \sqcup s_2 \sqcup \ldots$ of its verifiers. After all, it is these states that most directly bear upon the truth of the statement.[3]

It might be thought that this approach to subject-matter is doomed from the start. For consider the statement 'it does or does not rain' and the statement 'it does or does not snow.' Intuitively, their subject-matter is quite different, one concerning the presence or absence of rain and the other the presence or absence of snow. But on our account, the subject-matter of the first statement is the fusion of the presence and absence of rain, let us say, while the subject-matter of the second statement is the fusion of the presence and absence of snow. But these are both impossible states and therefore the same.

But this line of reasoning rests upon adopting the standard coarse-grained conception of impossible states. There is nothing in the truthmaker approach as such which requires us to adopt such a coarse-grained view. Indeed, the more natural view is one in which different

impossible states can be distinguished in terms of the possible states from which they have been obtained (Fine, 2015a); and, in this case, the fine grain of a given subject-matter can be recovered even though its various components have been lumped together into a single impossible state. This then is another case in which impossible states are able to earn their keep.[4]

This account of subject-matter gives rise to a simple and elegant theory of the subject. Since subject-matters are states, we can give an account of the mereology of subject-matters (subject-matter containment, overlap, disjointness, etc.) directly in terms of the mereology of states. We can give a simple account of the subject-matter of complex statements in terms of the subject-matters of their components. Thus where $\sigma(\mathrm{A})$ is the subject-matter of A, we can set:

$$\sigma(\mathrm{A} \wedge \mathrm{B}) = \sigma(\mathrm{A} \vee \mathrm{B}) = \sigma(\mathrm{A}) \sqcup \sigma(\mathrm{B})$$

We can also give a simple account of the *restriction of* a given proposition to some subject-matter $\boldsymbol{s}$. For given two states s and t, let $s \sqcap t$ be their *intersection* (i.e., the fusion of all states that are a common part of s and t). We might then identify the *restriction of* the proposition $P = \{p_1, p_2, \ldots\}$ *to* the subject-matter $\boldsymbol{s}$ to be the proposition $\{p_1 \sqcap \boldsymbol{s}, p_2 \sqcap \boldsymbol{s}, \ldots\}$, obtained by restricting the verifiers of P to the given subject-matter $\boldsymbol{s}$.

Subject-matter will also play a pervasive role in the rest of the theory of truthmakers. Let me give one example from the account of partial content discussed above. When a proposition $P = \{p_1, p_2, \ldots\}$ is closed under fusion, then its subject-matter $\boldsymbol{p} = p_1 \sqcup p_2 \sqcup \ldots$ will itself be a verifier of P. This means that the second clause in the definition of partial content, *viz.* that every verifier of Q should be contained in a verifier of P, can be replaced by the condition that the subject-matter $\boldsymbol{q}$ of Q should be part of the subject-matter $\boldsymbol{p}$ of P.

3 *Counterfactuals*

Ever since the pioneering work of Stalnaker (1968) and Lewis (1973), it has been customary to provide a semantics for counterfactuals statements in terms of possible worlds. The idea, roughly speaking, is to take the counterfactual from A to C to be true just in case the closest world – or all closest worlds, or all sufficiently close worlds – in which A is true is a world – or are worlds – in which C is true. If we introduce a comparative closeness relation $u \preccurlyeq_w v$ (u is as close to w as v), then we may state the third of these options, somewhat more formally, as:

$w \Vdash \mathrm{A} > \mathrm{C}$ if for some world v, $v \Vdash \mathrm{A}$ and, for any world u, $u \Vdash \mathrm{C}$ whenever $u \preceq_w v$ and $u \Vdash \mathrm{A}$.

One familiar difficulty with this account is that it does not enable us to distinguish between the counterfactual 'if Sue were to take the pill then she would live' from the counterfactual 'if Sue were to take the pill or to take the pill and the cyanide then she would live,' even though the first might well be true while the second is false. For the antecedents, 'Sue takes the pill' (p) and 'Sue takes the pill or takes the pill and the cyanide' ($\mathrm{p} \vee (\mathrm{p} \wedge \mathrm{q})$), are truth-functionally equivalent. Indeed, this difficulty is merely the tip of an iceberg. For it can be shown that the possible worlds approach (or any approach that endorses the substitution of truth-functionally equivalent antecedents) is incompatible with our

intuitive judgments about certain scenarios and certain commonly accepted principles of counterfactual reasoning (Fine, 2012b).

In any case, it is worth seeing to what extent these difficulties can be avoided under an alternative approach; and it is here that truthmaker semantics comes into its own. Instead of working with the closeness relation $u \preccurlyeq_w v$ on worlds u, v, and w, we work with a transition relation $t \rightarrow_w u$ on states t and u and world w. Intuitively, $t \rightarrow_w u$ says that u is a possible outcome of imposing t on w. The clause for the truth of a counterfactual at a given world w is then given by:

$w \Vdash A > C$ if for any states t and u for which $t \Vdash A$ and $t \rightarrow_w u$, $u \Vdash C$.[5]

A counterfactual will be true if any exact verifier for the antecedent must transition to an inexact verifier for the consequent. So, for example, the counterfactual 'if the match were struck it would light' will be true because all of the possible outcomes of an exact verifier of 'the match is struck' will be ones which contain an exact verifier for 'the match lights.'

Let us note that this immediately takes care of the Sue example above. Indeed, each of $A > C$ and $B > C$ will be a consequence of $A \vee B > C$ (the so-called rule of Simplification), since the exact verifiers of A and the exact verifies of B are among the exact verifiers of $A \vee B$. So 'if Sue were to take the pill and the cyanide then she would live' will be a consequence of 'if Sue were to take the pill or the pill and cyanide then she would live,' but not of 'If Sue were to take the pill she would live.'

4 *Imperatives*

There seems to be a sense in which one imperative statement may follow from others. Suppose someone says, 'Turn on the light and open the door.' Then it seems that an interlocutor can legitimately say, 'So, turn on the light,' thereby indicating that the one imperative follows from the other. This then raises the question: What is the logic of imperatives? When does one imperative follow from others?

The natural answer to this question is that an imperative inference will be valid just in case the corresponding indicative imperative inference is valid: the imperative Y will follow from the imperatives $X_1, X_2, \ldots, X_n$ just in case the indicative B corresponding to Y follows from the indicatives $A_1, A_2, \ldots, A_n$ corresponding to $X_1, X_2, \ldots, X_n$. Thus in the case above, 'Turn on the light' will follow from 'Turn on the light and shut the door' because 'You turn on the light' follows from 'You turn on the light and shut the door.'

However, this solution does not appear to give the right result in other cases. From 'You turn on the light' follows 'You turn on the light or burn the building down.' But from the imperative 'Turn on the light,' it does not seem as if one can infer 'Turn on the light or burn the building down.' This is Ross's famous paradox.

How then should the semantics and logic of imperatives proceed? Again, it looks as if the framework of truthmaker semantics can provide an answer (Stelzner, 1992; van Rooij, 2000; Aloni and Ciardelli, 2013). Before, we took states to exactly verify or falsify an indicative statement. In the same way, we may take an action (which is a particular kind of state) to be in *exact compliance with* or *exact contravention to* an imperative statement. Thus just as your shutting the door exactly verifies the indicative statement 'You shut the door,' while your shutting the door and turning on the light does not, so your shutting the door is in exact compliance with the imperative statement 'Shut the door,' while your shutting the door and turning on the light is not.

We can then provide compliance and contravention conditions for logically complex imperatives that are the analogue of the verification and falsification conditions for logically complex indicatives. So, for example, we may say:

> the action α is in exact compliance with the conjunctive imperative $X \wedge Y$ iff it is the fusion $\beta \sqcup \gamma$ of an action β that is in exact compliance with X and an action γ that is in exact compliance with Y.

Let the content of an imperative X be the set of actions in exact compliance with the imperative. It may now be suggested that the imperative Y follows from the imperative X just in case the content of Y is part of the content of X. Thus Y will follow from X if (i) any action in compliance with X contains an action in compliance with Y and (ii) any action in compliance with Y will be part of an action in compliance with X. Y must, in this sense, be a necessary means to X.

This account of imperative consequence immediately dissolves Ross's paradox, since the content of $X \vee Y$ will not in general be part of the content of X; and it points to a surprising and intimate connection between the logic of imperatives and the logic of analytic implication.

5 Scalar Implicature

There is a phenomenon that has been discussed in the linguistics literature under the heading 'scalar implicature.' Here is a typical example. Suppose I assert:

(1) John had toast or cereal for breakfast.

Then this is thought to have the 'implicature':

(2) John did not have both toast and cereal for breakfast.

Similarly,

(3) John took one of the candies.

is thought to have the implicature:

(4) John took at most one of the candies.

It has been supposed that, in the first of these cases, there is a sense in which (1) implies (2), since if you believe that John had both toast and cereal then it appears appropriate to register your disagreement with the words:

(5) No (well, in fact), he had both.

But it has also been supposed that the implication is not a regular semantic implication because I can consistently assert:

(6) John had toast or cereal for breakfast and perhaps he even had both.

And likewise in the second case.

How then to account for the implication when it is not a semantic implication? Many philosophers and linguists have appealed to Grice's maxims of cooperative conversation. The rough idea is that if it had been true that John had both toast and cereal for breakfast then I would have said so; and so, from my merely making the weaker claim, you can infer that he did not in fact have both.

However, the Gricean account has a hard time with such examples as:

(1)′ John had toast or cereal or toast and cereal for breakfast; and
(3)′ John took at least one of the candies.

For these do not have the same implicatures – (2) and (4) – as (1) and (3); and yet the same Gricean reasoning would appear to apply.

Let me briefly suggest how these and other difficulties can be avoided under the truthmaker approach, though it will, of course, be necessary to slide over many issues.[6] We suppose that any statement is made against the background of some relevant subject-matter $\boldsymbol{s}$ (again, subject-matter comes into the picture!). Thus if I say that John had toast or cereal for breakfast, we may take the relevant subject-matter to be what he had for breakfast, which we identify with the fusion of various states – his having toast, his having cereal, his having bacon and eggs, and so on.

Any subject-matter $\boldsymbol{s}$ will have an actual part $\boldsymbol{s}_{@}$, which is the fusion of all those parts of $\boldsymbol{s}$ that are actual. Where $\boldsymbol{s}$ is the relevant subject-matter of a statement A, we may now say that A is *exactly true* if $\boldsymbol{s}_{@}$ is an exact verifier of A. We might call $\boldsymbol{s}_{@}$, when $\boldsymbol{s}$ is the relevant subject-matter, the *relevant situation*. Then for A to be exactly true is for it to be exactly verified by the relevant situation.

We make the following key hypothesis:

> The Origin of Scalar Implicature (OSI): Scalar implicature arises from the presupposition that a statement is not merely true but exactly true.

What we say should, in this sense, fit the facts. Let us now see how this hypothesis can take care of the difficulties mentioned above. Consider (1). If John had both cereal and toast for breakfast, then the relevant situation would involve his having both for breakfast and so would not be an exact verifier of (1). Thus the exact truth of (1) requires that John not have both cereal and toast for breakfast. Similarly for (3). If John took more than one candy, then the relevant situation would involve his taking several candies and so would not be an exact verifier of (3) (which should be the verifier of a single instance of (3)). Thus the exact truth of (3) requires that John take a single candy.

Contrast this now with (1)′ and (3)′. In this case, John having both cereal and toast would be an exact verifier of (1)′ and so the exact truth of (1)′ does not require the truth of (2). Similarly for (3)′. For in this case, we may suppose that John taking several candies is an exact verifier for (3)′ (in line with the inclusive semantics for the existential quantifier in §I7) and so again the implicature will be lost.

In this chapter, I have provided the merest sketch of the truthmaker approach. The abstract theory may be developed in many other directions and many other examples of its application might be given: to ground (Correia, 2010; Fine, 2012d; 2015c), the determinate/determinable distinction (Fine, 2011), and the status of impossible states (Fine, 2015a)

within metaphysics; to modal and deontic logic, intuitionistic logic (Fine, 2014a), and the theory of logical remainder and common content (Fine, 2015c; Yablo, 2014, ch. 8) within philosophical logic; to quantification, anaphora, free choice disjunction, intensional descriptions (Moltmann, 2017), cases-constructions (Moltmann, 2015), adverbial modification (van Fraassen, 1973; Hwang and Schubert, 1993), presupposition (Yablo, 2014, ch. 10), the logic and semantics of questions (Ciardelli, Groenendijk, and Roelefson, 2013), and vagueness (van Rooij, 2013) within the philosophy of language and linguistics; to belief revision and closure principles for knowledge and belief (Yablo, 2014, ch. 7) within epistemology; to verisimilitude (Fine, 2015e; Gemes, 2007; Yablo, 2014, §6.7), confirmation (Gemes, 1994; 1997; Yablo, 2014, §§6.1–6.5), and causal modeling within the philosophy of science; and to the psychology of reasoning (Koralus and Mascarenhas, 2013) and the frame problem within cognitive science. But I hope I have said enough to give the reader a taste of what the theory is like, of what it is capable of doing, and of how, in many respects, it is far superior to the more usual approach in terms of possible worlds.

Notes

1 One might also provide a truthmaker semantics for *intuitionistic* sentential logic (Fine, 2014a) and, in this case, it is not necessary to state separate clauses for the verification and falsification of an arbitrary statement.

2 Allowing impossible totality states of this sort greatly simplifies the semantics and is another example of the benefits to be gained by admitting impossible states.

3 Fine (2015d). Strictly speaking, s is the *positive* subject-matter of A. The *negative* subject-matter may be taken to be $t = t_1 \sqcup t_2 \sqcup \ldots$, where t_1, t_2, … are the falsifiers of A; and the *overall* subject-matter may be taken to be (s, t) or $s \sqcup t$.

4 A further case is the truthmaker semantics for intuitionistic logic in Fine (2014a), which also makes use of a rich ontology of impossible states.

5 Fine (2012c). We may also give the following more complicated clause for the exact verification of a counterfactual:

$s \Vdash A > C$ iff (i) for each t for which $t \Vdash A$ there is an s_t and a u for which $t \rightarrow s_t\, u$,
(ii) for any state t for which $t \Vdash A$ and any state u for which $t \rightarrow s_t\, u$, $u \Vdash > C$,
(iii) s is the fusion of $\{s_t\colon t \Vdash A\}$;

and give a related clause for the exact falsification of a counterfactual.

6 I first publicly presented a solution along these lines in the Jack Smart lecture of 2010; and a similar solution has been independently proposed by Robert van Rooij in his (2013) and in some recent unpublished work.

Analyticity

PAUL ARTIN BOGHOSSIAN

I

This is what many philosophers believe today about the analytic/synthetic distinction: In his classic early writings on analyticity – in particular, in "Truth by convention" (1976a), "Two dogmas of empiricism" (1953), and "Carnap and logical truth" (1976b) – Quine showed that there can be no distinction between sentences that are true purely by virtue of their meaning, and those that aren't. In so doing, Quine devastated the philosophical programs that depend upon a notion of analyticity – specifically, the linguistic theory of necessary truth, and the analytic theory of *a priori* knowledge.

Quine himself, so the story continues, went on to espouse far more radical views about meaning, including such theses as meaning-indeterminacy and meaning-skepticism. However, it is not necessary, and certainly not appealing, to follow him on this trajectory. As realists about meaning, we may treat Quine's self-contained discussion in the early papers as the basis for a profound *insight* into the nature of meaning-facts, rather than for any sort of rejection of them. We may discard the notions of the analytic and the *a priori* without thereby buying in on any sort of unpalatable skepticism about meaning.

Now, I don't know precisely how many philosophers believe all of the above, but I think it would be fair to say that it is the prevailing view. Philosophers with radically differing commitments – including radically differing commitments about the nature of meaning itself – subscribe to it: whatever precisely the correct construal of meaning, so they seem to think, Quine has shown that it will not sustain a distinction between the analytic and the synthetic. Here, merely for purposes of illustration, are two representative endorsements of the view, both of them also containing helpful references to its popularity. The first is by Bill Lycan.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

> It has been nearly forty years since the publication of "Two Dogmas of Empiricism." Despite some vigorous rebuttals during that period, Quine's rejection of analyticity still prevails – in that philosophers *en masse* have either joined Quine in repudiating the "analytic/synthetic" distinction or remained (however mutinously) silent and made no claims of analyticity.
>
> This comprehensive capitulation is somewhat surprising, in light of the radical nature of Quine's views on linguistic meaning generally. In particular, I doubt that many philosophers accept his doctrine of the indeterminacy of translation.

Lycan goes on to promise that, in his paper, he is going to

> make a Quinean case against analyticity, without relying on the indeterminacy doctrine. For I join the majority in denying both analyticity and indeterminacy. (Lycan, 1991, p. 111)

Next, here are two other committed realists about meaning, Jerry Fodor and Ernie Lepore, talking about a thesis that, they say,

> practically everybody thinks that there are good reasons to endorse;… [namely]… that there aren't any expressions that are true or false solely in virtue of what they mean. (Fodor and Lepore, 1991a, p. 332)

Fodor and Lepore go on to claim that this result clearly undermines the idea of a belief or inference that is warranted *a priori*.

Now, my disagreement with the prevailing view is not total. There is *a* notion of 'truth by virtue of meaning' – what I shall call the metaphysical notion – that *is* undermined by a set of indeterminacy-independent considerations. Since this notion is presupposed by the linguistic theory of necessity, that project fails and must be abandoned.

However, I disagree with the prevailing view's assumption that those very same considerations also undermine the analytic explanation of the *a priori*. For I believe that an entirely distinct notion of analyticity underlies that explanation, a notion that is epistemic in character. And in contrast with the metaphysical notion, the epistemic notion can be defended, I believe, provided that even a minimal realism about meaning is true. I'm inclined to hold, therefore, that there can be no effective Quinean critique of the *a priori* that does not ultimately depend on Quine's radical thesis of the indeterminacy of meaning, a thesis that, as I've stressed, many philosophers continue to reject.

All of this is what I propose to argue in this chapter. I should emphasize right at the outset, however, that I am not a historian, and my interest here is not historical. Think of me, rather, as asking, on behalf of all those who continue to reject Quine's later skepticism about meaning: Can something like the analytic explanation of the *a priori* be salvaged from the wreckage of the linguistic theory of necessity?

Belief, Apriority, and Indeterminacy

We need to begin with some understanding, however brief and informal, of what it is to believe something, and of what it is for a belief to count as *a priori* knowledge.

In my view, the most plausible account of the matter is that believing is a relation to a proposition in the technical sense: a mind-independent, language-independent abstract

object that has its truth-conditions essentially. Against this background, a belief is true just in case its proposition is true.

However, I don't want to presuppose such a picture of belief in the present context. Not that there would be anything particularly wrong or question-begging about doing so; as Quine himself has made clear, his rejection of propositions is supposed to rest on his critique of analyticity, not the other way around.[1] Nevertheless, in the interests of keeping potential distractions to a minimum, I will work with a picture of belief that is far more hospitable to Quine's basic outlook.

According to this more 'linguistic' picture, the objects of belief are not propositions, but rather interpreted sentences: for a person T to believe that p is for T to hold true a sentence S which means that p in T's idiolect.[2]

Against this rough and ready background, we may say that for T to know that p is for T to justifiably hold S true, with a strength sufficient for knowledge, and for S to be true. And to say that T knows p *a priori* is to say that T's warrant for holding S true is independent of outer, sensory experience.[3] The interesting question in the analysis of the concept of apriority concerns this notion of warrant: What is it for a belief to be justified, independently of outer sensory experience?

On a minimalist reading, to say that the warrant for a given belief is *a priori* is just to say that it is justified, with a strength sufficient for knowledge, without appeal to empirical evidence.[4] On a stronger reading, it is to say that, and to say in addition that the justification in question is not defeasible by any future empirical evidence.[5] Which of these two notions is at issue in the present debate?

My own view is that the minimal notion forms the core of the idea of apriority. However, in this chapter I will aim to provide the materials with which to substantiate the claim that, under the appropriate circumstances, the notion of analyticity can help explain how we might have *a priori* knowledge even in the strong sense. A defense of the strong notion is particularly relevant in the present context, for Quine seems to have been particularly skeptical of the idea of empirical indefeasibility.

Before proceeding, we should also touch briefly on the notion of meaning-indeterminacy. In chapter 2 of *Word and Object* Quine (1960) argued that, for any language, it is possible to find two incompatible translation manuals that nevertheless perfectly conform to the totality of the evidence that constrains translation. This is the famous doctrine of the indeterminacy of translation. Since Quine was, furthermore, prepared to assume that there could not be facts about meaning that are not captured in the constraints on best translation, he concluded that meaning-facts themselves are indeterminate – that there is, strictly speaking, no determinate fact of the matter as to what a given expression in a language means. This is the doctrine that I have called the thesis of the indeterminacy of meaning.

An *acceptance* of meaning-indeterminacy can lead to a variety of *other* views about meaning. For instance, it might lead to an outright eliminativism about meaning. Or it might be taken as a reason to base the theory of meaning on the notion of likeness of meaning, rather than on that of sameness of meaning (see Harman, 1973). In this chapter I am not concerned with the question of what moral should be drawn from the indeterminacy thesis, on the assumption that it is true; nor am I concerned with whether the indeterminacy thesis is true. I am only concerned to show that a skepticism about epistemic analyticity cannot stop short of the indeterminacy thesis, a thesis that, as I have stressed, most philosophers agree in rejecting (see Chapter 26, INDETERMINACY OF TRANSLATION).

Analyticity: Metaphysical or Epistemological?

Traditionally, three classes of statements have been thought to be the objects of *a priori* knowledge: logical statements, exemplified by such truths as:

Either Brutus killed Caesar or he did not;

mathematical statements, such as:

$7 + 5 = 12$;

and conceptual truths, for instance:

All bachelors are unmarried.

The problem has always been to explain how any statement could be known *a priori*. After all, if a statement is known *a priori*, then it must be true. And if it is true, then it must be factual, capable of being true or false. What could possibly entitle us to hold a factual sentence true on *a priori* grounds?

The history of philosophy has known a number of answers to this question, among which the following has had considerable influence: We are equipped with a special evidence-gathering faculty of *intuition*, distinct from the standard five senses, which allows us to arrive at justified beliefs about the necessary properties of the world. By exercising this faculty, we are able to know *a priori* such truths as those of mathematics and logic.

The central impetus behind the *analytic* explanation of the *a priori* is the desire to explain the possibility of *a priori* knowledge without having to postulate such a special faculty, one that has never been described in satisfactory terms. The question is: How could a factual statement S be known *a priori* by T, without the help of a special evidence-gathering faculty?

Here, it would seem, is one way: *If mere grasp of* S*'s meaning by* T *sufficed for* T*'s being justified in holding* S *true.* If S were analytic in this sense, then, clearly, its apriority would be explainable without appeal to a special faculty of intuition: mere grasp of its meaning by T would suffice for explaining T's justification for holding S true. On this understanding, then, 'analyticity' is an overtly *epistemological* notion: a statement is 'true by virtue of its meaning' provided that grasp of its meaning alone suffices for justified belief in its truth.

Another, far more metaphysical, reading of the phrase 'true by virtue of meaning' is also available, however, according to which a statement is analytic provided that, in some appropriate sense, it *owes its truth-value completely to its meaning*, and not at all to 'the facts.'

Which of these two possible notions has been at stake in the dispute over analyticity? There has been a serious unclarity on the matter. Quine himself tends to label the doctrine of analyticity an epistemological one, as, for example, in the following passage from "Carnap and logical truth":

> the linguistic doctrine of logical truth, which is an epistemological doctrine, goes on to say that logical truths are true purely by virtue of the intended meanings, or intended usage, of the logical words. (Quine, 1976b, p. 103)

However, his most biting criticisms seem often to be directed at what I have called the metaphysical notion. Consider, for example, the object of disapproval in the following famous passage, a passage that concludes the discussion of analyticity in "Two dogmas":

> It is obvious that truth in general depends on both language and extralinguistic fact. The statement 'Brutus killed Caesar' would be false if the world had been different in certain ways, but it would also be false if the word 'killed' happened rather to have the sense of 'begat.' Thus one is tempted to suppose in general that the truth of a statement is somehow analyzable into a linguistic component and a factual component. Given this supposition it next seems reasonable that in some statements the factual component should be null; and these are the analytic statements. But for all its a priori reasonableness, a boundary between analytic and synthetic statements simply has not been drawn. That there is such a distinction to be drawn at all is an unempirical dogma of empiricists, a metaphysical article of faith. (Quine, 1953, pp. 36–37)

Now, I think that there is no doubt that many of the proponents of the analytic theory of the *a priori*, among them especially its positivist proponents, intended the notion of analyticity to be understood in this metaphysical sense; very shortly I shall look at why.

Before doing that, however, I want to register my wholehearted agreement with Quine, that the metaphysical notion is of dubious explanatory value, and possibly also of dubious coherence. I believe that Quine's discrediting of this idea constitutes one of his most enduring contributions to philosophy. Fortunately for the analytic theory of the *a priori*, it can be shown that it need have nothing to do with the discredited idea.

The Metaphysical Concept

What could it possibly mean to say that the truth of a statement is fixed exclusively by its meaning and not by the facts? Isn't it in general true – indeed, isn't it in general a truism – that for any statement S,

> S is true iff for some p, S means that p and p?

How could the *mere* fact that S means that p make it the case that S is true? Doesn't it also have to be the case that p? As Harman has usefully put it (he is discussing the sentence 'Copper is copper'):

> what is to prevent us from saying that the truth expressed by "Copper is copper" depends in part on a general feature of the way the world is, namely that everything is self-identical. (Harman, 1968, p. 128)[6]

The proponent of the metaphysical notion does have a comeback, one that has perhaps not been sufficiently addressed. If he is wise, he won't want to deny the meaning-truth truism. What he will want to say instead is that, in some appropriate sense, our meaning p by S *makes it the case that p*.

But this line is itself fraught with difficulty. For how can we make sense of the idea that something is made true by our meaning something by a sentence?

Consider the sentence 'Either p or not p.' It is easy, of course, to understand how the fact that we mean what we do by the ingredient terms fixes what is expressed by the sentence as

a whole; and it is easy to understand, in consequence, how the fact that we mean what we do by the sentence determines whether the sentence expresses something true or false. But as Quine points out, that is just the normal dependence of truth on meaning. What is far more mysterious is the claim that the *truth of what the sentence expresses* depends on the fact that it is expressed by that sentence, so that we can say that what is expressed wouldn't have been true at all, had it not been for the fact that it is expressed by that sentence. There are at least two insurmountable problems in making sense of this idea.

First, any such account would make the truth of what is expressed *contingent*, whereas most of the statements at stake in the present discussion are clearly necessary. Second, such an account would make the truth of the claim expressed contingent *on* an act of meaning, and that is very peculiar. Putting aside the question whether it is so much as intelligible, what plausibility could it conceivably have? Are we to suppose that, prior to our stipulating a meaning for the sentence

Either snow is white or it isn't

it wasn't the case that either snow was white or it wasn't? Isn't it overwhelmingly obvious that this claim was true *before* such an act of meaning, and that it would have been true even if no one had thought about it, or chosen it to be expressed by one of our sentences?

Why, if this idea is as problematic as I, following Quine, have claimed it to be, did it figure so prominently in positivist thinking about analyticity?

Part of the answer derives from the fact that the positivists didn't merely want a theory of *a priori* knowledge; they also wanted a reductive theory of necessity. The motivation was not purely epistemological, but metaphysical as well. Guided by the fear that objective, language-independent, necessary connections would be metaphysically odd, they attempted to show that all necessities could be understood to consist in linguistic necessities, in the shadows cast by conventional decisions concerning the meanings of words. Linguistic meaning, by itself, was supposed to generate necessary truth; *a fortiori*, linguistic meaning, by itself, was supposed to generate truth. Hence the play with the metaphysical concept of analyticity.

But this is, I believe, a futile project. In general, I have no idea what would constitute a better answer to the question: 'What is responsible for generating the truth of a given class of statements?' than something bland like 'the world' or 'the facts'; and, for reasons that I have just been outlining, I cannot see how a good answer might be framed in terms of meaning in particular.

So I have no sympathy with the linguistic theory of necessity or with its attendant Conventionalism. Unfortunately, the impression appears to be widespread that there is no way to disentangle that view from the analytic theory of the *a priori*; or, at a minimum, that there is no way to embrace the epistemic concept of analyticity without also embracing its metaphysical counterpart. I don't know whether Harman believes something of the sort; he certainly gives the impression of doing so in his frequent suggestions that anyone deploying the notion of analyticity would have to be deploying both of its available readings simultaneously:

> It turned out that someone could be taught to make the analytic-synthetic distinction only by being taught a rather substantial theory, a theory including such principles as that meaning can make something true and that knowledge of meaning can give knowledge of truth. (Harman, 1994a, p. 47; see also Harman, 1968)

One of the main points of the present chapter is that these two notions of analyticity are distinct, and that the analytic theory of the *a priori* needs only the epistemological notion and has no use whatsoever for the metaphysical one. We can have an analytic theory of the *a priori* without in any way subscribing to a Conventionalism about anything. It is with the extended defense of this claim that much of the present chapter is concerned.

The Epistemological Concept

Turning, then, to the epistemological notion of analyticity, we immediately confront a serious puzzle: How could any sentence be analytic in this sense? How could mere grasp of a sentence's meaning justify someone in holding it true?

Clearly, the answer to this question has to be *semantical*: something about the sentence's meaning, or about the way that meaning is fixed, must explain how its truth is knowable in this special way. What could this explanation be?

In the history of the subject, two different sorts of explanation have been especially important. Although these, too, have often been conflated, it is crucial to distinguish between them.

One idea was first formulated in full generality by Gottlob Frege. According to Frege, a statement's analyticity (in my epistemological sense) is to be explained by the fact that it is *transformable into a logical truth by the substitution of synonyms for synonyms*. When a statement satisfies this semantical condition, I shall say that it is 'Frege-analytic.'[7]

Now, it should be obvious that Frege-analyticity is at best an *incomplete* explanation of a statement's epistemic analyticity and, hence, of its apriority. For suppose that a given sentence S is Frege-analytic. How might this fact explain its analyticity? Clearly, two further assumptions are needed. First, that facts about synonymy are knowable *a priori*; and second, that so are the truths of logic. Under the terms of these further assumptions, a satisfying explanation goes through. Given its Frege-analyticity, S is transformable into a logical truth by the substitution of synonyms for synonyms. Facts about synonymy are *a priori*, so it's *a priori* that S is so transformable. Furthermore, the sentence into which it is transformable is one whose truth is itself knowable *a priori*. Hence, S's truth is knowable *a priori*.

Frege tended not to worry about these further assumptions for two reasons. First, he thought it obviously constitutive of the idea of meaning that meaning is transparent – that any competent user of two words would have to be able to know *a priori* whether or not they meant the same. Second, he also thought it obvious that there could be no substantive epistemology for logic – *a fortiori*, not one that could explain its apriority. As a consequence, he was happy to take logic's apriority for granted. For both of these reasons, he didn't worry about the fact that the concept of Frege-analyticity simply leaned on these further assumptions without explaining them.

I think the jury is still out on whether Frege was right to take these further assumptions for granted. There is certainly a very strong case to be made for the transparency of meaning.[8] And there are well-known difficulties providing a substantive epistemology for something as basic as logic, difficulties we shall have occasion to further review below. Nevertheless, because we cannot simply assume that Frege was right, we have to ask how a complete theory of the *a priori* would go about filling in the gaps left by the concept of Frege-analyticity.

I shall have very little to say about the first gap. The question whether facts about the sameness and difference of meaning are *a priori* cannot be discussed independently of the question of what meaning is, and that is not an issue that I want to prejudge in the present context. On some views of meaning – for example, on certain conceptual-role views – the apriority of synonymy is simply a by-product of the very nature of meaning-facts, so that no substantive epistemology for synonymy is necessary or, indeed, possible. On other views – for example, on most externalist views of meaning – synonymy is not *a priori*, so there is no question of a sentence's Frege-analyticity fully explaining its epistemic analyticity.

Since this issue about the apriority of synonymy turns on questions that are currently unresolved, I propose to leave it for now. As we shall see, none of the analyticity-skeptical considerations we shall consider exploit it in any way. (Quine never argues that the trouble with Frege-analyticity is that synonymies are *a posteriori*.)

Putting aside, then, skepticism about the apriority of synonymy, and, for the moment anyway, skepticism about the very existence of Frege-analytic sentences, let us ask quite generally: What class of *a priori* statement would an account based on the notion of Frege-analyticity *fail* to explain?

Two classes come to mind. On the one hand, *a priori* statements that are not transformable into logical truths by the substitution of synonyms for synonyms; and, on the other, *a priori* statements that are trivially so transformable.

Taking the first class first, there does appear to be a significant number of *a priori* statements that are not Frege-analytic. For example:

Whatever is red all over is not blue.
Whatever is colored is extended.
If x is warmer than y, then y is not warmer than x.

These statements appear not to be transformable into logical truths by the appropriate substitutions: the ingredient descriptive terms seem not to be decomposable in the appropriate way.

The second class of recalcitrant statements consists precisely of the truths of logic. The truths of logic satisfy, of course, the conditions on Frege-analyticity: but they satisfy them trivially. And it seems obvious that we can't hope to explain our entitlement to belief in the truths of logic by appealing to their analyticity in this sense: knowledge of Frege-analyticity presupposes knowledge of logical truth, and so can't explain it.

How, then, is the epistemic analyticity of these recalcitrant truths to be explained? As we shall see below, the Carnap/Wittgenstein solution turned on the suggestion that they are to be viewed as *implicit definitions* of their ingredient terms. When a statement satisfies this semantical condition, I shall sometimes say that it is 'Carnap-analytic.' However, before proceeding to a discussion of Carnap-analyticity I want to re-examine Quine's famous rejection of the much weaker concept of Frege-analyticity.

II

"Two Dogmas" and the Rejection of Frege-Analyticity

For all its apparent limitations, the concept of Frege-analyticity is not without interest. Even though Quine made it fashionable to claim otherwise, "All bachelors are male" *does* seem to be transformable into a logical truth by the substitution of synonyms for synonyms, and

that fact *does* seem to have something important to do with that statement's apriority. If, then, appearances are not misleading here, and a significant range of *a priori* statements are Frege-analytic, then the problem of their apriority is *reduced* to that of the apriority of logic and synonymy and, in this way, a significant economy in explanatory burden is achieved.

It was, therefore, an important threat to the analytic theory of the *a priori* to find Quine arguing, in one of the most celebrated articles of the twentieth century, that the apriority of no sentence could be explained by appeal to its Frege-analyticity, because no sentence of a natural language could *be* Frege-analytic.

It has not been sufficiently appreciated, it seems to me, that "Two dogmas" is *exclusively* concerned with this weaker notion of Frege-analyticity, and not at all with the more demanding project of explaining the apriority of logic. But this is made very clear by Quine:

> Statements which are analytic by general philosophical acclaim are not, indeed, far to seek. They fall into two classes. Those of the first class, which may be called *logically true*, are typified by:
>
> (1) No unmarried man is married.
>
> The relevant feature of this example is that it is not merely true as it stands, but remains true under any and all reinterpretations of 'man' and 'married.' If we suppose a prior inventory of *logical* particles … then in general a logical truth is a statement that remains true under all reinterpretations of its components other than the logical particles.
>
> But there is also a second class of analytic statements, typified by:
>
> (2) No bachelor is married.
>
> The characteristic of such a statement is that it can be turned into a logical truth by putting synonyms for synonyms. (1953, pp. 22–23)

Quine goes on to say very clearly:

> Our problem … is analyticity; and here the major difficulty lies not in the first class of analytic statements, the logical truths, but rather in the second class, which depends on the notion of synonymy. (1953, p. 24)

Most of the rest of "Two dogmas" is devoted to arguing that no good sense can be made of such analyticities of the 'second class.'

None of this would make any sense unless Quine were intending in "Two dogmas" to be restricting himself solely to the notion of Frege-analyticity. Of course, it is the point of two other important papers of his – "Truth by convention" and "Carnap and logical truth" – to argue that there is no non-trivial sense in which *logic* is analytic. We will turn to that issue in due course. Relative to the Fregean notion, however, the logical truths are trivially analytic; and so, given his apparent desire to restrict his attention to that notion in "Two dogmas," he simply concedes their 'analyticity' in the only sense he takes to be under discussion. What he wishes to resist in "Two dogmas," he insists, is merely the claim that there are any *non-trivial instances of Frege-analyticity*.[9]

Skeptical Theses about Analyticity

What form does Quine's resistance take? Let's agree, right away, that the result being advertised isn't anything modest, of the form: There are fewer analyticities than we had previously thought. Or, there are some analytic truths, but they are not important for the

purposes of science. Or anything else of a similar ilk. Rather, as a very large number of Quine's remarks make clear, the sought-after result is something ambitious, to the effect that the notion of Frege-analyticity is, somehow or other, not cogent. The many admirers of "Two dogmas" have been divided on whether to read this as the claim that the notion of Frege-analyticity does not have a well-defined, determinate content, or whether to read it merely as claiming that, although it has an intelligible content, it is necessarily uninstantiated.

I'll call the first claim a *Non-factualism* about analyticity:

> (NF) No coherent, determinate property is expressed by the predicate 'is analytic' (or, since these are correlative terms, the predicate 'is synthetic'); consequently, no coherent proposition is expressed by sentences of the form 'S is analytic' and 'S is synthetic.'

And I'll call the second an *Error Thesis* about analyticity:

> (ET) There is a coherent, determinate property expressed by 'is analytic,' but it is necessarily uninstantiated; consequently, all sentences of the form 'S is analytic' are necessarily false.[10]

Unfortunately, "Two dogmas" doesn't seem to have a clear view about exactly which of these claims it should be read as arguing for.

In favor of the suggestion that Quine's goal is something with the form of a non-factualism about Frege-analyticity there is, first, the fact that the idiom favored by Quine – that there is no distinction between the analytic and the synthetic – sits much better with a non-factualist thesis than it does with an error thesis. The latter claim would be far more happily expressed by saying, "All sentences are necessarily synthetic."

Further, and more importantly, there is the actual character of Quine's *arguments*. As any reader of "Two dogmas" knows, much of that article is given over to arguing that we don't really understand what 'is analytic' means, that previous explications either fail to specify its meaning in sufficiently non-circular – hence sufficiently illuminating – terms, or fail to specify it at all.

For example, against the suggestion that 'analyticity' might be understood via a specification of the 'semantical rules' for a language, Quine remarks:

> Let us suppose … an artificial language L_o whose semantical rules have the form explicitly of a specification, by recursion or otherwise, of all the analytic statements of L_o. The rules tell us that such-and-such statements, and only those, are the analytic statements of L_o. Now here the difficulty is simply that the rules contain the word 'analytic' which we do not understand! We understand what expressions the rules attribute analyticity to, but we do not understand what the rules attribute to these expressions. (Quine, 1953, p. 33)

There are, then, weighty textual reasons for taking Quine to be arguing for something with the form of an NF. Other considerations, however, pull in the opposite direction. The most striking of these occurs in the following passage concerning stipulative definitions, that is, the explicitly conventional introduction of novel notation for the purposes of abbreviation. The passage is framed by a concession on Quine's part that Frege-analyticity would be intelligible, provided the notion of synonymy were. In the case of stipulative definitions, writes Quine,

> the definiendum becomes synonymous with the definiens simply because it has been created expressly for the purpose of being synonymous with the definiens. Here we have a really transparent case of synonymy created by definition; would that all species of synonymy were as intelligible. (Quine, 1953, p. 26)

This admission, however, in the context of Quine's concession, would appear to be utterly inconsistent with NF. For an NF about Frege-analyticity is committed to the claim that there is no coherent, determinate property of synonymy: no conceivable mechanism could generate an instance of synonymy, for there is no coherent property to generate. *A fortiori*, no stipulational mechanism could.

In fact, even the ET, as stated, is inconsistent with the concession. For according to the ET, although there is such a property as analyticity, of necessity no sentence has it. Yet according to the concession, there could be sentences – namely, those built up in appropriate ways out of the expressions implicated in stipulative definitions – that are analytic. So even the ET needs to be modified, if it is to be made consistent with Quine's admission, thus:

> (ET*) There is a coherent property expressed by 'is analytic,' but, with the exception of those instances that are generated by stipulational mechanisms, it is necessarily uninstantiated.

Let me bring the exegetical aspect of this discussion to a premature and artificial close. It is clear that a thesis of either form would result in a philosophically important skepticism about Frege-analyticity. What we need to do is distinguish between the two theses and assess the case that can be made on their behalf.

In actual fact, however, I don't propose to look at Quine's well-known arguments in detail. Instead, my strategy will be to argue that neither a non-factualism about Frege-analyticity, nor an error thesis about it, can plausibly fall short of an outright rejection of meaning itself. Since – along with practically everybody else – I consider such a rejection to be highly implausible, I take this to constitute a *reductio* of Quine's skepticism about Frege-analyticity.

Non-factualism about Frege-Analyticity

Let's begin with the non-factualist rejection of Frege-analyticity. Now, to say that there is no such property as the property of Frege-analyticity is essentially to say that, for *any* sentence, there is no fact of the matter as to whether it is transformable into a logical truth by the substitution of synonyms for synonyms. Presumably, this itself is possible only if either there is no fact of the matter about what counts as a logical truth, or no fact of the matter about when two expressions are synonymous. Since the factuality of logic is not in dispute, the only option is a non-factualism about synonymy.

But, now, how can there fail to be facts about whether any two expressions – even where these are drawn from within a *single* speaker's idiolect – mean the same? Wouldn't this have to entail that there are no facts about what each expression means individually? Putting the question the other way: Could there be a fact of the matter about what each expression means, but no fact of the matter about whether they mean the same?[11]

Let's consider this question first against the background of an unQuinean relational construal of meaning, according to which an expression's meaning something is a relation M between it and its meaning, the meaning C. Someone who held that a non-factualism about synonymy could coexist with a determinacy about meaning would have to hold that, although it might be true that some specific word – say, "cow" – bears some specific relation M to some specific meaning C, there is no fact of the matter about whether some *other* word – some other orthographically identified particular – bears precisely the same relation to precisely the same meaning.

But how could this be? How could it conceivably turn out that it is intelligible and true to say that "cow" bears M to C, and that it is not merely false but *non-factual* to say that some other word – "vache," as it may be – also does? What could be so special about the letters "c," "o," "w"?

The answer, of course, is that there is nothing special about them. If it is factual that one word bears M to C, it is surely factual that some other word does. Especially on a relational construal of meaning, it makes no sense to suppose that a determinacy about meaning could coexist with a non-factualism about synonymy.

The question naturally arises whether this result is forthcoming *only* against the background of a relational construal of meaning. I think it's quite clear that the answer is 'no.' To see why, suppose that instead of construing meaning-facts as involving relations to meanings we construe them thus: "cow" means *cow* just in case "cow" has the monadic property R, a history of use, a disposition, or whatever your favorite candidate may be. Precisely the same arguments go through: it remains equally difficult to see how, given that "cow" has property R, it could fail to be factual whether or not some other word does.

The Error Thesis about Frege-Analyticity

I think, then, that if a plausible skepticism about Frege-analyticity is to be sustained, it cannot take the form of a non-factualism. Does an error thesis fare any better? According to this view, although there are determinate facts about which sentences are transformable into logical truths by the appropriate manipulations of synonymy, this property is necessarily uninstantiated: it is nomically impossible for there to be any Frege-analytic sentences. Our question is: Does at least this form of skepticism about Frege-analyticity avoid collapse into the indeterminacy doctrine?

Well, I suppose that if we are being very strict about it, we may have to admit that it is barely *logically possible* to combine a denial of indeterminacy with an error thesis about synonymy; so that we can say that although there are determinate facts about what means what, it is impossible for any two things to mean the same thing. But is such a view plausible? Do we have any reason for believing it? I think not.

Let's begin with the fact that even Quine has to believe that it is possible for two *tokens of the same orthographic type* to be synonymous, for that much is presupposed by his own account of logical truth. As we saw in the passage I quoted above, Quine describes a truth of logic as:

> a statement [which is true and which] remains true under all reinterpretations of its components other than the logical particles. (Quine, 1953, pp. 22–23)

Clearly, the idea isn't that such a statement will remain true no matter how the non-logical particles are substituted for, but rather that it will remain true provided that the non-logical particles are substituted for in a uniform way, with multiple occurrences of the same word receiving the same substitution in every case. But what should we count as the same here? As Strawson pointed out, it won't do merely to insist that multiple occurrences of a word be replaced by orthographically uniform replacements; for it certainly seems possible to imagine an orthographically uniform way of substituting for the non-logical particles of 'No unmarried man is married' that results in a falsehood: 'No unilluminated book is illuminated.' And it's hard to see how this is to be fixed without making some use of the idea that the orthographically uniform replacements should express the same meaning (Strawson, 1971, p. 117).

So even Quine has to admit – what in any event seems independently compelling – that two tokens of the same type can express the same meaning.

What about two tokens of different types? Here again, our own argument can proceed from Quine's own admissions. As we saw, even Quine has to concede that two expressions can mean the same thing, provided that they are explicitly stipulated to mean the same thing. So the skepticism about synonymy has to boil down to the following, somewhat peculiar claim: Although there is such a thing as the property of synonymy; and although it can be instantiated by pairs of tokens of the same orthographic type; and although it can be instantiated by pairs of tokens of distinct orthographic types, provided that they are related to each other by way of an explicit stipulation; it is, nevertheless, in principle impossible to generate instances of this property in some other way, via some other mechanism. For example, it is impossible that two expressions that were introduced independently of each other into the language should have been introduced with exactly the same meanings.

But what conceivable rationale could there be for such a claim? As far as I am able to tell, there is precisely one argument in the literature that is supposed to provide support for this claim. It may be represented as follows:

> Premise: Meaning is radically holistic in the sense that: "What our words mean depends on *everything* we believe, on *all* the assumptions we are making." (Harman, 1973, p. 14, emphasis in the original)

Therefore,

> Conclusion: It is very unlikely that, in any given language, there will be two words of distinct types that mean exactly the same thing.

I am inclined to agree that this argument (properly spelled out) is valid, and so, that if a radical holism about meaning were true, then synonymies between expressions of different types would be rare.

However, I note that "rare" does not mean the same as "impossible," which is the result we were promised. And, much more importantly, I am completely inclined to disagree that "Two dogmas" provides any sort of cogent argument for meaning holism in the first place.

It's easy to see why, if such a radical meaning holism were true, synonymies might be hard to come by. For although it is not unimaginable, it is unlikely that two words of

distinct types will participate in *all* of the same beliefs and inferences. Presumably there will always be some beliefs that will discriminate between them – beliefs about their respective shapes, for example.

But what reason do we have for believing that *all* of a word's uses are constitutive of its meaning?

Many Quineans seem to hold that the crucial argument for this intuitively implausible view is to be found in the concluding sections of "Two dogmas." In those concluding sections, Quine argues powerfully for the epistemological claim that has come to be known as the Quine–Duhem thesis: confirmation is holistic in that the warrant for any given sentence depends on the warrant for every other sentence. In those concluding sections, Quine also assumes a Verificationist theory of meaning, according to which the meaning of a sentence is fixed by its method of confirmation. Putting these two theses together, one can speedily arrive at the view that a word's meaning depends on *all* of its inferential links to other words, and hence at the thesis of meaning holism.[12]

This, however, is not a very convincing train of thought. First, and not all that importantly, this couldn't have been the argument that *Quine* intended against Frege-analyticity, for this argument for meaning holism is to be found in the very last pages of "Two dogmas," well after the rejection of Frege-analyticity is taken to have been established.

Second, and more importantly, the argument is not very compelling because it depends crucially on a verificationism about meaning, a view that we have every good reason to reject, and which has in fact been rejected by most contemporary philosophers.

Finally, and perhaps most importantly, any such holism-based argument against the possibility of synonymy would need to be supported by something that no one has ever provided – a reason for believing that yielding such an intuitively implausible result about synonymy isn't itself simply a *reductio* of meaning holism[13] (see Chapter 15, HOLISM).

III

The Analyticity of Logic

If the preceding considerations are correct, then there is no principled objection to the existence of Frege-analyticities, and, hence, no principled objection to the existence of statements that are knowable *a priori* if logical truth is.[14]

But what about logical truth? Is it knowable *a priori*? And, if so, how?[15]

In the case of some logical truths, the explanation for how we have come to know them will be clear: we will have deduced them from others. So our question concerns only the most elementary laws of sentential or first-order logic. How do we know *a priori*, for example, that all the instances of the law of non-contradiction are true, or that all the instances of *modus ponens* are valid?

As I noted above, Frege thought it obvious that there could be no substantive answer to such questions; he was inclined, therefore, to take appearances at face value and to simply *assume* the apriority of logic.

What Frege probably had in mind is the following worry. 'Explaining our knowledge of logic' presumably involves finding some *other* thing that we know, on the basis of which our knowledge of logic is to be explained. However, regardless of what that other thing is taken

to be, it's hard to see how the use of logic is to be avoided in moving from knowledge of that thing to knowledge of the relevant logical truth. And so it can come to seem as if any account of how we know logic will have to end up being vacuous, presupposing that we have the very capacity to be explained.

Michael Dummett has disputed the existence of a real problem here. As he has pointed out, the sort of circularity that's at issue isn't the gross circularity of an argument that consists of including the conclusion that's to be reached among the premises. Rather, we have an argument that purports to prove the validity of a given logical law, at least one of whose inferential steps must be taken in accordance with that law. Dummett calls this a "pragmatic" circularity. He goes on to claim that a pragmatic circularity of this sort will be damaging only to a justificatory argument that

> is addressed to someone who genuinely doubts whether the law is valid, and is intended to persuade him that it is.… If, on the other hand, it is intended to satisfy the philosopher's perplexity about our entitlement to reason in accordance with such a law, it may well do so.[16]

The question whether Dummett's distinction fully allays Frege's worry is a large one, and I can't possibly hope to settle it here. If something along these general lines can't be made to work, then *any* explanation of logic's apriority – or aposteriority, for that matter – is bound to be futile, and the Fregean attitude will have been vindicated.

However, the question that particularly interests me in the present chapter is this: Assuming that the very enterprise of explaining our knowledge of logic isn't shown to be hopeless by Frege's straightforward argument, is there any *special* reason for doubting an explanation based on the notion of analyticity? Quine's enormously influential claim was that there is. I shall try to argue that there isn't – that, in an important sense to be specified later on, our grasp of the meaning of logical claims can explain our *a priori* entitlement to holding them true (provided that the Fregean worry doesn't defeat all such explanations in the first place).

The Classical View and Implicit Definition

It's important to understand, it seems to me, that the analytic theory of the apriority of logic arose indirectly, as a by-product of the attempt to explain in what a grasp of the meaning of the logical constants consists. Alberto Coffa lays this story out very nicely in his book (Coffa, 1991, ch. 14).[17]

What account are we to give of our grasp of the logical constants, given that they are not explicitly definable in terms of *other* concepts? Had they been explicitly definable, of course, we would have been able to say, however plausibly, that we grasp them by grasping their definitions. But as practically anybody who has thought about the matter has recognized, the logical constants are not explicitly definable in terms of other concepts, and so we are barred from giving that account. The question is, what account are we to give?

Historically, many philosophers were content to suggest that the state of grasping these constants was somehow primitive, not subject to further explanation. In particular, such a grasp of the meaning of, say, 'not' was to be thought of as prior to, and independent of, a

decision on our part as to which of the various sentences involving 'not' are to count as true. We may call this view, following Wittgenstein's lead, the doctrine of

> *Flash-Grasping:* We grasp the meaning of, say, 'not' "in a flash" – prior to, and independently of, deciding which of the sentences involving 'not' are true.

On this historically influential picture, Flash-Grasping was combined with the doctrine of Intuition to generate an epistemology for logic:

> *Intuition:* Grasp of the concept of, say, negation, along with our intuition of its logical properties, explains and justifies our logical beliefs involving negation – for example, that 'If not not p, then p' is true.

As Coffa shows, this picture began to come under severe strain with the development of alternative geometries. Naturally enough, an analogous set of views had been used to explain the apriority of geometry. In particular, a flash-grasp of the indefinables of geometry, along with intuitions concerning their necessary properties, was said to explain and justify belief in the axioms of Euclidean geometry.

However, with the development of alternative geometries, such a view faced an unpleasant dilemma. Occupying one horn was the option of saying that Euclidean and non-Euclidean geometries are talking about the *same* geometrical properties, but disagreeing about what is true of them. But this option threatens the thesis of Intuition: If in fact we learn geometrical truths by intuition, how could this faculty have misled us for so long?

Occupying the other horn was the option of saying that Euclidean and non Euclidean geometries are talking about *different* geometrical properties – attaching different meanings to, say, 'distance' – and so not disagreeing after all. But this option threatens the doctrine of Flash-Grasping. Suppose we grant that a Euclidean and a non-Euclidean geometer attach different meanings to 'distance.' In what does this difference consist? Officially, of course, the view is that one primitive state constitutes grasp of Euclidean distance, and another that of non-Euclidean distance. But in the absence of some further detail about how to tell such states apart, and about the criteria that govern their attribution, this would appear to be a hopelessly *ad hoc* and non-explanatory maneuver.

The important upshot of these considerations was to make plausible the idea that grasp of the indefinables of geometry consists precisely in the adoption of one set of truths involving them, as opposed to another. Applied to the case of logic, it generates the semantical thesis that I'll call

> *Implicit Definition:* It is by arbitrarily stipulating that certain sentences of logic are to be true, or that certain inferences are to be valid, that we attach a meaning to the logical constants. More specifically, a particular constant means that logical object, if any, which would make valid a specified set of sentences and/or inferences involving it.

Wittgenstein expressed this reversal of outlook well:

> It looks as if one could *infer* from the meaning of negation that "¬¬p" means p. As if the rules for the negation sign *follow from* the nature of negation. So that in a certain sense there is first of all negation, and then the rules of grammar.

> We would like to say: "Negation has the property that when it is doubled it yields an affirmation." But the rule doesn't give a further description of negation, it constitutes negation. (Wittgenstein, 1976, pp. 52–53, cited in Coffa, 1991, p. 262)

Now, the transition from this sort of implicit definition account of grasp to the analytic theory of the apriority of logic can seem pretty immediate. For it would seem that the following sort of argument is now in place:

(1) If logical constant C is to mean what it does, then argument-form A has to be valid, for C means whatever logical object in fact makes A valid.
(2) C means what it does.

Therefore,

(3) A is valid.

I will return to various questions regarding this form of justification below.[18] For now I want to worry about the fact that neither Carnap nor Wittgenstein was content merely to replace Flash-Grasping with Implicit Definition. Typically, both writers went on to embrace some form of irrealism about logic. Intuitively, the statements of logic appear to be fully factual statements, expressing objective truths about the world, even if necessary and (on occasion) obvious ones. Both Carnap and Wittgenstein, however, seemed inclined to deny such an intuitive realism about logic, affirming in its place either the thesis of logical Non-Factualism or the thesis of logical Conventionalism, or, on occasion, both theses at once.

By logical Non-Factualism,[19] I mean the view that the sentences of logic that implicitly define the logical primitives do not express factual claims and, hence, are not capable of genuine truth or falsity. How, on such a view, are we to think of their semantic function? On the most popular version, we are to think of it as prescriptive, as a way of expressing a rule concerning the correct use of logical expressions. By contrast, logical Conventionalism is the view that, although the sentences of logic are factual – although they can express truths – their truth-values are not objective, but are, rather, determined by our conventions.

Despite this important difference between them, there is an interesting sense in which the upshot of both views is the same, a fact which probably explains why they were often used interchangeably and why they often turn up simultaneously in the analytic theory of logic. For what both views imply is that, as between two different sets of decisions regarding which sentences of logic to hold true, there can be no epistemic fact of the matter. In short, both views imply an epistemic relativism about logic. Conventionalism implies this because it says that the truth in logic is up to us, so no substantive disagreement is possible; and Non-Factualism implies this because it says that there are no truths in logic, hence nothing to disagree about.

Nevertheless, for all this affinity of upshot, it should be quite plain that the two views are very different from – indeed, incompatible with – each other. Conventionalism is a factualist view: it presupposes that the sentences of logic have truth-values. It differs from a realist view of logic in its conception of the *source* of those truth-values, not on their existence. Therefore, although it is possible, as I have noted, to find texts in which

a rule-prescriptivism about logic is combined with Conventionalism, that can only be a confusion.

The important question is: Why did the proponents of Implicit Definition feel the need to go beyond it all the way to the far more radical doctrines of logical Non-Factualism and/or Conventionalism? Whatever problems it may eventually be discovered to harbor, Implicit Definition seems like a plausible candidate for explaining our grasp of the logical constants, especially in view of the difficulties encountered by its classical rival. But there would appear to be little that *prima facie* recommends either logical Non-Factualism or logical Conventionalism. So why combine these dubious doctrines with what looks to be a plausible theory of meaning?

Apparently, both Carnap and Wittgenstein seem to have thought that the issue was forced, that Implicit Definition logically entailed one or the other anti-realist thesis. It seems quite clear that Carnap, for example, believed that Implicit Definition brought Conventionalism immediately in its wake; and Quine seems to have agreed. What separated them was their attitude towards Conventionalism. Carnap embraced it; Quine, by contrast, seems to have been prepared to reject any premise that led to it, hence his assault on the doctrine of Implicit Definition.

But if this is in fact the correct account of Quine's motivations, then they are based, I believe, on a false assumption, for neither form of irrealism about logic follows from the thesis of Implicit Definition.

I will proceed as follows. First, I will argue that Implicit Definition, properly understood, is completely independent of any form of irrealism about logic. Second, I will defend the thesis of Implicit Definition against Quine's criticisms. Finally, I will examine the sort of account of the apriority of logic that this doctrine is able to provide.

Implicit Definition and Non-Factualism

Does Implicit Definition entail Non-Factualism? It is certainly very common to come across the claim that it does. Coffa, for instance, writes that from the new perspective afforded by the doctrine of Implicit Definition, the basic claims of logic are

> our access to certain meanings, definitions in disguise, devices that allow us to implement an explicit or tacit decision to constitute certain concepts.… From this standpoint, necessary claims do not tell us anything that is the case both in the world and in many others, as Leibniz thought, or anything that is the case for *formal* reasons, whatever that might mean, or anything that one is forced to believe due to features of our mind. They do not tell us anything that is the case; so they had better not be called claims or propositions. Since their role is to constitute meanings and since (apparently) we are free to endorse them or not, it is better to abandon the old terminology (a priori "principles," "laws," etc.) that misleadingly suggests a propositional status and to refer to them as "rules." (Coffa, 1991, pp. 265–266)

I have no desire to engage the exegetical issues here; as far as I can tell, the middle Wittgenstein seems very much to have been a non-factualist about the implicit definers of logic, just as Coffa says. What I dispute is that it *follows* from the fact that a given sentence Q is being used to implicitly define one of its ingredient terms, that Q is not a factual sentence, not a sentence that "tells us anything that is the case." These two claims seem to me to be entirely independent of each other.

To help us think about this, consider Kripke's example of the introduction of the term 'meter.' As Kripke imagines it, someone introduces the term into his vocabulary by stipulating that the following sentence is to be true:

(1) Stick S is a meter long at t.

Suppose that stick S exists and is a certain length at t. Then it follows that 'meter' names that length and hence that (1) says that stick S is that length at t, and since it is that length at t, (1) is true.

Knowing all this may not be much of an epistemic achievement, but that isn't the point. The point is that there appears to be no inconsistency whatsoever between claiming that a given sentence serves to implicitly define an ingredient term and claiming that that very sentence expresses something factual.

Similarly, I don't see that there is any inconsistency between supposing that a given logical principle – for instance, the Law of Excluded Middle – serves to implicitly define an ingredient logical constant, and supposing that that very sentence expresses a factual statement capable of genuine truth and falsity.[20]

Implicit Definition and Conventionalism

So far I have argued that it is consistent with a sentence's serving as an implicit definer that that very sentence come to express a fully factual claim, capable of genuine truth and falsity. Perhaps, however, when implicit definition is at issue, the truth of the claim that is thereby fixed has to be thought of as conventionally determined? Does at least Conventionalism follow from Implicit Definition?[21]

It is easy to see, I suppose, why these two ideas might have been run together. For according to Implicit Definition, 'if, then,' for example, comes to mean the conditional precisely by my assigning the truth-value True to certain basic sentences involving it; for example, to

If, if p then q, and p, then q.

And in an important sense, my assigning this sentence the value True is arbitrary. Prior to my assigning it that truth-value, it didn't have a complete meaning, for one of its ingredient terms didn't have a meaning at all. The process of assigning it the value True is simply part of what fixes its meaning. Had I assigned it the value False, the sentence would then have had a *different* meaning. So, prior to the assignment there couldn't have been a substantive question regarding its truth-value. And after the assignment there couldn't be a substantive question as to whether that assignment was correct. In this sense, then, the sentence's truth-value is arbitrary and conventional. Doesn't it follow that Implicit Definition entails Conventionalism?

Not at all. All that is involved in the thesis of Implicit Definition is the claim that the conventional assignment of truth to a sentence determines what proposition that sentence expresses (if any); such a view is entirely silent about what (if anything) determines the truth of the claim that is thereby expressed – *a fortiori*, it is silent about whether our conventions determine it.

Think here again of Kripke's meter stick. If the stick exists and has such-and-so length at t, then it is conventional that 'meter' names that length and, therefore, conventional that (1) expresses the proposition *Stick S has such-and-so length at t*. However, that stick S has that length at t is hardly a fact generated by convention; it presumably had that length prior to the convention, and may continue to have it well after the convention has lapsed.[22]

I anticipate the complaint that the entailment between Implicit Definition and Conventionalism is blocked only through the tacit use of a distinction between a sentence and the proposition it expresses, a distinction that neither Carnap nor Quine would have approved.

Such a complaint would be mistaken, however. The argument I gave relies not so much on a distinction between a sentence and a proposition in the technical sense disapproved of by Quine, as on a distinction between a sentence and *what it expresses*. And it is hard to see how any adequate philosophy of language is to get by without some such distinction.[23] Even on a deflationary view of truth, there is presumably a distinction between the *sentence* 'Snow is white' and that which makes the sentence true, namely, snow's being white. And the essential point for my purposes is that it is one thing to say that 'Snow is white' comes to express the claim that snow is white as a result of being conventionally assigned the truth-value True; and quite another to say that snow comes to be white as a result of our conventions. The first claim is Implicit Definition (however implausibly applied in this case); and the other is Conventionalism. Neither one seems to me to entail the other.

Quine against Implicit Definition: Regress

As I noted above, I am inclined to believe that erroneous opinion on this score has played an enormous role in the history of this subject. I conjecture that had Quine felt more confident that Implicit Definition could be sharply distinguished from Conventionalism, he might not have felt so strongly against it.

In any event, though, whatever the correct explanation of Quine's animus, we are indebted to him for a series of powerful critiques of the thesis of Implicit Definition, critiques that have persuaded many that that thesis, and with it any explanation of the apriority of logic that it might be able to ground, are fundamentally flawed. We must now confront Quine's arguments.

According to Implicit Definition, the logical constants come to have a particular meaning in our vocabulary by our conventionally stipulating that certain sentences (or inferences) involving them are to be true. For instance, let us assume that the meaning for 'and' is fixed by our stipulating that the following inferences involving it are to be valid:

$$(2)\quad \frac{\text{A and B}}{\text{A}} \qquad \frac{\text{A and B}}{\text{B}} \qquad \frac{\text{A, B}}{\text{A and B}}$$

Now, Quine's first important criticism of this idea occurs in his early paper "Truth by convention" (1976a).[24] As Quine there pointed out, there are an infinite number of instances of schema (2). Consequently, the inferences of this infinitary collection could not have

been conventionally stipulated to be valid singly, one by one. Rather, Quine argued, if there is anything at all to this idea, it must be something along the following lines: We adopt certain general conventions, from which it follows that all the sentences of the infinitary collection are assigned the value Valid. Such a general convention would presumably look like this:

> Let all results of putting a statement for 'p' and a statement for 'q' in 'p and q implies p' be valid.

However, the trouble is that in order to state such a general convention we have had, unavoidably, to use all sorts of logical terms – 'every,' 'and,' and so on. So the claim, essential to the proposal under consideration, that all our logical constants acquire their meaning via the adoption of such explicitly formulated conventional assignments of validity must fail. Logical constants whose meaning is not fixed in this way are presupposed by the model itself.[25]

This argument of Quine's has been very influential; and I think that there is no doubt that it works against its target as specified. However, it is arguable that its target as specified isn't the view that needs defeating.

For, surely, it isn't compulsory to think of someone's following a rule R with respect to an expression e as consisting in his *explicitly stating* that rule in so many words in the way that Quine's argument presupposes. On the contrary, it seems far more plausible to construe x's following rule R with respect to e as consisting in some sort of fact about x's *behavior* with e.

In what would such a fact consist? Here there are at least a couple of options. According to a currently popular idea, following rule R with respect to e may consist in our being disposed to conform to rule R in our employment of e, under certain circumstances. On this version, the notion of rule-following would have been *reduced* to a certain sort of dispositional fact. Alternatively, one might wish to appeal to the notion of following a given rule, while resisting the claim that it can be reduced to a set of naturalistically acceptable dispositional facts. On such a non-reductionist version there would be facts about what rule one is following, even if these are not cashable into facts about one's behavioral dispositions, however optimal (see Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING, §2).

For myself, I am inclined to think that the reductionist version won't work, that we will have to employ the notion of following a rule unreduced.[26] But because it is more familiar, and because nothing substantive hangs on it in the present context, I will work with the reductionist version of rule-following. Applied to the case we are considering, it issues in what is widely known in the literature as a "conceptual role semantics" (CRS).

According to this view, then, the logical constants mean what they do by virtue of figuring in certain inferences and/or sentences involving them, and not in others. If some expressions mean what they do by virtue of figuring in certain inferences and sentences, then some inferences and sentences are *constitutive* of an expression's meaning what it does, and others aren't. And any CRS must find a systematic way of saying which are which, of answering the question: What properties must an inference or sentence involving a constant C have, if that inference or sentence is to be constitutive of C's meaning?

Quine against Implicit Definition: Constitutive Truth

Now, Quine's second objection to Implicit Definition can be put by saying that there will be no way of doing what I said any CRS must do – namely, systematically specify the meaning-constituting inferences. Quine formulated this point in a number of places. Here is a version that appears in "Carnap and logical truth":

> if we try to warp the linguistic doctrine of logical truth into something like an experimental thesis, perhaps a first approximation will run thus: *Deductively irresoluble disagreement as to a logical truth is evidence of deviation in usage (or meanings) of words*.… [However] the obviousness or potential obviousness of elementary logic can be seen to present an insuperable obstacle to our assigning any experimental meaning to the linguistic doctrine of elementary logical truth.… For, that theory now seems to imply nothing that is not already implied by the fact that elementary logic is obvious or can be resolved into obvious steps. (Quine, 1976b, p. 105)

Elsewhere, Quine explained his use of the word "obvious" in this connection thus:

> In "Carnap and Logical Truth" I claimed that Carnap's arguments for the linguistic doctrine of logical truth boiled down to saying no more than that they were obvious, or potentially obvious – that is, generable from obvieties by obvious steps. I had been at pains to select the word 'obvious' from the vernacular, intending it as I did in the vernacular sense. A sentence is obvious if (a) it is true and (b) any speaker of the language is prepared, for any reason or none, to assent to it without hesitation, unless put off by being asked so obvious a question. (Quine, 1975, p. 206)

Quine's important point here is that there will be no substantive way of distinguishing between a highly obvious, non-defining sentence and a sentence that is an implicit definer. Both types of sentence – if, in fact, both types exist – will have the feature that any speaker of the language will be prepared to assent to instances of them, "for any reason or none." So in what does the alleged difference between them consist? How is distinctive content to be given to the doctrine of Implicit Definition?[27]

Now, there is no doubt that this is a very good question; and the belief that it has no good answer has contributed greatly to the rejection of the doctrine of Implicit Definition. Fodor and Lepore, for example, base the entirety of their recent argument against a conceptual role semantics on their assumption that Quine showed this question to be unanswerable (Fodor and Lepore, 1991a).

If Quine's challenge is allowed to remain unanswered, then the threat to the analytic theory of the *a priori* is fairly straightforward. For if there is no fact of the matter as to whether S is a sentence that I must hold true if S is to mean what it does, then there is no basis on which to argue that I am entitled to hold S true without evidence.

But that would seem to be the least of our troubles, if Quine's argument is allowed to stand; for what's threatened is not only the apriority of logical truths but, far more extremely, the *determinacy* of what they claim. For as I've already pointed out, and as many philosophers are anyway inclined to believe, a conceptual role semantics seems to be the *only* plausible view about how the meaning of the logical constants is fixed. It follows, therefore, that if there is no fact of the matter as to which of the various inferences involving a constant are meaning-constituting, then there is also no fact of the matter as to what the logical

constants themselves mean. And that is just the dreaded indeterminacy of meaning on which the critique of analyticity was supposed not to depend.

The simple point here is that if the only view available about how the logical constants acquire their meaning is in terms of the inferences and/or sentences that they participate in, then any indeterminacy in what those meaning-constituting sentences and inferences are will translate into an indeterminacy about the meanings of the expressions themselves. This realization should give pause to any philosopher who thinks he can buy in on Quine's critique of Implicit Definition without following him all the way to the far headier doctrine of meaning-indeterminacy.

There has been a curious tendency to miss this relatively simple point. Fodor seems a particularly puzzling case; for he holds all three of the following views. (1) He rejects indeterminacy, arguing forcefully against it. (2) He follows Quine in rejecting the notion of a meaning-constituting inference. (3) He holds a conceptual role view of the meanings of the logical constants. As far as I am able to judge, however, this combination of views is not consistent.[28]

Part of the explanation for this curious blindness derives from a tendency to view Quine's argument as issuing not in an indeterminacy about meaning, but, rather, in a *holism* about it. In fact, according to Fodor and Lepore, the master argument for meaning holism in the literature runs as follows:

(1) Some of an expression's inferential liaisons are relevant to fixing its meaning.
(2) There is no principled distinction between those inferential liaisons that are constitutive and those that aren't. (The Quinean result)

Therefore,

(3) All of an expression's inferential liaisons are relevant to fixing its meaning. (Meaning Holism)

Fearing this argument's validity, and seeing no way to answer Quine's challenge, Fodor and Lepore spend their whole book trying to undermine the argument's first premise, namely, the very plausible claim that at least *some* of an expression's inferential liaisons are relevant to fixing its meaning (see Fodor and Lepore, 1991b).

But they needn't have bothered, for I don't see how the master argument could be valid in the first place. The claim that *all* of an expression's inferential liaisons are constitutive of it cannot cogently follow from the claim that it is *indeterminate* what the constitutive inferences are. If it's *indeterminate* what the constitutive inferences are, then it's genuinely *unsettled* what they are. And that is inconsistent with saying that they are *all* constitutive, and inconsistent with saying that *none* are constitutive, and inconsistent with saying that some specified subset are constitutive.

Fodor and Lepore are not alone in not seeing the problem here. Let me cite just one more example. In his comments on an earlier version of the present chapter, Harman says:

> Can one accept Quine's argument against analyticity without being committed to the indeterminacy of meaning? Yes and no. By the "indeterminacy of meaning" might be meant an indeterminacy as to which of the principles one accepts determine the meanings of one's terms and

> which simply reflect one's opinions about the facts. Clearly, Quine's argument against analyticity is committed to that sort of indeterminacy. [However] that by itself does not imply full indeterminacy in the sense of Chapter 2 of *Word and Object*. (Harman, 1994b)

As Harman correctly says, Quine has to deny that there is a fact of the matter as to which of T's principles determine the meanings of his terms and which simply reflect T's opinions about the facts – that, after all, is just what it is to deny that there are facts about constitutivity. However, Harman insists, this denial in no way leads to the indeterminacy thesis of chapter 2 of *Word and Object*.

But this is very puzzling. Against the background of a conceptual role semantics, according to which the meaning of T's term C is determined precisely by a certain subset of the principles involving C that T accepts, an indeterminacy in what the meaning-determining principles are will automatically lead to an indeterminacy in what the meaning is, in the full sense of chapter 2 of *Word and Object*. If a subset (not necessarily proper) of accepted principles is supposed to determine meaning; and if there is no fact of the matter as to which subset that is; then there is, to that extent, no fact of the matter as to what meaning has been determined. Since correct translation is supposed to preserve meaning, it follows that there can be no fact of the matter as to what counts as correct translation.

I think there is really no avoiding the severe conclusion that meaning is indeterminate, if the Quinean challenge to constitutivity is allowed to remain unanswered. I'm inclined to think, therefore, that anyone who rejects radical indeterminacy of meaning must believe that a distinction between the meaning-constituting and the non-meaning-constituting can be drawn. The only question is how.

Well, that is not the task of the present chapter. Although there are some good ideas about this, I don't have a fully thought-through proposal to present just now.[29] My main aim here is not to *solve* the fundamental problem for a conceptual role semantics for the logical constants; rather, as I have stressed, it is to show that, against the background of a rejection of indeterminacy, its insolubility cannot be conceded.

Pending the discovery of other problems, then, it seems open to us to suppose that a plausible theory of meaning for the logical constants is given by something like the following:

> A logical constant C expresses that logical object, if any, that makes valid its meaning-constituting inferences or sentences.

Implicit Definition, Justification, and Entitlement

Now, how does any of this help vindicate the analytic theory of the apriority of logic, the idea that logic is epistemically analytic? Let us consider a particular inference form, A, in a particular thinker's (T) repertoire; and let's suppose that that inference form is constitutive of the meaning of one of its ingredient constants C. How, exactly, might these facts help explain the epistemic analyticity of A for T?

To say that A is epistemically analytic for T is to say that T's knowledge of A's meaning alone suffices for T's justification for A, so that empirical support is not required. And it does seem that a conceptual role semantics can provide us with a model of how

that might be so. For given the relevant facts, we would appear to be able to argue as follows:

(1) If C is to mean what it does, then A has to be valid, for C means whatever logical object in fact makes A valid.
(2) C means what it does.

Therefore,

(3) A is valid.

Now, it is true that this is tantamount to a fairly broad use of the phrase "knowledge of the meaning of A," for this knowledge includes not merely knowledge of what A means, strictly so called, but also knowledge of how that meaning is fixed. But this is, of course, both predictable and unavoidable: there was never any real prospect of explaining apriority merely on the basis of a knowledge of propositional content. Even Carnap realized that one needed to know that a given inference or sentence had the status of a 'meaning postulate.'

But isn't it required, if this account is to genuinely explain T's *a priori* justification for the basic truths of logic, that T know the premises *a priori* as well? Yet, it hasn't been shown that T can know the premises *a priori*.

It is quite correct that I have not attempted to show that the relevant facts about meaning cited in the premises are knowable *a priori*, although I believe that it is intuitively quite clear that they are. I have purposely avoided discussing all issues relating to knowledge of meaning-facts. My brief here has been to defend epistemic analyticity; and this requires showing only that certain sentences are such that, *if* someone knows the relevant facts about their meaning, *then* that person will be in a position to form a justified belief about their truth. It does not require showing that the knowledge of those meaning-facts is itself *a priori* (although, I repeat, it seems quite clear to me that it will be).[30]

Isn't it a problem for the aspirations of the present account that a thinker would have to use *modus ponens* to get from the premises to the desired conclusion?

Not if Dummett's distinction between pragmatic and vicious circularity is credited with opening a space for an epistemology for logic, as discussed above.

Finally, how could such an account possibly hope to explain the man in the street's justification for believing in the truths of logic? For such a person, not only would the relevant meaning-facts be quite opaque, he probably wouldn't even be capable of framing them. Yet such a person is obviously quite justified in believing the elementary truths of logic. Thus, so our objector might continue, this sort of account cannot explain our ordinary warrant for believing in logic; at best, it can explain the warrant that sophisticates have.

I think that, strictly speaking, this objection is correct, but only in a sense that strips it of real bite. Philosophers are often in the position of articulating a warrant for an ordinary belief that the man in the street would not understand. If we insist that a person counts as justified only if they are aware of the reason that warrants their belief, then we will simply have to find another term for the kind of warrant that ordinary folk often have and that philosophers seek to articulate. Tyler Burge has called it an "entitlement":

> The distinction between justification and entitlement is this. Although both have positive force in rationally supporting a propositional attitude or cognitive practice, and in constituting an

> epistemic right to it, entitlements are epistemic rights or warrants that need not be understood by or even be accessible to the subject.… The unsophisticated are entitled to rely on their perceptual beliefs. Philosophers may articulate these entitlements. But being entitled does not require being able to justify reliance on these resources, or even to conceive such a justification. Justifications, in the narrow sense, involve reasons that people have and have access to. (Burge, 1993, p. 458)

When someone is entitled, all the facts relevant to the person's justification are already in place, so to say; what's missing is the reflection that would reveal them.

Just so in the case at hand. If a conceptual role semantics is true, and if A is indeed constitutive of C's meaning what it does, then those facts by themselves constitute a warrant for A; empirical support is not necessary. A can only be false by meaning something other than what it means. But these facts need not be known by the ordinary person. They suffice for his entitlement, even if not for his full-blown justification. This full-blown justification can be had only by knowing the relevant facts about meaning.

Conclusion

Quine helped us see the vacuity of the metaphysical concept of analyticity and, with it, the futility of the project it was supposed to underwrite – the linguistic theory of necessity. But I don't see that those arguments affect the epistemic notion of analyticity that is needed for the purposes of the theory of *a priori* knowledge. Indeed, it seems to me that epistemic analyticity can be defended quite vigorously, especially against the background of a realism about meaning.

On the assumption that our warrant for believing in elementary logical truths cannot be explained, the outstanding problem is to explain our *a priori* knowledge of conceptual truths. For this purpose, the crucial semantical notion is that of Frege-analyticity. I have argued that this notion is bound to be in good standing for a meaning realist.

If the project of explaining logic is not ruled hopeless, then I have tried to show how the doctrine that appears to offer the most promising account of how we grasp the meanings of the logical constants – namely, Implicit Definition – can explain the epistemic analyticity of our logical beliefs and, hence, our *a priori* warrant for believing them. As long as we are not prepared to countenance radical indeterminacy, we should have every confidence that this form of explanation can be made to work.

Appendix: *A Priori* Knowledge of the Second Premise

I have argued that a conceptual role semantics supplies the following sort of warrant for our belief in the elementary truths of logic.

(1) If C is to mean what it does, then A has to be valid, for C means whatever logical object in fact makes A valid.
(2) C means what it does.

Therefore,

(3) A is valid.

In this Appendix I want to propose a reason for holding that the second premise in this argument form is knowable *a priori*.

The challenge might appear, at first, to be utterly trivial. Surely, we know, for any given C, that it means whatever it means. Suppose C is the word "and"; then, surely, we know *a priori* that "and" means whatever it means. Indeed, isn't it clear that we know *a priori* precisely what it does mean, namely, *and*? For any given mentioned constant, isn't disquotation guaranteed to state its meaning accurately?

What all such purely disquotational views of our knowledge of meaning ignore is the possibility that the words we are disquoting fail to have a meaning in the first place. What the disquotational maneuver guarantees is only that, *if* a word has a meaning, then disquotation will state its meaning correctly. However, the disquotational view does not, and cannot, address the question of how we know that the word has a meaning to begin with.

This point is interestingly related to a point made by Harman in the following passage:

> Even if conventional assignments of truth or falsity determine meaning, it does not follow that a sentence is true by virtue of convention. It does not even follow that the sentence is true. (Harman, 1968, pp. 130–131; see also Quine, 1976a, pp. 93–95; 1976b, p. 114)

Harman's claim is that, even if we put aside objections to the thesis of Implicit Definition, it wouldn't follow that a meaning-constituting sentence is true. Hence, we couldn't claim to be entitled to S without evidence, just because S is meaning-constituting. Perhaps S is meaning-constituting and not true.

How might this happen? Harman doesn't explain: but it's important to ask. How might it turn out that a sentence that is stipulated to be true, as a way of fixing the meaning of some ingredient term t, nevertheless fail to be true?

One thing is, I think, certain: not by being false. For to be false, S would have to be meaningful. And it is stipulated that, if S expresses any meaning at all, it expresses a true one. Under these assumptions, therefore, S can fail to be true only by expressing no meaning whatever. And this in turn will happen only if one of its ingredient terms fails to express a meaning.

So let us ask: How might it turn out that a set of constitutive rules for a term t fail to determine a meaning for it? I can think of two ways. First, the meaning-constituting role specified for t may impose inconsistent demands on it, thus making it impossible for there to be a meaning that makes true all of its meaning-constituting sentences. A second worry might arise simply against the background of a robust propositionalism, without exploiting worries about inconsistency. For according to a robust propositionalism, meanings are radically mind-independent entities whose existence no amount of defining could ensure. Hence, there may well not be a meaning answering to all the demands placed upon a term by a set of stipulations.[31]

For both of these reasons, then, we cannot immediately conclude from the fact that t is governed by a set of meaning-constituting rules, that t is meaningful.

To put this point in terms of the second premise of the argument-form outlined above, the fact that a given constant C is governed by certain constitutive rules of use doesn't by itself entitle us to conclude that C means what it does, because it doesn't by itself entitle us to conclude that C has a meaning in the first place. Hence, we cannot lean on a disquotational view to vindicate our claim that the second premise is knowable *a priori*.

A Solution

So how are we to proceed? Is there an *a priori* way of laying to rest a doubt about the meaningfulness of our logical constants? I think we can make a case for the following claim: we are *a priori* entitled to believe that our basic logical constants are meaningful because we cannot coherently doubt that they are. For the assumption that our constants are meaningful is presupposed in any attempt to claim that they aren't.

I shall assume that, prior to having seen the desirability of introducing an alternative set of logical constants, we start off with a particular, single set of these. For the sake of specificity, let us assume that these constants are classical, that is, that they are governed by classical constitutive rules. As will become clear, this assumption is absolutely inessential to the argument that follows.

Now, consider what a first attempt to formulate a skepticism about the meaningfulness of our constants would look like. The Skeptic wishes to assert that our basic logical constants do not express a meaning. Given the assumption that our constants are classical, the Skeptic's assertion comes down to a claim about the meaningfulness of the basic pair of constants in terms of which all the others can be defined – let's suppose that that pair consists of negation and the conditional. In the case of negation, the Skeptic would appear to want to claim:

(4) ∀x (If x is a token of 'not,' then x does not have a meaning);

and in the case of 'if, then' this:

(5) ∀x (If x is a token of 'if, then,' then x does not have a meaning).

The problems with both (4) and (5), however, are not easy to miss. In attempting to state that our basic logical constants fail to be meaningful, both claims have to assume that those very constants *are* meaningful. No one could rationally wish to assert (4) or (5) who did not believe that negation and the conditional are meaningful; yet what (4) and (5) claim is that negation and the conditional are not meaningful (respectively). It would appear, therefore, that any attempt to assert (4) and (5) would be self-defeating: the very act of putting those propositions forward undermines the truth of the propositions that are being put forward.

A number of possible lines of objection need to be considered. First, does the argument especially depend on the particular selection of basic logical constants? Would it work equally well if, say, negation and disjunction had been chosen as the reduction base, rather than negation and the conditional?

It is hard to see how the particular selection can make any difference. It is relatively trivial to show that, regardless of the particular choice of reduction base, the same style of argument goes through, with similar effect.

A second, somewhat more challenging line of objection runs as follows. Let's concede that an assertion of (4) would be self-defeating: we cannot use the constants we have to assert of *them* that they are meaningless.[32] But why couldn't we introduce some *new* constants and use them to formulate a skepticism about the old ones? (Notice that I don't need to make any assumptions about what these prior constants are, whether classical or otherwise.) Such a claim would look like this:

(6) ∀x (If x is a token of 'not,' then x does not_{N} refer),

where the subscript 'N' indicates that the constant is one of the *new* ones. There appears to be nothing self-stultifying about this thesis.

I don't think that this objection works either, though its problems are slightly better hidden. The problem is that the integrity of the old constants is presupposed in *the very act of introducing the new alternatives*.

Recall, we are operating on the assumption that we start off with a determinate set of logical constants. By further, and ultimately optional, assumption, these constants are classical. Now we wish to introduce an alternative set of constants, so that we may use them to state, of the old constants, that they are meaningless. Consider how such an introduction would have to go. We would need to say what the constitutive rules governing the new constants are, and that they are *all* of them. That is, we would need to say something along the following lines (where the subscript 'N' indicates that the constant is *new*):

(7) ∀x (If x is a token of 'not_N,' then x is subject to rules R1, R2, R3, and no others).

Clearly, however, in this definition the meaningfulness of many of the old constants – in particular, negation, the conditional, and the universal quantifier – is presupposed. And there appears to be no way to cancel that presupposition without jeopardizing the meaningfulness of the new constants with the use of which the skeptical hypothesis is to be formulated. Unless the old constants *are* meaningful, the stipulations will fail to give the new constants a particular meaning. Hence, we cannot coherently suppose both that the new constants have a meaning and that the old ones don't.

As far as I am able to judge, every attempt to formulate a worry about the meaningfulness of our basic logical constants runs into a similar sort of difficulty: every such attempt ends up presupposing the integrity of the constants whose integrity it seeks to question.

An enormous number of questions are left outstanding, none of which can be adequately dealt with here. For one: Is this merely a pragmatic result, or something stronger? Tentative answer: Something stronger. To sustain the claim that the result is merely pragmatic, one would have to make sense of the claim that, although we cannot rationally doubt that our constants are meaningful, it is nevertheless possible that they aren't. However, considerations similar to the ones adduced above would tend to show that we cannot make sense of this thought either.

Another question: Doesn't this argument prove too much? Some of the best recent philosophy has taken the form of claiming that various of the rules of classical logic make unsatisfiable demands on our ability to mean what we do by our words and, hence, that they are incoherent. Isn't any criticism of this form disabled by the above argument?

Not at all. My argument does nothing to preclude the following sort of view: Our constants are essentially intuitionistic – that is, they are governed by a core set of intuitionistic rules. However, some philosophers and mathematicians have mistakenly supposed that they are also subject to certain further rules – they have mistakenly supposed, in other words, that our constants are classical. However, they are mistaken in this: not only are our constants not classical, but they couldn't have been, because creatures like us are incapable of meaning classical constants.

Nothing in my argument prevents someone from adopting the sort of view outlined in the preceding paragraph. What my argument does preclude is the simultaneous assertion that our ordinary constants are classical *and* that they are incoherent. As far as I can see,

though, no one with an interest in criticizing classical logic need put his position in that manifestly problematic way.[33,34]

Notes

1 Consider, for example, the following passage from Quine (1970, p. 3):

> My objection to recognizing propositions does not arise primarily from philosophical parsimony – from a desire to dream of no more things in heaven and earth than need be. Nor does it arise, more specifically, from particularism – from a disapproval of intangible or abstract entities. My objection is more urgent. If there were propositions, they would induce a certain relation of synonymy or equivalence between sentences themselves: those sentences would be equivalent that expressed the same proposition. Now my objection is going to be that the appropriate equivalence relation makes no objective sense at the level of sentences. This, if I succeed in making it plain, should spike the hypothesis of propositions.

2 As I say, I am going to work with this linguistic picture out of deference to my opponents. I would prefer to work with a propositionalist picture of belief. Most of the crucial notions developed in this chapter, and much of the argument involving them, can be translated, with suitable modifications, into this propositionalist framework. Thus, even those who believe, as I do, that knowledge is not a matter of knowing that certain sentences are true can find use for the account developed here.

3 The inclusion of the word "outer" here is partly stipulative. I have always found it natural to regard *a priori* knowledge as encompassing knowledge that is based on no experience as well as knowledge that is based purely on *inner* experience.

4 In the interests of brevity, I shall henceforth take it as understood that "justification" means "justification with a strength sufficient for knowledge."

5 Even this strong notion is not as demanding as many have supposed. For instance, it is consistent with a belief's being *a priori* in the strong sense that we should have *pragmatic* reasons for dropping it from our best overall theory. For illuminating discussion of the modesty of the notion of the *a priori*, see Wright (1984) and Hale (1986, ch. 6).

6 I am indebted to Paul Horwich for emphasizing the importance of this point.

7 See Frege (1950). (Some may regard the attribution of precisely this notion to Frege controversial. What matters to me is not who came up with the idea, but rather the philosophical role it has played.)

My use of the term 'analytic' in connection with Frege's *semantical* notion as well as with the preceding epistemic and metaphysical concepts may be thought ill advised. But I do so deliberately, to highlight the fact that the term has been used in the literature in general, and in Quine in particular, to stand for all three different sorts of notion, often without any acknowledgement of that fact. This terminological promiscuity has undoubtedly contributed to the confusion surrounding discussions of this issue.

8 For some discussion, see Boghossian (1994a).

9 Exegetically, this does leave us with a couple of puzzles. First, "Two dogmas" does contain a brief discussion of the implicit definition idea, under the guise of the notion of a "semantical rule." Given that, why does Quine insist that he intends only to discuss the notion of Frege-analyticity? Second, the notion of a semantical rule is discussed only in connection with non-logical truths: since, however, the deployment of this idea would be exactly the same in the logical case, why is the analyticity of logic expressly excluded? Third, given that the analyticity of logic is expressly excluded, on what basis does Quine allow himself to draw morals about logic's revisability towards the end of "Two dogmas"? I think there is no avoiding the conclusion that, on this and other related issues (see below), "Two dogmas" is confused. It would, in fact, have been surprising if these rather tricky problems had all been in clear focus in Quine's pioneering papers.

10 In this context, nothing fancy is meant by the use of such expressions as 'property' and 'proposition.' For present purposes they may be understood in a thoroughly deflationary manner.

I have sometimes been asked why I consider just this particular weakening of a non-factualist thesis, one that involves, problematically from Quine's official point of view, a modal notion? Why not rather attribute to him the following *Very Weak Thesis*:

> (VWT) There is a coherent, determinate property expressed by 'is analytic,' but *as a matter of fact*, it has never been instantiated; consequently, all tokens of the sentence 'S is analytic' have been false up to now.

There are two reasons. First, the VWT is not a philosophically interesting thesis; and, second, it could not have been argued for on the basis of a *philosophy* paper – i.e., on the sorts of *a priori* grounds that Quine offers. So although Quine may not be entitled to precisely the ET, I am going to ignore that and not hold it against him.

11 This question was first asked by Grice and Strawson (1989). Grice and Strawson didn't sufficiently stress, however, that Quine was committed to a skepticism even about *intralinguistic* synonymy, and not just about inter-linguistic synonymy, for the theory of apriority doesn't much care about the inter-linguistic case.

12 Formulations of this argument may be found in Fodor (1987, pp. 62 ff.), Fodor and Lepore (1991b, pp. 37 ff.), and Devitt (1995, p. 17). None of the authors mentioned approve of the argument.

13 A further "Two dogmas"-based argument for meaning holism, this time invalid, will be considered further below, in connection with the discussion of the thesis of Implicit Definition.

14 As before, subject to the proviso about the apriority of synonymy.

15 I am ignoring for now the class of *a priori* truths that are neither logical nor Frege-analytic. As we shall see, the very same strategy – implicit definition – that can be applied to explain our knowledge of logic can be applied to them as well.

16 Dummett (1991, p. 202). Dummett's distinction is deployed in a somewhat different context.

17 In the next three paragraphs I follow the general contours of the account that Coffa develops. However, the formulations are mine and they differ in important respects from Coffa's, as we shall see further on.

18 Readers who are acquainted with a paper of mine entitled "Inferential role semantics and the analytic/synthetic distinction" (Boghossian, 1994b), will be aware that I used to worry that Implicit Definition could not generate *a priori* knowledge because of the falsity of something I called "The Principle." The Principle is the thesis that it follows from a sentence's being an implicit definer that that sentence is true. The proper place of this issue in the overall dialectic, and a proposed solution, are discussed in the Appendix to the present chapter.

19 Not to be confused with the non-factualism about Frege-analyticity discussed earlier in the chapter.

20 Someone may object that the two cases are not relevantly analogous. For the meter case is supposed to be a case of the *fixation of reference*, but the logical case an instance of the fixation of meaning. Doesn't this difference between them block the argument I gave?

I don't see that it does. First, the two cases really are disanalogous only if there is an important difference between meaning and reference; yet, as is well known, there are many philosophers of language who are inclined to think that there isn't any such important difference. Second, it seems to me that even if we allowed for a robust distinction between meaning and reference, the point would remain entirely unaffected. Whether we think of an implicit definer as fixing a term's reference directly, or as first fixing its meaning, which then in turn fixes its reference, seems to me entirely irrelevant to the claim that Implicit Definition does not entail Non-Factualism. As long as both processes are consistent with the fixation of a factual claim for the sentence at issue – as they very much seem to be – the point stands.

21 Certainly many philosophers seem to have thought so. Richard Creath, for example, sympathetically expounds Carnap's view that the basic axioms of logic implicitly define the ingredient

logical terms by saying that on this view "the postulates (together with the other conventions) create the truths that they, the postulates express." See Creath (1992, p. 147).

22 This point is also forcefully made by Salmon (1993) and Yablo (1992).

23 Notice that conventionalists themselves need to make crucial use of such a distinction when they describe their own position, as in the passage cited above from Creath: "the postulates (together with the other conventions) create the truths that they, the postulates, express." As Hilary Putnam pointed out some time ago, it's hard to see how distinctive content is to be given to Conventionalism without the use of some such distinction. For a conventionalism merely about linguistic expressions is trivial. A real issue is joined only when the view is formulated as a claim about the truths expressed. See Putnam (1975).

24 Quine's argument here is officially directed against a Conventionalism about logical truth, that is, against the idea that logical truth is determined by our conventions. This idea we have already rejected in our discussion of the metaphysical concept of analyticity. However, Quine attacks Conventionalism *by* attacking the semantical thesis of Implicit Definition. Hence the need for the present discussion.

25 Quine claims that this argument may also be put as follows: The claim that the sentences of logic lack assignment of truth-value until they are conventionally assigned such values must fail. For logic is needed in order to infer from a formulated general convention that the infinitely many instances of a given schema are true. Hence, sentences of logic whose truth-value is not fixed as the model requires are presupposed by the model itself.

It's unclear to me that this is a formulation of precisely the same argument. However, to the extent that it is distinct, it is also addressed by the proposal I put forth below.

26 For discussion, see Boghossian (1989).

27 For all its influence, it is still possible to find the force of the Quinean point being underestimated by the friends of Implicit Definition. Christopher Peacocke, for example, in a subtle defense of an inferential role semantics, claims that what makes the inferences involving the logical constants constitutive is that a thinker finds those inferences "primitively compelling," and does so because they are of those forms. He goes on to explain:

> To say that a thinker finds such instances primitively compelling is to say this: (1) he finds them compelling; (2) he does not find them compelling because he has inferred them from other premises and/or principles; and (3) for possession of the concept in question … he does not need to take the correctness of the transitions as answerable to anything else. (Peacocke, 1992, p. 6)

I think it is plain, however, that these conditions are insufficient for answering the Quinean challenge: a non-constitutive, though highly obvious, form of inference may also be found compelling because of its form, and not on the basis of inference from anything else. So these conditions cannot be what distinguish between a constitutive and a non-constitutive inference.

28 For Fodor's views on the mentioned issues, see Fodor (1987; 1994).

29 For a good start, see Peacocke (1992).

30 For a discussion of why the second premise is *a priori* see the Appendix to the present chapter.

31 This, I believe, was the basis of Arthur Prior's worry about an inferential role semantics; it was unfortunate that he tried to illustrate his point in a way that misleadingly suggested that his was a worry of the first sort, about consistency. See Prior (1967).

32 This was suggested to me in conversation by Hartry Field.

33 For much more on all this, see my "Knowledge of logic" (2000).

34 I am grateful to a number of audiences – at MIT, CUNY Graduate Center, Michigan State, the University of Chicago, the SOFIA Conference on Tenerife, the Chapel Hill Colloquium, Dartmouth College, London University, and Oxford University. An earlier version of this chapter was presented at the NEH Institute on the "Nature of Meaning," held at Rutgers University in the summer of 1993. It was there that I first became aware that Christopher Peacocke has been thinking

along somewhat similar lines about the *a priori* – see his "How are a priori truths possible?" (1993) presented at the Rutgers conference. Although there are a number of differences between our approaches, and although Peacocke's focus is not on the notion of analyticity, I have benefited from discussing these matters with him. Another philosopher to whom I am grateful for numerous illuminating conversations is Jerry Katz. Although Katz carves up the issues in this area very differently than I do, he deserves an enormous amount of credit for keeping the topic of analyticity alive during a period when it was extremely unfashionable to do so. I also benefited from presenting a version of this chapter as part of a symposium on Analytic Truth, involving Gil Harman, Burton Dreben, and W.V.O. Quine, at the 1994 Eastern Division meetings of the APA. I am especially grateful to Gil Harman, Elizabeth Fricker, Hartry Field, Gary Gates, Bill Lycan, Stephen Schiffer, and Barry Loewer for their detailed comments on previous versions of this chapter. Special thanks are due to Bob Hale and Crispin Wright for their patience and for their very helpful reactions to several different drafts. For other helpful discussion and commentary, I want to thank Jennifer Church, Jerry Fodor, Albert Casullo, Norma Yunez, Neil Tennant, Peter Unger, Tom Nagel, Paul Horwich, Ned Block, Richard Creath, Allan Gibbard, Stephen Yablo, and David Velleman.

Postscript: Further Thoughts about Analyticity: 20 Years Later

PAUL ARTIN BOGHOSSIAN

Introduction

One central thesis of the chapter[1] to which the present piece is an afterword was that two fundamentally distinct notions had been conflated under the label 'analytic' – an epistemological notion and a metaphysical one.[2]

A second central thesis was that while the critics of analyticity, Quine (1953) and Harman (1967) principally among them, were right to disparage the metaphysical notion, the epistemological notion could be shown to be cogent and to serve a useful role in the theory of *a priori* justification.

According to the metaphysical notion,

> A sentence S is *metaphysically analytic* if and only if it is true (false) by virtue of its meaning alone (without any contribution from the world).

By contrast, the epistemic notion has it that

> A sentence S is *epistemically analytic* if and only if it is possible to justifiably believe S merely by virtue of understanding S's meaning (and without any contribution from sensory experience).

There had been a pervasive tendency in the literature to conflate these two ideas, as is illustrated by the following representative passage from BonJour (1998, p. 28):

> the moderate empiricist position on a priori knowledge holds that while such knowledge genuinely exists … it is nonetheless merely analytic in character – that is, very roughly, merely a product of human concepts, meaning, definitions, or linguistic conventions. Such knowledge thus says nothing substantive about the world.

In the 20 or so years since "Analyticity" was first published, the importance of distinguishing between the metaphysical and epistemological concepts has come to be widely accepted. It has become commonplace in discussions of analyticity to cite the distinction and to respect its substance.[3]

More controversial than the distinction itself has proven to be my claim that epistemic analyticity can play a significant role in explaining *a priori* justification. Also contentious, although to a much lesser degree, has been my rejection of the notion of metaphysical analyticity.

Gillian Russell (2008) put up an interesting defense of the metaphysical notion. Her arresting thought is that developments in our understanding of the notion of meaning, since Quine's famous discussion, provide previously unavailable routes to a coherent conception of 'truth solely in virtue of meaning.'

In my (2011) I explain why I am not persuaded by Russell's arguments; but I believe, nonetheless, that they deserve the considerable attention they have received. Recently, Bob Hale and Crispin Wright (forthcoming) and Jared Warren (2014) have also advanced important defenses of the metaphysical notion. David Liggins (ms.) has an interesting analysis of some of the framework issues involved.

A more vigorous debate has centered on the claim that epistemological analyticity can play a central role in the epistemology of *a priori* justification. In connection with this issue, four big questions arise:

1. Can we explain *all a priori* justification via epistemic analyticity?
2. Assuming not, does that imply that we can't explain *any a priori* justification through epistemic analyticity? Is uniformity a requirement on the explanation of justification in the *a priori* domain?

3. Assuming uniformity is not a requirement, is there *any a priori* justification that we can explain via epistemic analyticity?
4. If we can explain some, how would it work?

I will look, inevitably too briefly, at some developments in my thinking about these issues since the initial appearance of "Analyticity."

Can Epistemic Analyticity Explain All *A Priori* Justification?

Throughout my explorations of the idea of epistemic analyticity I've never claimed that it can explain *all* cases of *a priori* justification. I was mostly concerned to show that the epistemically analytic was capable of explaining our knowledge of conceptual truths and of the basic truths and inferences of logic.

However, any proponent of epistemic analyticity must eventually confront the question whether all *a priori* justification can be explained in these terms. Over the years, it has become clear to me that the answer to this question has to be 'No.'

The famous case of color exclusion, for example, resists explanation in terms of epistemic analyticity. I know *a priori* that nothing can be red and green all over at the same time. But knowledge of this fact is not encoded in my grasp of the relevant color concepts, as can be seen from the following considerations. Knowledge of the exclusion does not reside in my grasp of the concept *red,* because I could have the concept *red* without so much as having the concept *green.* The concept *red* couldn't be speaking negatively about its compatibility with green, so to say, because it doesn't speak about it at all. Vice versa for the concept *green*.

At best, then, knowledge of the exclusion would have to reside in the *joint possession* of *red* and *green*. But isn't the joint possession of *red* and *green* just the simultaneous possession of each? If that's right, then joint possession can't contain any information that's not contained in the sum of what's contained in each.

As a result, we can't explain our *a priori* knowledge of the way in which red excludes green merely on the basis of our understanding of the ingredient color concepts. If we are nevertheless able to figure it out we must be relying on something else.[4]

A second kind of case that's problematic for epistemic analyticity arises when the concepts in question *do* speak of a necessary relation obtaining between two properties but where that doesn't suffice for claiming that the relation obtains in reality.

This seems to be the case with *normative* truths. Take morality. On the basis of a Trolley thought experiment, you might conclude that it is not morally permissible to throw the fat man off the bridge in order to stop the oncoming trolley and save the five innocent persons strapped to the rails below. But it would not be plausible to claim that your judgment derives solely from your understanding of the ingredient concepts.

The reason why is related to Moore's Open Question Argument (Moore, 1903). If someone tells us that, according to his concept of *good*, the good always involves some particular property – maximizing happiness, for example – we can always ask: But is that the *correct* concept of good, the one that delivers genuinely normative results, as opposed to simply telling us what's good according to your concept?

Notice the contrast here with the concept *square*. If someone said: According to my concept *square*, a square always has four sides, it wouldn't make any sense to ask: But is that the

correct concept *square*? By contrast, it always seems to make sense to ask this question about correctness of any particular normative concept.

If this is right, then we can't explain our *a priori* moral knowledge on the basis of our understanding of the ingredient concepts. If we are nevertheless able to figure it out, it seems as though we must be relying on something else.

Is Uniformity a Requirement?

If the argument up to this point is correct, then not all *a priori* justification can be explained via the understanding alone. But is it open to us to suppose that justification in the *a priori* domain may have more than one source? Doesn't the argument up to this point imply that *no a priori* justification can be explained via epistemic analyticity?

I don't believe that all instances of *a priori* justification need have the same source.

There is an interesting contrast here with the empirical. Because the 'empirical' has a positive characterization, there is no question that it has a unified source – namely, sensory experience. (That's not to deny, of course, that there are different subspecies of empirical knowledge – for example, inferential versus observational.)

But the *a priori* is defined as that which is *not* empirical. And this means that it is not guaranteed up front that everything that is *a priori* will have the same epistemic basis. For all that the notion of the *a priori* implies it's possible that some *a priori* justification has its source in understanding and the rest in some other source, for example, intuition.

We should be open to the suggestion that *a priori* justification is generated in several different ways, using different resources.

Can Epistemic Analyticity Explain Even Some Cases of *A Priori* Justification?

But can we in fact explain *any* cases of *a priori* justification through epistemic analyticity?

Let us look at sentences and inferences where such explanations seem most plausible:

(1) All squares have four sides.
(2) All foxes are foxes.
(3) If all vixens are foxes, and all foxes are mammals, then all vixens are mammals.
(4) All vixens are foxes and all foxes are mammals, so: All foxes are mammals.
(5) Anyone who knows p believes p.

If a sentence S is epistemically analytic, we have said, then an understanding of its meaning suffices for our being able to justifiably assent to it. But suffices how?

This fundamental issue was not clear in "Analyticity." I got a lot clearer about it in my (2003b) and subsequently. Once the issue is clarified, it becomes much harder to see exactly how explanations in terms of epistemic analyticity are supposed to work, even while it continues to look extremely plausible that at least some of our *a priori* knowledge should be explained in this way.

Broadly speaking, there are two very different routes from grasp to justifiable assent, depending on how we think about the relation between grasp and assent. On one way of thinking about it,

(Constitutive)
Grasp of S's meaning is in part *constituted* by a disposition to assent to S.

On an alternative way of thinking about it,

(Basis)
Grasp of S's meaning is constituted by something distinct from the disposition to assent to S but provides a potential *epistemic basis* for the disposition to assent.

The former, *Constitutive*, option in effect construes the understanding of a given sentence in *conceptual role* terms. To grasp S's meaning is to be disposed to assent to S under certain conditions, or to be prepared to make certain inferences involving S.

For example, one influential view has it that for you to mean *conjunction* by 'and' you must be prepared to infer according to (4) and in general from any sentence of the form 'A and B' to 'A.' Similarly, to understand (1) you must be prepared to assent to it.

On the alternative Basis view, grasp of p is distinct from any disposition to assent to p, and so can serve, and sometimes does serve, as the epistemic basis for assenting to p.

The Constitutive View

Let me begin with the first option, the Constitutive view. One limitation of such a view is that a conceptual role semantics, viewed simply as a theory of meaning, has always seemed most plausible in the case of the logical constants, and perhaps also of theoretical terms, but not so much in application to other concepts. If this is right, then the Constitutive view will have limited application.

Williamson (2003; 2007; 2012) has denied that it is plausible as a theory of meaning in even the most favorable cases. He denies that there are any constitutive understanding-assent links.

I don't believe that Williamson's case against the very existence of such constitutive understanding-assent links succeeds; but I won't argue for that here (see my 2012).

However, I do agree that a conceptual role semantics is not plausible for many types of concept – in particular, for color concepts or moral concepts.

More importantly for our purposes, even in those cases where a disposition to assent is plausible as a theory of grasp, it's not at all clear why the grasp-constituting dispositions come out *justified* as a mere consequence of the fact that they are grasp-constituting.

It is tempting to think otherwise (a fact to which I can attest). Suppose that my possessing the concept *and* is constituted in part by my disposition to infer from 'A and B' to 'A.' It's tempting to think that I'm justified in making such an inference merely because it is constitutive of my possession of the concept *and*.

But how is that supposed to work? Is any disposition that is built into the possession of a given concept thereby justified? My (2003a) presented a series of counter-examples to such a generalized meaning-justification connection, and proposed a much more restricted

principle bridging concept grasp and justification. A number of critics (see, for example, Schechter and Enoch, 2006) have highlighted various problems for my proposal.

But the consideration that turned me decisively against Constitutive accounts was one that I had been dimly aware of all along, but which I hadn't confronted properly, and it's this: Even if we got a bridge principle that returned the right verdicts on particular cases, the resultant account of epistemic justification would still be irretrievably *externalist*, since it won't in general be introspectively accessible to the subject which of his dispositions is concept constituting. And I reject externalist accounts of epistemic justification on the grounds that they distort the essentially normative character of the notion of justification.[5]

To summarize: There are three large problems for a Constitutive version of an epistemic analyticity account of *a priori* justification.

- Conceptual role theories are plausible only for a limited range of concepts.
- It's not clear that there is a plausible meaning-justification connection that is extensionally correct.
- Any such connection looks to deliver only an externalist justification for the disposition to assent, one that would be opaque to the subject.

The Basis View

Do *Basis* accounts fare any better?

On a Basis account, the understanding of p is constituted somehow or other, the crucial point being that, since it is not constituted by facts involving assent to p, it can serve as an *epistemic basis* for assent to p.

Of course, we have neither a settled view of understanding, nor a settled view of what an epistemic basis is – and these facts make it hard to flesh out such an account in the requisite detail. We can be confident, though, that both of these notions are in good standing, being needed quite generally, beyond the context of our immediate concerns.

What we are not entitled to be confident about, however, is that when we finally do get satisfying accounts of grasp and basis, it will be clear how grasp of a proposition p could serve as an *epistemic basis* for assent to p.

When I base my belief that the cat is on the mat on my experience of the cat's being on the mat, my grasp enables me to think the relevant thought assent to which I then base on my sensory experience. But what would it be for the grasp itself to be my basis?

There is one instance of this sort of basing that we may be said to understand reasonably well. And that is when my grasp of p consists in my grasp of some sort of explicit definition for p; and my basis for assenting to p consists in my inferring p from its definition (Frege-analyticity).

But this is clearly a very special case – special both in that grasp rarely consists in grasping an *explicit definition*, and in that basis rarely means *inferential basis*.

But if the relation between grasp and assent is not like that, what else could it be like?

The only other model that we have for something's serving as an epistemic basis for a belief is that which obtains between the perceptual state that p and assent to p. But how could the relation between grasp and assent be analogous to the relation that obtains in this case?

A perceptual state can serve as an epistemic basis for assent because it is a *presentation* of the world as being a certain way, a *seeming* – that's essential to its ability to rationalize belief.[6]

But it is hard to see how the grasp of the meaning of a sentence could be a presentation of anything.

Setting this problem to one side, there is another difficulty that any Basis account must confront. If the relation between understanding and the disposition to assent is contingent, as the Basis account would have it, then it is presumably *possible* for someone to understand p perfectly well and yet, even after extended reflection, refuse to assent to p. For example, most people who understand

(5) Anyone who knows p believes p

assent to it. However, some experts on knowledge, who understand (5) perfectly well, refuse to assent to it. They assent to its negation (Williamson's example). On the Constitutivist account, according to which assent is constitutive of understanding, this refusal would impugn the claim that these experts understand (5) perfectly well. But no such conclusion follows on a Basis account.

How, though, on the Basis account, are we to explain why those who affirm (5) are justified on the basis of their understanding of (5), whereas those who deny (5) are not? By hypothesis, both groups understand (5) perfectly well.[7,8]

Conclusion

There has always seemed something right about epistemic analyticity – intuitively, some *a priori* justification derives from our competence with the relevant concepts or meanings.

But it has become increasingly clear that not all *a priori* justification can be explained in this way. The domain of the normative poses an especially important challenge.

Furthermore, even in those cases where an explanation in terms of the epistemically analytic seems most promising, the exact mechanism by which justification for assent may be generated by the understanding alone seems obscure and ill understood.

All of this has made me take the classical project of explaining the *a priori* in part by appeal to the rationalist notion of 'intuition' much more seriously than I had previously been inclined to do (see Boghossian, 2016; forthcoming). Needless to say, much difficult work lies ahead.

Notes

1 Boghossian (1997). A somewhat abbreviated version of the paper appeared as Boghossian (1996).

2 For the most part, I will take sentences to be the bearers of analytic truth or falsity. But everything I say can be modified easily to apply to propositions. Furthermore, I will assume a justification-first epistemology and a broadly internalist view of justification; and I will focus on doxastic justification as opposed to propositional justification.

3 For example, the distinction plays a major role in Williamson (2007) and Russell (2008); also of interest are Margolis and Laurence (2001), Horwich (2000), and Glüer (2003).

4 As I explain later on, I am now inclined to look with favor on the suggestion that the missing ingredient is intuition.

5 If I were happy with externalist conceptions of justification, I would be a reliabilist. And in that case, it would be relatively easy to see what to say about the problem of *a priori* justification.

6 Bengson (2015) has emphasized the terminology of 'presentation.' Unlike him, though, I think of presentations as equivalent to seemings.
7 This argument originates with Ernest Sosa (2007). However, Sosa doesn't embed his argument, as I think is required for it to make sense, in the framework provided by the distinction between Constitutive and Basis accounts.
8 Here, again, it can seem tempting to think that intuition supplies the missing ingredient.

Rule-Following, Objectivity, and Meaning

BOB HALE

1 Wittgenstein on Meaning, Understanding, and Rules

There is widespread agreement that Wittgenstein advances, in the rule-following sections of *Philosophical Investigations* and *Remarks on the Foundations of Mathematics* (Wittgenstein, 1967, §§138–242; 1978, part VI), considerations that are quite destructive of certain conceptions of meaning, understanding, and rule-following into which we may easily slide when we attempt a general philosophical account of them: that meaning something by a certain expression is a special act or state of mind, accompanying or lying behind writing or speaking; that understanding an expression consists in supplying or adopting an interpretation for it; that following a rule – a rule for the use of a word, say – is a matter of traveling along rails which are already laid down and determine its application in new cases, and so on. And it is equally generally agreed that Wittgenstein's aims, in his discussions of these matters, are not wholly negative and destructive – that he seeks to replace these misconceptions by a better account, armed with which we shall be able to resist the pressures which push us into them: using an expression according to a rule is not founded upon reasons, but that does not mean that there can be no going right (or wrong) in our use of expressions – and the key to understanding how this can be so lies in the idea that to employ an expression with a certain meaning, or according to a rule, is to participate in a custom or practice. It is, in other words, no part of his overall purpose to uphold blanket skeptical conclusions, to the effect that there are no such things as meaning something by a particular expression, as understanding another's words, or as employing an expression according to a rule (or as following a rule of any kind). His aim, rather, seems clearly enough to have been to rid us of badly mistaken pictures of what these things are, and to point us towards a proper, less inflated, conception of them.

This much is, I believe, quite uncontroversial. What is controversial is the *extent* of the destruction wrought by the negative considerations Wittgenstein advances and, consequentially, the exact character of the conception of meaning, understanding,

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

and rule-following – centered on the somewhat elusive ideas of custom and practice – that we may retain in the light of a proper appreciation of their destructive effect. There is, in particular, a sharp opposition between what may be termed 'conservative' readings, which see Wittgenstein as solely concerned to undermine certain seductive misconceptions (McDowell, 1984; Baker and Hacker, 1984a; 1984b; 1985) and count it an error to interpret him as providing support for any skeptical or revisionary theses about meaning and related matters, and more radical ones (Kripke, 1982; Wright, 1980; 1981; 1984b; Carruthers, 1984) which claim to find in his writings grounds for calling into question, in one way or another, what may roughly and provisionally be called the objectivity of meaning.

This exegetical issue will not be pursued here.[1] Even if the conservatives are right, the more skeptical lines of thought which Wittgenstein's discussions have suggested to some thinkers quite certainly merit careful attention in their own right, whether or not they can defensibly be attributed to Wittgenstein, or regarded as drawing out consequences of claims to which he uncontroversially commits himself. It is with two of these more skeptical directions of theorizing that we shall be concerned.

2 Kripke on Rules

Kripke (1982) interprets central sections of *Philosophical Investigations* (§§138–242) as developing a 'skeptical paradox' about meaning. The paradoxical conclusion of the skeptical argument is that there is *no fact about what anyone means by any expression* she uses. Faced with this seemingly outrageous conclusion, we naturally incline to the view that there *must* be something wrong with the argument leading to it: that it relies on some assumption which we can reject, or that it makes some fallacious step. To attempt to sustain this claim is to go for a 'straight solution,' which enables us to maintain that there is, after all, some species of fact in which our meaning what we do by our words consists. But Kripke argues – and takes Wittgenstein to have argued – that there can be no such meaning-constitutive facts: the argument, to be reviewed shortly, proceeds by elimination, that is, it considers the various types of fact that might be supposed to play this constitutive role, and tries to show that they cannot do the job required of them. So Kripke advocates instead a 'skeptical solution,' that is, a response to the paradox which *accepts* the skeptical conclusion but seeks to explain how we can live with it; in particular, how we can rehabilitate talk of meaning without supposing that there are facts in virtue of which meaning ascriptions (such as statements of the form 'S means such-and-such by E') are true or false.

Kripke develops the skeptical argument in terms of one central example. Suppose '$68 + 57 = ?$' is a question I have never explicitly considered. What answer should I give? I shall almost certainly answer '125.' And I shall naturally suppose that this is not only the arithmetically correct answer, but the one I must give, if my answer is to be in accord with what I have all along meant by '+' or 'plus.' It is, I suppose, a fact that when I used '+' before, I meant a certain definite function – one which has, *inter alia,* the value 125 for the arguments 68, 57, and not some other function, which has a different value for those arguments. In particular it is a fact, surely, that I didn't mean the function Kripke calls 'quus' (for which we shall use the symbol '$\oplus$'), where $m \oplus n = m + n$, provided that $m, n < 57$, but in case m or $n \geq 57$, $m \oplus n = 5$.

Kripke's skeptic maintains that there is no such fact. His argument focuses initially on the claim that '125' is the answer I must give, if I am to be in accord with what I formerly

meant by '+.' Granting, *pro tem*, that there is no problem about my *present* understanding of '+' – that I use it to mean addition – the skeptic presses two questions, one constitutive and one epistemological:

> What makes it the case that up to now I have meant addition rather than, say, quaddition by '+,' so that '125' is the answer I should give to '68 + 57 = ?,' if I am to be in agreement with what I meant by my previous uses of '+'?
> What justifies me in thinking that this is the answer I ought to return, if I am to be in agreement with my past meaning for '+'?

It is crucially important to note that these questions are posed against the background of an idealizing assumption about my cognitive powers. I am assumed to have perfect recall of all potentially relevant aspects of my past linguistic and non-linguistic behavior, and of all my preceding mental life, any previous thoughts, imaginings, or the like, which may have accompanied my previous uses of '+.' It should be noted also that there is to be no prior restriction upon the type of fact that may be admissibly cited as constitutive of meaning; in particular, there is no Quinean restriction to purely physical or behavioral facts. This idealization sets Kripke's skeptic apart from the traditional variety of epistemological skeptic: if, even under the idealizing assumption, it proves impossible to justify the claim that I meant addition, the conclusion to be drawn is not – with the traditional skeptic – that whilst there may be a determinate fact about what I meant, it lies beyond our epistemic reach, but that there simply is no such fact at all (see Kripke, 1982, pp. 14–15; Wright, 1984a, pp. 762–763; Boghossian, 1989, p. 515).

The skeptic's answer to both questions is, of course: 'Nothing.' By hypothesis, I have never confronted this particular addition problem before, so that the answer I should now give is not settled by my having previously had the explicit thought, or forming the explicit intention, to answer this question by '125.' Furthermore, my past applications of '+' are finite in number, and it is clearly consistent with my past answers to questions of the form 'm + n = ?' that I meant some other function by '+' (such as $\oplus$), which coincides with addition over the cases actually encountered, but diverges from it over '68 + 57 = ?' No finite selection of answers determines to within uniqueness what rule (if any) I was following. The skeptic then argues that no state or event in consciousness – no previous thoughts or imaginings, nor even a special experience of meaning – can constitute the needed fact. First, it is obviously questionable whether there is in fact any single conscious state or event which invariably accompanied my previous uses. Second – and more important – even if there had been, this would be powerless to settle the question unless that state or event in consciousness were itself insusceptible of alternative, quus-like interpretations. In particular, if any past state of consciousness is to prescribe answers in particular as-yet-unencountered cases, it would have to possess a *general* content – a distinctive feeling or mental picture won't do, because it will never be transparent what that requires of me in new cases; rather, it would have to be something like a general thought, such as that the answer I should give to any question of the type 'm + n = ?' is the one which I obtain by counting a collection of m marbles, say, and then a disjoint collection of n marbles, and finally counting the union of these two collections. But this gets us nowhere, unless we assume that there is no parallel problem about what I meant by the terms in which the general rule was formulated. We are just assuming that by 'count' I formerly meant what I now mean by that word, and did not mean *quount*, where quounting the union of two sets gives the same

answer as counting them, provided that neither of the sub-collections has more than 56 elements; otherwise, the result of the quount is to be '5.' Keeping this perverse interpretation in play may need further perverse hypotheses about what I meant by such terms as 'union,' 'subset,' or 'co-extensive.' But there is no evident reason to think they can't be conjured up, with a little ingenuity.[2]

In effect, Kripke's point here is that sooner or later we are going to have to deal with the situation where I am supposed to have attached a certain definite meaning to certain words without giving myself an explanation of them, or rules for applying them, in general terms – so we may as well just suppose that '+' is such.

The thought is tempting that our failure to locate a meaning-constituting fact in the details of my past applications of '+,' or in the conscious states or events which may be supposed to have accompanied them, results from our looking in the wrong place, for a fact of the wrong sort. My meaning one thing rather than another by my words consists, it may be supposed, in my being *disposed* to apply them in certain ways and not in others. The attraction of this suggestion is that it can be a perfectly good fact that I was disposed to do certain things, not others, even though I did not actually do them – for the circumstances appropriate to exercise of the disposition need not have presented themselves. In particular, it could be that I was all along disposed to answer '125' to the question '57+ 68 = ?' but never actually did so, simply because no events occurred to trigger my additive disposition in this particular way. But the dispositional proposal must be rejected, Kripke argues, for two reasons. First, although it may at first appear that linguistic dispositions have the requisite generality, this is an illusion. There are potentially infinitely many questions of the form 'm + n = ?' but it just isn't true – or so Kripke claims – that for each and every one of them I was disposed to give a certain definite answer. We can only speak correctly of my being disposed to answer this way rather than that, when the numbers to be added are not too big for me to add. In this sense, our dispositions are *finite*. But this means that the dispositional 'solution' doesn't overcome the problem about the finiteness of actual past uses, for the class of answers I did give *or would have given* is still finite; and the skeptic can then undercut the proposed solution by choosing his example so that it lies beyond the reach of my additive (quadditive?) dispositions (Kripke, 1982, pp. 26–28). Second, the dispositional proposal fails to capture the essentially *normative* aspect of meaning. I may well be disposed to make certain sorts of mistake when doing addition. If what I meant by '+' is identified with what I was disposed to say, in answer to '+' questions, then there is no room for a needed contrast between the answers I *would* have given and those which I *should* have given, the latter being those which accord with my past meaning for '+.' Generally, the claim that some expression means such-and-such has a normative component – it is a claim about the circumstances in which it is, or would be, correct to apply it – which evades capture by an attempted reduction of (putative) meaning-constitutive facts to dispositional facts (Kripke, 1982, pp. 28–32).

Taking it that the alternatives considered and rejected exhaust the possibilities, Kripke's skeptic concludes that there is no fact constitutive of my *having meant* + rather than ⊕ by '+' in the past, and nothing that could justify my conviction that '125' is the answer I should now give to '68 + 57 = ?' if I am to be faithful to my past meaning for '+.' Furthermore, the conclusion appears to admit of straightforward generalization: if there were a fact in virtue of which I *now* mean + by '+,' then – under the idealizing assumption of perfect recall, and so on – I would be able to cite this fact to rebut *tomorrow's* skeptical questions. But I shall clearly be no better placed tomorrow than I am *today*, so there is no such fact.

And clearly enough, the skeptical argument doesn't essentially concern me, or the sign '+,' so it applies to all other language users and all other expressions. We have the skeptical paradox in full generality: "There can be no such thing as meaning anything by any word. Each new application we make is a leap in the dark; any present intention could be interpreted so as to accord with anything we may choose to do" (Kripke, 1982, p. 55).

Kripke's Wittgenstein commends a skeptical solution. The first part of the skeptical solution agrees with the skeptic that there are no facts described or misdescribed by meaning-ascriptions, but says: that doesn't matter, because such statements are *not aimed at stating facts*, but have a quite different, non-fact-stating role. Kripke seeks to make plausible his attribution of this idea to Wittgenstein by linking it to Wittgenstein's abandonment of the truth-conditional theory of meaning found in his *Tractatus* in favor of the conception of meaning as use advocated in his later writings, according to which an account of the use of a declarative sentence will comprise, in Kripke's view, a description of the conditions in which it may be appropriately asserted, together with an explanation of its role in surrounding linguistic and non-linguistic practices. The second part of the skeptical solution brings in the community. The conditions in which it is appropriate to say things like 'Jones means addition by "+"' are essentially communal – the remark is appropriately made when we have found that Jones makes statements using '+' which are in good agreement with the things we are ourselves inclined to say. The point and role of such remarks is to acknowledge him as a fully paid-up member of the community of adders, to convey that he can be relied upon not to come up with bizarre answers (like '5') to addition problems (like '68 + 57 = ?'), and so on.

Kripke's Wittgenstein thinks community involvement is essential to provide for the normativity of meaning. If we just consider Jones on his own, all there is is his inclination to apply the word in a certain way (to respond, unhesitatingly but blindly, to addition questions with certain answers); there is nothing for his usage to be in or out of accord with. There is no room, at the level of the isolated individual's use, for the crucial distinction between what *seems* to him right and what *is* right; so that we cannot speak of right at all (cf. Wittgenstein, 1967, §258). It is only when we bring in the community, and with it the possibility of agreement and disagreement between his use and that of the rest of us, that there can be a question of his applying the word rightly in a particular case. It is essential to realize that Kripke's Wittgenstein is not proposing that there is, after all, a fact constituting my meaning + by '+,' but an essentially communal fact: if that were his position, it would clearly be vulnerable to a community-wide version of the skeptical argument, for there would then be no less a problem about what rule the community is following than there is about the individual – there is but a finite stock of previous uses of '+' by the community, and that no more determines what function was meant than does the individual's past usage, and so on.

3 Is Semantic Irrealism Incoherent?

Kripke's argument has, quite justly, received a great deal of critical attention, mostly aimed at making out that the skeptical paradox admits of a straight solution – either one that Kripke overlooks altogether, or one that he considers but fails to rule out. These attempts may be divided into two broad groups. In the first come those which accept the assumption to which, notwithstanding his early insistence that there are to be "no limitations … on the facts that may be cited to answer the sceptic" (Kripke, 1982, p. 14), Kripke himself appears

to subscribe, that putatively meaning-constitutive facts must be specifiable in non-semantic, non-intentional terms. The main contenders here – aimed at a naturalistic solution – have been attempts to uphold some more or less sophisticated version of dispositional theory, or to show that a broadly causal account of meaning and/or reference escapes the skeptical argument. It has also been claimed that even if Kripke's objections are effective against a dispositional account, they do not dispose of the view that an expression's having a certain meaning consists in its being associated with an appropriate capacity.[3] Others – the second group – take issue with what they see as a substantial reductionist assumption underpinning the skeptical argument, and have accordingly sought to defend the view that semantic facts, or closely related facts about intentions, need not be reducible to facts of some other, naturalistic kind.[4]

Kripke himself describes the skeptical conclusion as "insane and intolerable" (Kripke, 1982, p. 60). But he believes that it is nonetheless a conclusion we have to accept. The skeptical solution, he hopes, enables us to do so. Others have taken a less optimistic view of the skeptical solution, arguing that the skeptical conclusion not only appears to be but really is intolerable. If they are right then there must be something wrong with the argument to it: a straight solution of some sort must be possible. Space does not permit detailed evaluation of the various alternatives which have been canvassed here. In this section I shall, instead, examine some arguments designed to establish the incoherence of the position to which Kripke is led by the skeptical argument. First, however, it will be useful to make some remarks about what that position – semantic irrealism, as I shall call it – involves.

Meaning-statements are made by means of declarative sentences. As such, they may be asserted on their own, and they may equally figure as components in conditionals, disjunctions, and other compounds. This is, arguably, by itself enough to ensure that they may with equal propriety be embedded in such contexts as 'It is true that …' and 'That … is a fact.' It might perhaps be insisted that such embeddings are acceptable only if the embedded sentences express claims which are subject to standards of correctness. I am not myself convinced that that is so, but even if it is, a proponent of the skeptical solution could hardly object on that score to our saying, for example, 'That Jones means addition by "plus" is a fact.' The aim of the skeptical solution is to rehabilitate (talk of) meaning in the face of the skeptical conclusion, by explaining how we can properly and correctly assert things like 'Jones means addition by "plus."' There is no unavoidable error in ordinary talk of this kind – Kripke is not advocating an 'error theory' of meaning discourse, analogous to John Mackie's error theory of ethical discourse (see Chapter 20, REALISM AND ITS OPPOSITIONS, §4): the error lies, rather, in prevalent philosophical (mis)interpretations, which construe meaning-statements as genuinely fact-stating or descriptive, having genuine truth-conditions.

It is, then, an obvious thought that for this very reason, it cannot be right simply to deny without qualification that meaning-statements are ever true, or that they state facts. Kripke anticipates such an objection to the skeptical solution's endorsement of the skeptical conclusion, and suggests that it may be defused by appeal to the 'redundancy' theory of truth (Kripke, 1982, p. 86. See Chapter 21, THEORIES OF TRUTH, §8). His thought seems to be that, since 'it is true that S means that p' has the same content as 'S means that p,' we are doing no more in asserting the former than we are in asserting the latter, and so are saying nothing from which a proponent of the skeptical solution need dissent. But this is puzzling.[5] In fact, the point seems to tell in precisely the opposite direction: just because, given a redundancy or deflationary conception of truth (and facts), 'It is true (is a fact) that S means that p' says no more than 'S means that p,' there can be nothing wrong with the former – and

accordingly, if the skeptical denial that meaning-statements are true or state facts is understood as involving this minimal notion of truth or fact, it must be wrong. The moral – apparently not clearly appreciated by Kripke – is that the skeptical conclusion, if it is to have even a chance of being acceptable, must be understood as invoking some more substantial conception of truth and facts. And if the skeptical solution is to have point, clarification of the more substantial notion(s) of truth and fact whose application to meaning-statements is to be denied becomes a matter of some urgency.[6] Whether a telling objection to Kripke can be erected around this point will be considered later. Meanwhile, I shall reserve the term 'true' for whatever more substantial notion might be taken to be in play, and employ 'correct' for the minimal sense. The skeptical conclusion can then be understood as claiming that meaning-statements are *never true*, but are (at best) *correct*.

More than one thinker has remarked upon the close similarity between the skeptical solution's combination of meaning irrealism with an attempt to rehabilitate meaning discourse by construing it non-descriptively, and more familiar projectivist attempts to save our thought and talk in other areas, such as morality, aesthetics, and modality, where the apparent absence of a suitable range of truth-conferring facts seems to preclude a fully realist construal of the discourse (cf. Wright, 1984b; Boghossian, 1989; 1990). And in one way, given the essentially normative character of the notion of meaning – on which all parties are agreed – together with the plausible claim that there can be no successful reduction of the normative to the purely factual, it may seem that meaning discourse is ripe for projectivist reconstruction (see Chapter 20, REALISM AND ITS OPPOSITIONS, §4). On the other hand, just because a projectivist treatment of some given region of discourse is a thesis about the kind of meaning attaching to statements belonging to it, it may be doubted whether a non-factualist or projectivist approach can coherently be applied to meaning itself. It may well seem that the philosophical point and advantage of, say, a projective treatment of ethical discourse (perhaps based upon the kind of expressivist reconstrual proposed by the emotive theory) would be substantially compromised, if coupled with the thesis that meaning discourse quite generally, and so any claim about the sort of meaning possessed by ethical statements in particular, is itself not genuinely factual but projective of, say, some attitude we have. These are, of course, no more than vague misgivings. Can they be transformed into a sharp and telling objection to the skeptical solution?

John McDowell wrote:

> It is natural to suppose that if one says 'There is no fact that could constitute its being the case that P,' one precludes oneself from affirming that P; … Given this supposition, the concession that Kripke says Wittgenstein makes to the sceptic becomes a *denial* that I understand the 'plus' sign to mean one thing rather than another. And now – generalizing the denial – we do seem to have fallen into an abyss: 'the incredible and self-defeating conclusion, that all language is meaningless' (Kripke, 1982, p. 71). It is quite obscure how we could hope to claw ourselves back by manipulating the notion of accredited membership in a linguistic community. (McDowell, 1984, p. 330)

The pessimistic conclusion is, however, too swiftly drawn. As we have seen, it is a condition of the coherence of Kripke's skeptic's argument that he is working with a substantial notion of fact, one for which the correctness of 'It is a fact that P' is precisely *not* guaranteed merely by the assertibility of 'P': that is, a more than merely deflationary or minimal notion of fact. But for this notion we can hardly expect there to be a generally unproblematic transition from 'It is not a fact that P' to denying that P. Kripke will want to hold, on the contrary, that there will be cases in which we can correctly assert that P, when it is not a fact that P. McDowell's

'natural supposition' just begs the question against him. It may be that irrealism about meaning, in contrast with irrealist theses in other areas, such as morals or mathematics, will turn out to suffer from some distinctive species of instability. But if so, further argument is needed to disclose it. Important arguments to the purpose have been advanced by Wright and Boghossian (cf. Wright, 1984a; Boghossian, 1989; 1990).

Wright argues in two stages: (1) irrealism about meaning leads to global irrealism and (2) global irrealism is incoherent or otherwise directly objectionable. Wright's globalizing argument pivots on what he calls the meaning-truth platitude, that 'the truth value of a statement depends only upon its meaning and the state of the world in relevant respects.' In its original version, from which this formulation of the platitude is taken, it runs thus:

> If the truth value of S is determined by its meaning and the state of the world in relevant respects, then non-factuality in one of the determinants can be expected to induce non-factuality in the outcome. (A rough parallel: If among the determinants of whether it is worth while going to see a certain exhibition is how well presented the leading exhibits are, then, if questions of good presentation are not considered to be entirely factual, neither is the matter of whether it is worth while going to see the exhibition.) A projectivist view of meaning is thus, it appears, going to enjoin a projectivist view of what it is for a statement to be true. Whence, unless it is, mysteriously, possible for a projective statement to sustain a biconditional with a genuinely factual statement, the disquotational schema '|P| is true if and only if P' will churn out the result that *all* statements are projective. (Wright, 1984a, p. 769)

Against global projectivism Wright advances several related but distinguishable considerations. An obvious worry, hinted at previously, is that a projectivist treatment of any particular class of statements has point only in so far as it draws a significant contrast between members of that class and other statements which are to be viewed as genuinely fact-stating, or apt for substantial truth. Relatedly, whilst a perfectly good distinction may *turn out* to be empty on one side, it may be doubted whether that could be an *a priori* matter, as would be the case with the needed distinction between fact-stating and non-fact-stating discourse if the globalizing argument is sound. Third, supposing the distinction satisfactorily drawn, the projectivist will surely want to regard it as a *discovery* that statements in the target class are non-factual – in particular, shouldn't the statement of the conclusion of the skeptical argument be *itself* genuinely factual? Fourth: there will be no *truths* about the (Kripkean) assertion conditions of any sentences, with the result that the premises of Kripke's version of the argument against private language (relating to the communally oriented character of the assertion conditions of meaning-statements), and hence also its conclusion, will enjoy a merely projective character (Wright, 1984a, pp. 769–770).

Boghossian agrees with Wright that irrealism about meaning inflates into global irrealism (though he gives a somewhat different argument for this claim), but he is not persuaded that this is intrinsically objectionable; instead, he argues that meaning irrealism leads directly to self-contradiction, independently of its implicitly global character. The argument[7] starts from a generalization of the point made above: that since any significant, declarative sentence is apt for truth in a merely deflationary sense, a non-factualist thesis about any class of statements cannot be understood as denying that any of those statements are true in that sense, but must be taken to involve a richer, more substantial notion of truth. The non-factualist is, as he puts it, "committed to holding that the predicate 'true' stands for some sort of language-independent property, eligibility for which will not be certified purely by the fact

that a sentence is declarative and significant" (Boghossian, 1989, p. 526). He then claims that a judgment that some sentence is or is not (substantially) true cannot but be a genuinely factual judgment. That is: the judgment that S is true (and likewise the judgment that S is not true) must itself be true or false, as opposed to being merely correct or incorrect. But the meaning non-factualist's distinctive thesis is that judgments about what a sentence means are not factual. Since what truth-condition a sentence possesses is a function of its meaning, it follows that judgments about what truth-condition a sentence has are likewise not factual. And since a sentence's having a particular truth-value cannot be a factual matter if its having a certain truth-condition is not, it further follows that a judgment about a sentence's truth-value can never be factual. Thus the meaning non-factualist is committed to denying that it is ever true that S is true. His position is thus self-contradictory.

Does either of these arguments succeed? Obviously enough, the crucial claim in Boghossian's argument is that the judgment that a sentence is (substantially) true must itself be genuinely factual. But it is anything but obvious that the meaning non-factualist must agree. He is, as we have seen, committed to the intelligibility of a thick (that is, more than merely deflationary) notion of truth; though whether he is further committed to its having a non-empty extension must, at this stage, be regarded as an open question. But acceptance of that much seems perfectly consistent with retention of the thin, merely deflationary notion which we are calling correctness. And so long as both notions are available, why can't the non-factualist hold, apparently with perfect consistency, that metalinguistic attributions of truth, falsity, correctness, and incorrectness are all alike, at most correct and never true? Boghossian believes that the non-factualist has not merely to make room for a thick (or as he says 'robust') notion of truth, but that he must *choose* between that and a purely deflationary one:

> It is an assumption of the present paper that the concept of truth is *univocal*… We should not confuse the fact that it is now an open question whether truth is robust or deflationary for the claim that it can be both. There is no discernible plausibility in the suggestion that the concept of a correspondence between language and world and the concept of a language-bound operator of semantic ascent might both be versions of the same idea. (Boghossian, 1990, p. 165, n. 17)

Clearly so crucial an assumption stands very much in need of supporting argument; surprisingly, Boghossian provides none, unless you think that the last sentence quoted does more than merely reassert what needs to be established.

This objection coincides pretty well, I think, with one of several developed in more detail by Wright (cf. Wright, 1992a, p. 234; 1993, pp. 318–324), who insists, as I have done, that the non-factualist is free to wield notions both of truth and correctness. Somewhat ironically, this distinction appears at first to provide the non-factualist with a ready way to interrupt Wright's own attempted *reductio* at the first, globalizing stage. As Wright's formulation makes plain, the final step involves an application of the Disquotation Scheme for 'true.' More specifically, he appears to have envisaged substituting the right- for the left-hand side of the scheme, to get from:

> '"P" is true' is not true

to

> 'P' is not true

But it now appears that the non-factualist may block this step: when 'P' is true, '"P" is true' will be merely correct, so that the Disquotation Scheme – 'P' is true if and only if P – fails right-to-left.

In fact, this claim relies upon a questionable assumption about the evaluation of conditionals, that is, that a conditional will hold (be true, or at least correct) only if there is no descent in value (from true to correct, say) between its antecedent and consequent. As against this, it may plausibly be claimed that we should require only preservation of designated value (where true and correct are designated, the remaining values not). However, whilst this makes it at least doubtful that the non-factualist can block the globalizing argument by rejecting the Disquotation Scheme outright, it leaves him with the resources for an equally effective rejoinder – indeed, a more satisfactory one, because it allows him to retain the Disquotation Scheme. For if the scheme is secured by adoption of the proposal that what is required for a conditional to hold is not that the consequent is true if the antecedent is, but only that designated values shall be preserved, then instances of the biconditional scheme will not support substitution of their components in complex contexts such as that involved in the globalizing argument.[8]

There is another, more obvious ground for dissatisfaction with the globalizing argument, at least in Wright's version. For it seems clear that, at least as formulated, the argument given works at best for a sense of 'statement' in which statements can be taken as *both* bearers of meaning *and* bearers of truth-value. A proponent of semantic irrealism need not deny that there is, or could be, such a sense of 'statement,' provided that he is granted a different sense in which statements have truth-values, but cannot sensibly be said to have meanings. Concerning any statement in this sense, he can claim that whether or not it is true *is* a factual matter; or more precisely, that its being so is not threatened by the non-factuality of meaning. It is true enough that whether or not a particular *sentence* is suitable for making a particular statement in this sense depends upon the sentence's having a certain meaning – and that, he holds, is not a factual matter. But the truth-value of a statement, in his preferred sense, does not depend upon the meaning of anything. It does not depend upon the meaning of the *statement*, because statements are not the sort of thing to have meanings; and it does not depend upon the meaning of a certain *sentence* – what depends upon a sentence's meaning being, rather, what statement(s) that sentence can be used to make. Thus non-factuality at the level of meaning does not induce non-factuality at the level of truth-value of statements.[9]

This discussion has inevitably been somewhat inconclusive. If what I have argued is right, it has not been shown that irrealism about meaning leads directly to contradiction, independently of its putative tendency to inflate into global irrealism; and it is at least open to question that it does globalize. And even if it does globalize in the way Wright and Boghossian both believe, it remains to be seen whether that leads to its collapse. Wright's arguments are suggestive of instability here, but appear less than decisive.

4 Wright on the Rule-Following Considerations

4.1 The Contractual Model of Meaning and Investigation-Independence

While Wright is sharply opposed to the semantic-irrealist conclusion which Kripke extracts from the rule-following considerations, he advances (Wright, 1980; 1981; 1984b) an argument (for which he claims Wittgensteinian origins) whose conclusion has – rightly or

wrongly – been seen as carrying implications for the notion of objectivity which are scarcely less radical, and no more palatable, than Kripke's. The argument is directed not at calling in question the very existence of facts about meaning, but at undermining what Wright takes to be an important misconception of their character. According to the conception under attack – the contractual model of meaning[10] – an expression's having a certain settled meaning consists in its being associated with a definite pattern of application which, once established, extends 'of itself' to new cases quite without any further assistance from us. Learning what the expression means is a matter of 'cottoning on' to such a pattern; our subsequent employment of the expression then either conforms, or fails to conform, with requirements already laid down, as it were, in the contract to which we have become party. Wright's contention is that, for reasons implicit in Wittgenstein's discussions of rule-following, the contractual model is fundamentally flawed and must be replaced by a conception of meaning as shaped by our ongoing use.

That is the immediate conclusion of Wright's argument. If for no other reason, the argument which purports to establish it deserves the closest scrutiny simply because the contractual picture is one which we may find both appealing and entirely natural, and which may, indeed, seem inevitable when we seek to understand what is involved in the normativity of meaning, so that Wright's conclusion is at the very least unsettling. But Wright draws a further conclusion which may appear not merely unsettling, but plainly intolerable. This concerns the way or sense in which ordinary factual statements may be held to be objectively true or false. What, in very general terms, we intend when we take a statement to be objectively true or false, is that its truth-value is in some way independent of our, or anyone else's, opinion. But this somewhat vague idea can be cashed out in various more specific ways. We ought not to be surprised if it should prove that what more precise characterization of it is found acceptable depends upon where one's sympathies lie in the dispute between realists and anti-realists in the theory of meaning (see Chapter 20, REALISM AND ITS OPPOSITIONS, §§1 and 2). Wright focuses upon one particular conception of objectivity – *investigation-independence* – which we might expect anyone of a realist persuasion to endorse. A realist, in Dummett's sense, about a certain class of statements – that is, one who holds that statements in that class are such that their truth-conditions may be fulfilled, or not, without our being even in principle capable of recognizing as much – evidently regards those statements as objectively true or false. But if a capacity for evidence-transcendent truth is taken as the criterion, the resultant sense of objectivity is very strong indeed. By their very nature, no effectively decidable statements will qualify as having objective truth-values in this sense. And the same, it is natural to suppose, goes for very many other perfectly ordinary statements which, though not effectively decidable in any strict sense, would normally be viewed as capable of objective truth. Assuming that the realist wishes to regard statements of these latter kinds as capable of objective truth, what alternative criterion should he adopt? Wright's plausible suggestion (cf. Wright, 1981, p. 99) is that he will embrace a notion according to which "confronted with any decidable, objective issue, there is *already* an answer which, if we investigate the matter fully and correctly, we will arrive at." For such statements, that is, objectivity of truth-value consists in the possession of a determinate, *investigation-independent* truth-value. But investigation-independence, Wright argues, requires the contractual model of meaning:

> Investigation-independence requires a certain stability in our understanding of our concepts. To think, for example, of the shape of some particular unobserved object as determinate, irrespective

> of whether or not we ever inspect it, is to accept that there are facts about how we will, or would, assess its shape if we do, or did, so correctly, in accordance with the meaning of the expressions in our vocabulary of shapes; the putative investigation-independent fact about the object's shape is a fact about how we would describe it if on the relevant occasion we continued to use germane expressions in what we regard as the correct way … The idea of investigation-independence thus leads us to look upon grasp of the meaning of an expression as grasp of a general pattern of use, conformity to which requires certain determinate uses in so far unconsidered cases. The pattern is thus to be thought of as extending of itself to cases which we have yet to confront. (Wright, 1981, p. 100)

If this is correct, a successful argument against the contractual model will be equally destructive of the idea that statements are capable of objective truth-value in the sense captured by investigation-independence.

It is obvious that any statement which is evidence-transcendently true or false will be objectively true or false in the sense captured by investigation-independence, but that the converse does not hold. In that sense, the latter is a weaker notion of objectivity than the former. And this, coupled with the fact that the notion of evidence-transcendent truth plays no part in the characterization of the weaker notion, might suggest that someone who rejects realism in Dummett's sense could endorse the claim that there are investigation-independent truths. But if Wright's argument is sound, this is an illusion. For the argument, as we shall see, makes essential use of an anti-realist premise, so that if he is unable to find fault with it elsewhere, the anti-realist must reject the notion of investigation-independent truth.

4.2 The 1980/1981 Argument

Can an individual speaker S, in her use of an expression E, defensibly be regarded as attempting to conform to a pattern of application, the requirements of which are already in place? Wright's argument, in its earlier version, divides the question into two.

First, can we defensibly regard S as aiming at conformity to such a pattern *independently* of the possibility of assessment of her performance by others?[11] The difficulty here is to see how it can be justified to describe the situation in terms of S's *recognizing* what her supposed pattern requires her to say, in any particular case, as opposed to her merely being *disposed* to apply E (or not, as may be). The former description is justified only if there is a distinction to be drawn between S's going on as the pattern demands on the one hand, and on the other her merely *seeming* to do so. But S cannot make this distinction for herself, since it is bound to seem to her that her sincere and considered application of E conforms to the requirements of the pattern; and by hypothesis, the distinction is not to be made out on the basis of others' assessment of her performance.

Since the contractual picture cannot be sustained for this case, we move to the question of whether it can make a difference to the situation if we add in, as it were, facts about the agreement, or lack of it, between S and the rest of us over the application of E. Wright argues that it makes no essential difference. Here it is crucial to remember that the question at issue is not whether agreement with the community somehow provides the standard of correctness, but whether bringing in agreement, or lack of agreement, with the community affords a way of keeping the contractual picture in play. As Wright puts it, it is the question: "How does others' agreement with me turn my descriptive disposition into a matter of recognition of conformity with a pattern, recognition of an

antecedent fact about how the communal pattern extends to the new case?" (Wright, 1981, p. 103). The answer, unstated but clearly implied, is that it cannot do so.

Wright restates this last part of the argument in a somewhat different way, which is worth noticing because it corresponds rather more closely to his later, and much terser, formulation (in Wright, 1984b). If S's agreement with the rest of us somehow made the crucial difference, so that she could be thought of as recognizing what the shared pattern dictates in a given case, then it should at least make sense for her to claim, should she find herself at loggerheads with the rest of us over the application of E, to recognize that we have gone off track. But the only proper conclusion for S to draw, given that she can find no way to persuade us that we have broken faith with our antecedent pattern, is – or so Wright contends – that she does not (and perhaps never did) know what E means (as we employ it). But if no one can recognize that the community has *gone off* the rails, no one can recognize that the community has *stayed on* them; mere lack of disagreement with the community cannot substantiate the claim to recognize what its supposed pattern requires.

It is tempting, as Wright notes, to think that "a solicitable community of assent just does make the relevant difference" (Wright, 1981, p. 104). But he gives a supplementary argument (cf. Wright, 1980, pp. 219–220) which, if good, shows that the temptation must be resisted. On the contractual model, the bearing of communal agreement over the application of E on the correctness or otherwise of S's use has to be understood in a quite particular way. It is not that communal agreement is *constitutive* of correct use. Correctness must consist in conformity with the requirements of the community's pattern, and communal agreement can be at best[12] good inductive evidence for that. In other words, on the contractual model, a community of assent on what should be said in a given case provides the standard against which individual applications of E are to be assessed *only because and in so far as* communal agreement can be taken to be based upon *recognition* of what the community's shared pattern requires. But once this is seen, it should be clear that we have no progress: so, far from answering the objection previously urged against the picture of individual, community-independent conformity to an antecedent pattern, bringing in the community merely shifts the target. For what now requires justification is description of the situation in terms of the community's *recognizing* what its supposed pattern requires, in any particular case, rather than in terms of its merely being *disposed*, collectively and non-collusively, to apply E (or not, as may be). The former description is justified only if there is a distinction to be drawn between the community's going on as its pattern demands on the one hand, and on the other its merely *seeming* to it that it is doing so. As Wright puts it:

> If 'correctness' means ratification-independent conformity with an antecedent pattern, there is apparent absolutely nothing which we can do to make the contrast active between the *consensus description* and the *correct description*. (Wright, 1980, p. 219, my emphasis)

Of course – and as Wright agrees – we may as a community retrospectively judge that our erstwhile, communally agreed verdict on a particular case was mistaken; but this can give no comfort to the contractualist, since it is obviously wholly tendentious to view this as a matter of our belatedly recognizing that we previously broke faith with the requirements of an antecedently determinate pattern.[13] The necessary contrast between recognizing what our pattern required, and our earlier, collective disposition concerning what to say merely changing, is evidently no less problematic than that between recognizing what our pattern requires us to say now and our present disposition.

Although it will scarcely have escaped the notice of readers already familiar with this debate, it is worth underlining the argument's reliance, in its closing step at least, if not earlier, upon an anti-realist premise to the effect that there is no sense to the claim that we operate with a distinction – in this case between the supposedly ratification-independent requirements of our pattern of use and how we think we should apply the expression in question – if there is nothing we can do to manifest a grasp of it. Wright himself is under no illusions, of course, about the need for such a premise, and indeed, stresses the point:

> If those arguments [i.e., the general anti-realist arguments against the intelligibility of attributing grasp of concepts of which there is no distinctive manifestation] are rejected, then there is … no obstacle to embracing the investigation-independence of decidable statements. If, and only if, one admits the need to describe how an understanding could be *revealed* of what it is for our consensus verdict … to fit the alleged investigation-independent fact of the matter … will one feel pressured to reject the 'double-element' conception. (Wright, 1980, p. 221)

That concludes my summary of Wright's argument in its earlier formulation. It leaves us facing three main questions: (1) Is the argument sound? (2) Is the rejection of investigation-independence it enjoins tolerable? (3) If the contractual model is to be scrapped, what should replace it?

4.3 Horrified Reactions

In view of the apparent innocence of the notion of investigation-independence, it is no surprise that others have seen its rejection not as a salutary corollary of the argument against the contractual model, but as revealing that something must have gone badly wrong, either in the argument Wright builds upon Wittgenstein's discussions of rule-following or in the rule-following considerations themselves. Thus John McDowell writes:

> If Wittgenstein's conclusion, as Wright interprets it, is allowed to stand, the most striking casualty is a familiar notion of objectivity. The idea at risk is the idea of things being thus and so anyway, whether or not we choose to investigate the matter in question, and whatever the outcome of any such investigation. That idea requires the conception of how things could correctly be said to be anyway – whatever, if anything, we go on to say about the matter: and this notion of correctness can only be the notion of how the pattern of application that we grasp, when we come to understand the concept in question, extends, independently of the actual outcome of any investigation, to the relevant case. So if the notion of independent-investigation is to be discarded, then so is the idea that things are, at least sometimes, thus and so anyway, independently of our ratifying the judgement that that is how they are. It seems fair to describe this extremely radical consequence as a kind of idealism.[14]

Although McDowell thinks that we cannot accept Wright's conclusion, and is thus committed to denying the *soundness* of the argument leading to it, he does not dispute its *validity*. In fact, he is committed to its validity, because he takes it to form the core of an effective 'transcendental argument against anti-realism' which reduces to absurdity the anti-realist premise upon which, as we have noted, the argument relies. It would, of course, be wholly tendentious, in the present context, to rest such a *reductio* on the alleged absurdity of the denial of investigation-independence itself. The absurdity lies, rather – or so McDowell contends – in the picture of language to which Wright's argument commits him, on which

there is no room for normativity, and so no room for meaning, at all. Of course, Wright does not himself think that his argument leads to this absurd conclusion. But there is no escaping it, McDowell claims, once we accept with Wright that at the individual level there is no going right or wrong in our use of words save in the context provided by communal assessment of individual use, and that as far as the community as a whole is concerned there is no authority to which its collectively agreed use is answerable, and no distinction to be drawn between the 'consensus description' and the 'correct description,' so that we cannot say that it 'goes right or wrong,' only that it 'just goes.' For this entails a picture of language use on which, 'at the basic level,' human beings are merely 'vocalizing in certain ways in response to objects,' no doubt to the accompaniment of certain 'feelings of constraint, or convictions of the rightness of what they are saying,' but at which 'there is no question of shared commitments – of the behavior … being subject to the authority of anything outside themselves … How, then, can we be entitled to view the behaviour as involving, say, calling things "yellow," rather than a mere brute meaningless sounding off?' And once we are committed to this picture of the 'basic' level, stripped of normativity altogether, there is no hope of reinstating it via the notion that individuals are subject to communal correction. As McDowell puts it,

> The problem for Wright is to distinguish the position he attributes to Wittgenstein from one according to which the possibility of going out of step with our fellows gives us the *illusion* of being subject to norms, and consequently the *illusion* of entertaining and expressing meanings.[15]

This attempt to turn Wright's argument on its head is, it seems to me, a complete failure. McDowell plainly takes it that when Wright observes that there is no standard against which the whole community's practice may be assessed, he is advancing this as his own view. But Wright is doing no such thing; he is himself offering a *reductio* of the idea that correct use is a matter of conformity with a ratification-independent pattern. McDowell appears entirely to have overlooked the crucial point that the conclusion that there is no distinction between the consensus verdict and the correct verdict is drawn on that hypothesis – hence Wright's conditional: 'If "correctness" here means ratification-independent conformity with an antecedent pattern, there is apparent absolutely nothing we can do to make active the contrast between the consensus description and the correct description.' Wright's argument as I understand it is that if communal correctness were a matter of conformity with such a pattern then, unless whether or not the community goes right is to be a verification-transcendent matter, there would have to be a distinction between the community's recognizing what its pattern requires and its merely thinking that it does. Since no content can be assigned to *this* contrast, there can be no content either to the distinction between the consensus verdict and the correct verdict, *on this supposition about what correctness consists in*. Given the obvious unacceptability of the conclusion to which it leads, we should reject that supposition.

Somewhat differently, Michael Dummett, in effect,[16] agrees with Wright that "an unflinching application of Wittgenstein's ideas about rules" leads us to deny that there can be predeterminate, investigation-independent facts; since he finds this conclusion incredible, he concludes that 'the "rule-following considerations" embody a huge mistake.' Wittgenstein was

> right to observe that, for the most fundamental of the rules that we follow, there is nothing *by which* we judge something to be a correct application of them. It certainly does not follow

> from this that, if we never do make such a judgement in some particular instance, there is no specific thing that would have been a correct application: to draw that inference, you need a general internalist premiss, that there is nothing to truth beyond our acknowledgement of truth.[17]

But this premise, Dummett complains, is totally implausible; to appeal to it in this context is simply to beg the question.

Since Dummett is discussing Wittgenstein, and not Wright, it would be unjust to complain of a failure to engage the latter's argument. But it is pertinent to observe that Wright's argument is, on the face of it, an argument of precisely the kind whose possibility Dummett denies, since it manifestly does not appeal to any premise to the effect that there is no more to truth than its being acknowledged.

The immediate reason why Dummett finds the rejection of investigation-independence incredible is that it appears to involve denying, in the case of an elementary calculation, that there is in advance of its being carried out any determinately correct result. Another reason that might be given (to which Dummett attaches great importance, both in the paper from which I have quoted and in earlier writings) is that it appears impossible to account satisfactorily for the value or usefulness of deductive inference without appealing to a distinction between a statement's being true and its being actually verified or recognized as true, and hence, it may seem, without invoking the possibility of investigation-independent truth. Indeed, this may be seen as a special case of a quite general difficulty. For it may seem that if Wright's conclusion stands, nothing approaching justice can be done to the conception we all have of human enquiry in general as a process of *discovery*. These are matters for genuine concern, to which – so far as I have been able to see – nothing in Wright's earlier presentations of the argument speaks. Pending explanation of how it might be alleviated, we have a strong motive for hoping, if not for suspecting, that there is after all a flaw in his argument.

4.4 Wright's Strengthened Argument

In fact, there is a flaw in it. The first part of the argument, aimed at showing that there can be no substance to the idea that an individual speaker is aiming at conformity to a pattern of use *independently* of the possibility of assessment of her performance by others, seems to me compelling. We should also agree that the contractual conception requires the possibility of community-wide (and so of near-community-wide) departure from its pattern for a given expression. But Wright's next claim – that the only conclusion a lone dissenter could properly draw, on finding herself unable to bring the rest of us round, is that she no longer understands the crucial expression, and so cannot be a competent critic of the rest of the community's use – is far from clearly correct. On the contrary, it appears that there is plenty of room for a proponent of the contractual view to resist it. No doubt I should be disconcerted to find the rest of the community lined up against me. But it is far from self-evident that, were this to happen, it must be that I have gone astray, and cannot be that *they* have done so. We can surely envisage circumstances in which the opposite would be the case. It is, for instance, at least conceivable that everyone else has, perhaps as a result of exposure to some insidious form of radiation which I have escaped, suffered eye or brain damage which makes red things look yellow to them, or which has somehow scrambled whatever neural assemblies are associated with their capacity to use color terms. Of course, this supposition is far-fetched; but it appears at least to make sense, and that is all that is required.

Reformulating the argument once again, Wright claims:

> none of us, if he finds himself on his own about a new candidate for φ-ness, *and with no apparent way of bringing the rest of us around*, can sensibly claim to recognize that the community has here broken faith with its antecedent pattern of application for φ; the proper conclusion for him is rather that he has just discovered that he does not know what φ means. (Wright, 1980, p. 218)

The italicized words are evidently crucial, since Wright's claim would clearly be preposterous without them. Even with them, the claim that a charge of community-wide error simply makes no sense would be unwarranted if the key words meant merely that there does not appear to be any way in which the isolated individual can persuade the rest that they have gone wrong. Earlier, Wright speaks of the individual being *incorrigibly* out of line, suggesting that there is, without qualification, no way in which he can bring the community around. But now, it seems to me, we need to be a lot clearer about just what supposition it is that we are being invited to entertain, before we can say what follows. Why is it that he can't do that? Are we also to suppose that the situation is, as it were, symmetrical – so that there is, equally, no way in which the community can bring the individual round to its way of thinking? If so, then unless it is further being assumed that one or other party is the victim of some cognitive malfunction which, however, mysteriously resists exposure, we are in effect being asked to suppose that the individual goes one way and the community the other, without either being cognitively at fault: but then it seems that the supposition effectively begs the key question, of whether or not there is a fact of the matter to be recognized.

Wright agrees that his earlier argument needs reinforcement at this point, and seeks to provide it in the later, refurbished version. This proceeds in two stages, corresponding to a distinction Wright draws between basic statements and others. Very roughly,[18] the former are statements involving only demonstratives together with concepts whose mastery consists in the possession of some appropriate recognitional capacity – concepts for which "competent use standardly presupposes no more than normal sensory capacities and ostensive teaching," such as concepts of color, taste, or pitch. In the first stage, Wright deploys a strengthened version of the argument we have been considering, restricted in scope to basic statements; the second stage then generalizes the conclusion – if basic statements lack objectivity of meaning, so must the remainder. The first-stage argument proceeds, in essentials, as before. But now Wright adds a supplementary argument to close off the gap opened up by the apparent possibility that the lone dissenter is right, the rest of his community having indeed gone astray in their application of basic concepts, perhaps as a result of the deleterious effects of some environmental contaminant upon their capacity to apply them reliably, or for some similar reason. What, in more detail, would it be like, he asks, for there to be available reason to think that everyone (else) had gone astray in their application of basic concepts?

Wright's argument starts from the idea that, if this is a genuine possibility, we should be able to see how a sustainable case could be made for thinking it to have been realized. We may suppose that the lone dissenter can put up a case of this sort: he points to (a) evidence that the rest have been exposed to a certain environmental contaminant and (b) evidence that when others have been exposed to this contaminant in the past their basic judgments of the relevant sort have been distorted. Against such a case, a doubt of the following kind may be raised: the evidence (b) involves the claim that the affected

subjects' basic judgments were distorted, and the basis for this claim is that those judgments were found to be at odds with basic judgments made by others who were not affected. The case assumes that we are warranted in taking it that the judgments made by those who were not affected were indeed correct. But might not those very judgments themselves have been the product of widespread error? Unless and until adequate reason can be provided to discount this possibility, the case the lone dissenter has sought to make is worth nothing. Wright's counter-claim is, in effect, that the possibility could only rationally be discounted by appeal to something like this principle, as being analytic of the notion of basic statement:

> If there is widespread non-collusive agreement on the truth of a basic statement S and there is adequate reason to suppose that the parties to this widespread agreement understand the concepts involved in S, and are functioning normally in normal conditions for exercise of the appropriate recognitional capacities, and there is no further evidence germane to the case, then anyone apprised of all these facts has adequate grounds for regarding S as true. (Wright, 1984b, p. 288)

The snag is that the objectivist about meaning can hardly regard this principle as analytic; on her view, it can be at best a contingent truth, and that will not be enough to see off the challenge. In short, the attempt to sustain the contractual model by appealing to the possibility of widespread communal error opens the doors to skepticism.

I shall not here try to evaluate this argument; Wright has, in my view, made a powerful case which – so far as I know – has yet to receive an effective reply. And if he is right, the case against objectivity of meaning relies, in its final form, on no specifically anti-realist premise. I leave the reader to ponder it, and turn instead to my second main – and by now, pressing – question.

4.5 Investigation-Independence and Objectivity of Judgment

The *term* 'investigation-independent fact' is indeed strongly suggestive of a familiar enough and, for all that it calls for philosophical articulation, seemingly indispensable notion of objectivity; so much so that the suggestion that we should deny that there are any such facts may strike us as the philosophical equivalent of red-rag-waving. I shall try to explain why the bulls should stand their ground.

Preparatory to introducing the notion of *objectivity of judgment* – as distinct from that of objectivity of meaning – Wright says:

> Cognition is *relational*: it is a matter of arriving at true opinions in a manner *sensitive* to states of affairs whose obtaining is somehow independent of one's so arriving. Moreover, such a sensitivity must be conceived as essentially fallible. (Wright, 1984b, p. 281)

Obviously the crucial words here are 'somehow independent.' In what does the independence of cognized states of affairs consist? Part of what is involved, at least, is that in any particular case where a subject S comes to know (and so forms a true opinion) that p, it should be the case that the state of affairs in virtue of which it is true that p does not depend in any way at all on S's coming to believe that p; or, indeed, on S's or anyone else's coming to hold any opinion on the matters in question. That is, we conceive of the relevant state of

affairs as such that its obtaining is consistent with universal ignorance of its doing so. That is one component in the notion of objectivity of judgment, as Wright characterizes it. This is naturally expressed in counterfactual terms: whenever a subject S is properly described as coming to know that p, it would (still) have been the case that p, even if neither S nor anyone else had investigated the matter, or formed any opinion on it. It seems to follow that endorsement of objectivity of judgment for a type of statement entails accepting that there are relevant states of affairs which obtain or not, independently of investigation, in this sense at least: it is the case that p (or not) independently of whether anyone ever did or will carry out an investigation to determine whether or not p (and *a fortiori*, independently of the result of any such investigation, were one (to be) carried out).

Taking in the other component which Wright includes in the idea of objectivity being charted – that is, the essential fallibility of judgment – the objectivist about judgment is committed to there being true claims of this sort:

(1) It is the case that p and it would (still) have been the case that p, even if no one had carried out an investigation to determine whether or not p, and even if someone had carried out an investigation, but one that issued in the verdict that not-p.

How about the case where we are concerned with some decidable, but as yet uninvestigated matter? What kind of claim should the objectivist about judgment make then? Well, suppose the question is whether some large integer *k* is or is not prime. Then the objectivist can say this:

k is either prime or not. If *k* is prime, then even if no one ever investigates, it is prime, and were anyone to investigate but come up with a different answer, she would be mistaken; and if *k* is not prime, then again, even if no one ever investigates, it is not prime, and were anyone to investigate but come up, etc.

Generally, where decidable but as yet uninvestigated matters are in question, the objectivist about judgment may register the sense in which they concern objective states of affairs by asserting an appropriate statement of the form:

(2) Either p or not-p. If p, then even if no one ever investigates, p, and were anyone to investigate but come up with any other answer, she would be wrong; and if not-p, then again, even if no one ever investigates, not-p, and, etc.

The crucial point for present purposes is that counterfactuals of the kind embedded in these claims are precisely *not* counterfactuals about *what expressions it would be (have been) correct to apply in certain circumstances*. As such, they contrast sharply with the kind of counterfactual in terms of which investigation-independence is characterized by Wright – "the [investigation-independent] fact about the object's shape is a fact about how we would describe it if … we continued to use germane expressions in what we regard as the correct way" (Wright, 1980, p. 216).

An objectivist about judgment can assert claims of both kinds of the forms (1) and (2). This marks one clear sense in which he can regard certain statements as being true or false in virtue of states of affairs obtaining, or not, independently of investigation. If that is right,

then we should question McDowell's right to the following transition, integral to the argument by which he persuades himself that a "familiar and intuitive notion of objectivity" requires the contractual conception of meaning:

> The idea at risk is the idea of things being thus and so anyway, whether or not we choose to investigate the matter, and whatever the outcome of any such investigation. That idea requires the conception of how things could correctly be said to be anyway – whatever, if anything, we in fact go on to say about the matter. (McDowell, 1984, p. 325)

For endorsement of conditionals of types (1) and (2) seems quite enough to hit off the idea of objectivity (of things being thus and so anyway …). But those conditionals – at least on the face of it – say nothing about how things could correctly be said to be.

It may be replied that this is a mere artefact of formulation: surely the objectivist ought not to make any bones about accepting these reformulations:

(3) It is true to say that p and it would (still) have been true to say that p, even if no one had carried out an investigation to determine whether or not p, and even if someone had carried out an investigation, but one that issued in the verdict that not-p.

(4) Either it is true to say that p or it is true to say that not-p. If it is true to say that p, then even if no one ever investigates, it is true to say that p; and if it is true to say that not-p, then again, even if no one ever investigates, it is true to say that not-p.

Well, of course he should accept them, since their acceptability is guaranteed by the equivalence of 'p' with 'it is true to say that p.' But the effect of securing McDowell's first transition by appeal to the Equivalence Thesis is simply to put in question the next transition in his argument; that is, from the second sentence, just quoted, to:

> and this notion of correctness can only be the notion of how a pattern of application that we grasp … extends, independently of any investigation, to the relevant case.

This transition would be good if, but only if, we could pass from (3) to:

(5) It is true to say that p and it would (still) have been correct to assert 'p,' even if no one had carried out an investigation to determine whether or not p, and even if someone had carried out an investigation, but one that issued in the verdict that not-p.

or something to that effect. For it is only if some such transition to a (counterfactual) claim about what words it would have been correct to use is allowable that endorsement of objectivity in the sense of the premise can be made out to involve commitment to the idea of a pattern of application (of some words) extending independently of investigation. But it should be quite clear that the object-linguistic counterfactual simply does not entail its metalinguistic counterpart. In short, McDowell's argument is vitiated by a simple equivocation on 'how things could correctly be said to be.' The second step in his argument is good only if this says something about what words it would be correct to use; the first is good only if it does not.

If what I have said is right, there is after all a gap, discernible by one who rejects objectivity of meaning, between the truth of a statement and its actual verification. Contrary to first

appearances, denying that there are investigation-independent facts (in the sense in which Wright does deny this) does not involve denying that, when we correctly perform an elementary calculation, the correctness of our result is independent of our performance. In that sense we can agree with Dummett that there is, in advance of our carrying it out, a determinately correct result. And more generally, when we make a valid inference from true premises to the conclusion that p, the truth of our conclusion does not wait upon our coming to it; it can, *without presupposing the contractual model*, be acknowledged that it would still have been the case that p, even if we had not drawn the inference. In that sense, by making the inference we acquire knowledge of a fact of which we had previously been ignorant but which was already there to be known. There is, to be sure, more to be said before we can lay claim to a satisfying explanation of the usefulness of deductive inference.[19] But this much is, it seems to me, enough to dispel the appearance that no such account can be forthcoming if the contractual model of meaning is abandoned.

5 Concluding Remarks

I have concentrated here on two discussions, both of which enlist Wittgenstein's rule-following considerations in support of radical and highly revisionary conclusions about the objectivity of meaning – conclusions which may appear to entail, and have been taken to entail, consequences for the objectivity of truth and judgment which are no less radical and revisionary. My principal concern has been to argue that, however unpalatable these conclusions – Kripke's semantic irrealism and Wright's rejection of the contractual model and investigation-independence – may seem, we have as yet no compelling demonstration of their unacceptability, and thus have no advance right to think that the arguments leading to them must be unsound. I should like to conclude with some remarks about how we should view the situation.

First, whilst we have as yet no decisive ground for thinking semantic irrealism unstable, it is quite another question whether any argument Kripke gives, or might have given, compels its acceptance. The greater part of Kripke's argumentation – and certainly the most convincing part of it – is directed against attempts to explain, in naturalistically reductive terms, what it is to mean something by an expression. To the extent that it is effective, it secures its effect by taking undisputed features of the concept of meaning – generality of application and normativity – and showing that they elude explanation on the proposed naturalistic basis. Clearly no argument of this kind could undermine a view according to which semantic or more generally intentional phenomena are irreducible. To establish semantic irrealism requires no less than a demonstration that indispensable features of the concept of meaning cannot be jointly instantiated. The closest Kripke comes to providing one is in his dismissive discussion of the idea that meaning something is a *sui generis* 'unique introspectible state'; but this comes nowhere near to a demonstration that severally essential ingredients in the concept of meaning cannot coexist. Furthermore, the required features are, as Wright reminds us, apparently coherently coexemplified in our standard intuitive notion of intention. We have no *a priori* guarantee that that notion could not turn out to be incoherent; but no reason to think it so is yet in sight.

Matters stand otherwise, it seems to me, with Wright's conclusion. Here we are faced with a *prima facie* compelling argument for the bankruptcy of the contractual model to which, so far as I have been able to see, no effective counter has been provided. And if I am

right, horrified reactions to the ensuing rejection of investigation-independence can be seen to be misplaced, once that notion is properly separated from a more modest notion of objectivity which can perfectly well survive without contractual underpinning. What does then become pressing is the need for a satisfying, detailed account of how we may view meaning as – in Wright's own, somewhat opaque phrase – "shaped by features of our ongoing linguistic behavior." This is one direction in which we have a good way yet to travel, before we can reckon ourselves to have appreciated the full significance of Wittgenstein's remarks on rule-following.[20]

Notes

1 See, in addition to the works cited, Peacocke (1981), McGinn (1984), Budd (1984), Pears (1988, chs 16–18), Williams (1991), Luntley (1991), and Wright (1989, pp. 239–245).
Another important focus of controversy which must be left unexplored here is the exact relationship between Wittgenstein's discussion of rule-following and his arguments against the possibility of a private language. See Chapter 11, MEANING AND PRIVACY.

2 This calls for some qualification: whilst there is, so far as I know, no published attempt to show that perverse Kripkean hypotheses break down when we try to work them through in detail, at least one critic – Neil Tennant – attempts to make such a case in *Taming of the True* (1997).

3 For dispositional theories see, for example, Papineau (1987), Fodor (1987; 1991). For doubts about the efficacy of Kripke's objections, see Blackburn (1984) and Forbes (1983). Attempts to uphold a causal account of meaning or reference in the face of the skeptical argument may be found in Goldfarb (1985) and McGinn (1984, pp. 164–166), who also defends the capacity proposal (pp. 168–175). Chomsky (1986) argues that Kripke improperly restricts the search for meaning-constitutive facts – the claim that you formerly followed a certain rule is a *theoretical* claim, and as such answerable to future evidence, as well as evidence concerning, for example, your past linguistic behavior or conscious mental life. Boghossian (1989) provides a useful survey and assessment of attempts at a straight solution which accept Kripke's reductionist assumption. See Chapter 8, A GUIDE TO NATURALIZING SEMANTICS.

4 For criticism of Kripke's reductionist leanings and proposals for non-reductive solutions, see Boghossian (1989, pp. 540–549), McGinn (1984, pp. 150–164), and Wright (1984a, pp. 772–777).

5 As some commentators, for example, Blackburn (1984, p. 285), have remarked.

6 I cannot, for reasons of space, pursue the matter here – for illuminating discussion, see Wright (1992a) *passim*. See also Chapter 20, REALISM AND ITS OPPOSITIONS, final section.

7 Short version, Boghossian (1989); full dress, Boghossian (1990).

8 The difficulty has been stated with respect to Wright's version of the globalizing argument – but, as Wright himself points out, somewhat similar troubles afflict Boghossian's version: cf. Wright (1992a, pp. 218–220).

9 Blackburn (1989) makes a similar objection to Boghossian's version of the argument. Doubts about the sufficiency of this kind of response to the globalizing argument are developed in Wright (1992a, pp. 222–226).

10 In the later paper (1984b) Wright refers to this doctrine, according to which meanings are conceived of as "fully settled by over-and-done-with behavioral and intellectual episodes," as that of *objectivity of meaning*.

11 Wright conducts this stage of the argument in terms of the question whether sense can be given to the claim that an individual is being faithful to an idiolectic pattern of application. But as I understand it, what really matters, for this part of the argument, is not whether she is viewed as seeking to suit her performance to a pattern peculiar to herself rather than a shared pattern, but whether others are supposed to be able to evaluate her performance.

12 At best, as Wright observes (1980, p. 219), it is far from clear how the probability of communal agreement being in or out of line with the requirements of the ratification-independent pattern could be assessed.

13 Cf. Wright:

> Of course, it may happen that the community changes its mind; and when it does so, it does not revise the judgement that the former view enjoyed consensus. But that is a fact about our procedure; to call attention to it is to call attention to the circumstance that we make use of the notion that we can all be wrong, but it is not to call attention to anything which gives sense to the idea that the wrongness consists in departure from a ratification-independent pattern. (1980, pp. 219–220)

14 McDowell (1984, p. 325). Whether this is a fair assessment of the import of Wright's argument, and whether, in particular, McDowell is right to identify the familiar intuitive notion of objectivity to which he gives expression with that of investigation-independence, are questions to which we must shortly return.

15 The scattered quotations from McDowell are all taken from his (1984, p. 336).

16 In effect, because Dummett is not explicitly discussing Wright's argument, though it may be that he does in fact have that argument in mind.

17 The quotations are from Dummett (1994, pp. 63–64).

18 This is a very rough description. For a much more careful account, see Wright (1984b, pp. 276–283). A needed further refinement of the notion of basic statement is provided in Wright (1992b, pp. 40–42).

19 For further discussion, see Dummett (1973; 1991a, pp. 36–42, 305–306; 1991b, ch. 7).

20 Thanks to Jim Edwards and Crispin Wright for very helpful comments.

Postscript: Factualism and New Problems for Rule-Following

DANIEL WEE

This postscript attempts to outline recent developments in the philosophical literature on rule-following. In recent years commentators have proposed radical interpretations of Kripke's Wittgenstein that take his position to be compatible with a factualist account of meaning ascriptions. Additionally, new problems concerning rule-following have emerged: Crispin Wright argues that there are serious problems for the idea that linguistic competence can be construed in terms of rule-following, and Paul Boghossian contends that certain intuitively plausible accounts of rule-rationalization and explanation are threatened by a vicious regress that leads one to adopt a problematic conception of blind rule-following.

1 Factualist Readings of Kripke's Wittgenstein

One of the more prominent developments in the literature on Wittgenstein's rule-following considerations has been the dispute between factualist and non-factualist readings of Kripke's Wittgenstein (henceforth KW). The traditional reading of Kripke's exposition of Wittgenstein's remarks on rule-following, as exhibited by Hale in the chapter above, construes KW as ultimately advocating a non-factualist account of ascriptions of meaning: the notion that sentences such as "Jones means *addition* by '+'" do not state facts or have truth-conditions. The reason often proffered for this reading is that KW is compelled to accept a skeptical conclusion that there are no facts that constitute an individual's meaning something by an expression, and then – as part of his "skeptical solution" – tries to avoid being committed to an error theory of meaning ascriptions by revoking the notion that meaning ascriptions are fact-stating.

However, this reading of KW has been challenged by an opposing view that takes KW's position to be compatible with the notion that ascriptions of meaning do state facts and possess truth-conditions. This factualist reading of KW has been proposed by a number of philosophers such as (Byrne, 1996; Davies, 1998; Kusch, 2006). Due to space constraints, we shall only be able to sketch a factualist reading proposed by George Wilson (1994; 1998; 2006).

Wilson's reading of Kripke (1982) envisions two interlocutors in a debate on the content and justification of meaning ascriptions. The first is a skeptic who puts forward a skeptical argument and the second is KW, who attempts to defuse the skeptic's radical conclusion via a skeptical solution. But while this rudimentary picture can be gleaned from the traditional readings of Kripke (1982), the matter of how exactly the skeptical solution is a solution to the skeptic's argument is less clear. In particular, commentators have struggled to pinpoint the skeptical claim that KW concedes to his skeptic and the aspect of the skeptical argument that KW tries to counter in his skeptical solution. One of the virtues of Wilson's reading is that, whether or not one accepts his factualist construal of KW, it nevertheless brings into sharp relief what KW and the skeptic do and do not have in common.

We shall start by laying out Wilson's construal of the skeptical argument. Given that Kripke's discussion focuses on functional expressions (e.g., "+" meaning the *addition* function) we will be characterizing the argument in relation to such expressions. However, it is worth remembering that KW's skeptic is advancing a skeptical argument against meaning ascriptions in general, and so analogous arguments can be deployed for other kinds of expressions such as sentences and predicates.

The first premise of the skeptical argument is a condition of meaning imposed by "Classical Realism":

> **Classical Realism (CR)**: If a speaker *S* means something by a functional expression "F," then there is a function *f* that has been adopted by *S* as the standard of correctness for her application of "F."

According to (CR), an individual means something by an expression only if she has associated her use of that expression with some extra-linguistic entity as the standard that governs the correct application of that expression. The extra-linguistic entity concerned differs for the type of expression: for functional expressions it will be a function, for predicates it will be a set of properties, and for sentences it will be a possible fact or state of affairs. As we shall see, this is the crucial premise that Wilson takes KW to be rejecting in his skeptical solution.

The second premise is the "grounding constraint":

> **Grounding Constraint (G)**: If there is a function *f* that has been adopted by *S* as the standard of correctness for her applications of "F," then there must be facts about *S* that fix *f* as the standard that she has adopted for her application of "F."

According to Wilson, the candidates for meaning-facts that KW's skeptic considers and finds fault with are facts that are supposed to satisfy the grounding constraint. The perceived failure to find such facts even under idealized epistemic conditions thus leads the skeptic to draw what Wilson calls the "basic skeptical conclusion":

> **Basic Skeptical Conclusion (BSC)**: There are no facts about *S* that fix any function *f* as the standard of correctness she has adopted for her application of "F."

Thus, the skeptic finally draws his "radical skeptical conclusion":

> **Radical Skeptical Conclusion (RSC)**: No one means anything by a functional expression "F."

According to Wilson, KW's skeptic is committed to the argument from (CR), (G), and (BSC) to the conclusion (RSC). The difference between KW and the skeptic, however, is that KW sees (RSC) as "the incredible and self-defeating conclusion, that all language is meaningless" (Kripke, 1982, p. 71), and so KW endorses the contrapositive argument from ¬ (RSC), (G), and (BSC) to the conclusion ¬ (CR). Given Wilson's structuring of the arguments, it is clear what is shared and disputed between KW and his skeptic: KW and his skeptic both accept (BSC), but KW rejects (RSC) along with the classical realist condition for meaning (CR) that leads to it.

The way is now open for Wilson to argue that KW's skeptical solution can be compatible with factualism about meaning ascriptions. Under the classical realist account, in order for a meaning ascription like "Jones means *addition* by '+'" to be true, there must be facts in virtue of which it is true, and these facts must be facts concerning Jones's relation to the *addition* function as the standard of correctness for her use of "+." But accepting that there are no such facts (as (BSC) claims) is only to accept that there are no meaning-facts under the classical realist construal of what meaning-facts are supposed to be. By rejecting (CR),

KW can still make room for the notion that meaning ascriptions are true in virtue of facts, just that these facts would not be classical realist facts.

Of course, this is only an outline of Wilson's argument for the claim that KW's skeptical solution is compatible with factualism about meaning ascriptions. More needs to be done to show that there are such non-classical realist facts in virtue of which meaning ascriptions can be true. Nevertheless, philosophers have taken Wilson's argument seriously on both its exegetical and its philosophically substantive merits, and the debate between factualist and non-factualist construals of KW is ongoing. For examples of critical replies to Wilson see Miller (2010), Kremer (2000), and Soames (1998).

2 Wright's and Boghossian's Problems from "Blind" Rule-Following

The problem of rule-following expressed in KW's rule-following considerations is that of accounting for someone's internalization or acceptance of a rule. This problem has traditionally been considered the central problem of rule-following, and a wealth of literature has spawned in response to it. However, in recent years Crispin Wright (2007; 2012) and Paul Boghossian (2008; 2012) have independently identified further problems for rule-following that they claim remain even if we have a solution to KW's problem of rule-acceptance. These problems relate to the notion of "blind" rule-following, where we act on certain rules without being able to provide rational justification for why our actions are in accord with them.

2.1 Wright's Challenge to Construing Linguistic Competence as Rule-Following

According to Wright, a further problem emerges for the notion that linguistic competence can be construed in terms of following rules. To see how this problem emerges, Wright contends that in all cases of rule-following, it must be possible to structure the acceptance of the rule and the responses to it in terms of a *modus ponens* model. We can illustrate this model as follows in the case where a chess player makes the judgment that she may now castle:

> **Castling rule**: If neither the King nor one of its Rooks has moved in the course of the game so far, and if the squares between them are unoccupied, and if neither the King nor any of those squares is in check to an opposing piece, then one may castle.
> **Observation**: In this game neither my King nor this Rook have yet been moved, the squares between them are unoccupied, and neither the King nor any of those squares is in check to an opposing piece.
> **Judgment**: I may castle now.

However, Wright thinks that in order to apply the *modus ponens* model to a purported case of rule-following, what constitutes the major and minor premises must be extricable from each other. By "extricable," Wright means that the acceptance of the rule (the major premise) and the observation that the rule's antecedent is satisfied (the minor premise) can figure as independent states of mind. This requirement is imposed by the *modus ponens* model itself,

in order to distinguish between the general rule and the particular circumstances in which it is applied, so that "what properly belongs to the rule corresponds to the conditional major premise […] while what corresponds to the situational input will be given by the minor premise" (Wright, 2007, p. 492).

In the case of the castling rule the extricability condition is easily satisfiable: an individual can describe the positions and interactions of the pieces on the chess board as mentioned in the antecedent of the castling rule without any understanding of the castling rule itself. For instance, there can be chess novices who learn the castling rule only after they have learnt other chess concepts, and so are still able to recognize that neither their King nor Rook has moved, and so on, without having any inkling of the castling rule.

However, Wright thinks that the extricability condition for the *modus ponens* model cannot be satisfied in cases where one attempts to follow rules that govern the use of primitive or basic linguistic expressions, such as those involving "the simple classification of colours, or tastes, or Lockean secondary qualities generally" (Wright, 2007, p. 490). Wright characterizes such cases as instances of "blind" rule-following, "where nothing takes place which can naturally be regarded as *working out* what a rule requires" (p. 490). To illustrate how such a case would fare, Wright considers the example of following the rule for applying "red":

> **Rule for applying "red"**: If … x …, it is correct to predicate "red" of x
> **Observation**: … x …
> **Judgment**: It is correct to apply "red" to x.

In this case, unlike the castling rule, the grasp of the rule for applying "red" is inextricable from the ability to recognize when the antecedent of that rule is satisfied, because the ability to recognize the satisfaction of the antecedent requires mastery of the concept of *red* and hence grasp of the rule for applying "red" itself:

> To conceive of predications of 'red' as rule-governed in the manner of the model accordingly requires an anterior concept, '… x …,' whose satisfaction determines an input as appropriate for the application of the rule. But now it stares us in the face that this concept can hardly be anything other than: *red*! (Wright, 2007, p. 495)

So we arrive at a dilemma: either we maintain that in cases of following rules for using primitive expressions we can extricate the observation of the satisfaction of a rule's antecedent from acceptance of that rule, or we give up the idea that they are extricable and so discard the notion that competent use of primitive linguistic expressions can be construed in terms of rule-following.

If we accept the first horn of the dilemma then Wright believes we are committed to thinking of linguistic competence in terms of the Augustinian picture of language, according to which an individual can possess mastery of a concept anterior to the grasp of the rule of using that concept's expression. Wright finds this horn of the dilemma the worse of the two, and notes that it is something with "which the *Philosophical Investigations* begins and from which, as I put it, that text is a 'journey of recoil'" (Wright, 2012, p. 382). Given this, he is compelled to propose that we cannot construe competence in using primitive expressions in terms of rule-following. And since competence in using primitive expressions forms the basis for competence in using more complex expressions, in the sense that the

latter must be analyzed in terms of the former, it thus appears that we cannot construe linguistic competence in general in terms of following rules.

2.2 Boghossian's Problem for Rule Rationalization and Accepting Rule-Blindness

According to Boghossian, even if we have neutralized KW's problem of rule-acceptance, a further problem looms where we encounter a vicious regress in any attempt to explain or rationalize an individual's action as an instance of rule-following. To set up Boghossian's problem as such, we can help ourselves *pro tem* to the idea that KW's problem has been solved and so we are entitled to hold a non-reductionist view of rule-acceptance that Boghossian calls the "Intention View." This is the view that accepting a rule consists in forming an intention with general (prescriptive or normative) content, such as the intention to perform a certain action under certain circumstances. Boghossian characterizes the "Intention View" as just a specific form of the more general "Intentional View" according to which rule-acceptance consists in some intentional state or other – not necessarily an intention (Boghossian, 2008, p. 485).

Now Boghossian shares with Wright the conviction that all genuine cases of rule-following can be modeled according to a structure much like *modus ponens*. Given this and the Intention View, we can illustrate the case of someone following the rule 'Answer any email (that calls for an answer) immediately on receipt!':

Intention: For all x, if x is an email and you have just received x, answer it immediately!
Premise: This is an email that I have just received.
Conclusion: Answer it immediately!

What seems obvious here is that rule-following always involves inference: to follow a rule is to infer from one's acceptance of a rule and belief that the antecedent conditions of the rule are met, to the conclusion that the judgment that the action called for by the rule is now permissible or required. However, a vicious regress starts to stir when we realize that in performing an inference we are also following a rule of inference – one that can be characterized as:

(MP*) From 'If C, do A' and C, conclude 'do A'!

Consequently, it appears that in attempting to follow the rule for answering emails we need to make an inference, but making that inference itself requires following an additional rule of inference, MP*, and following that rule itself requires making an inference, and so on *ad infinitum*.

The upshot of Boghossian's considerations is that, even if we help ourselves to the Intention View of rule-acceptance, we still face a problem in attempting to rationalize or explain any individual's actions in light of a rule. This is because there seems to be an infinite number of cognitive steps between her acceptance of that rule and her inferring that the action called for by the rule is permissible or required on a particular occasion. It thus seems that in order to avoid such infinite regress, we must reject the Intention View, along with the more general Intentional View, and so concede that the acceptance of at least some

rules "cannot consist in the formation of a propositional attitude in which the requirements of the rule are explicitly encoded" (Boghossian, 2008, p. 495).

The rejection of the Intentional View is already problematic given that it seemed to constitute a promising response to KW's rule-acceptance problem. However, its rejection leads to a further problem of accounting for how someone can be said to follow a rule despite having no propositional attitude stipulating what the requirements of the rule are, and thus being unable to provide any rational justification for why her actions are in accord with the rule. This is a picture of rule-following as "blind" according to Boghossian, and it contrasts with a view where "rule-following is always fully *sighted*, always fully informed by some recognition of the requirements of the rule being followed" (Boghossian, 2008, p. 495). The challenge is thus to explain how rule-following can be "blind" in this highly problematic sense. For further discussion of Wright's and Boghossian's problems see Miller (2015).

The Normativity of Meaning

ANANDI HATTIANGADI

1 Introduction

This chapter investigates the view that meaning is normative. *Meaning* is understood here in a broad sense to include such semantic properties as sense, reference, truth-conditions, content, and the like. *Normativity* can either be viewed as a property of representations or as a feature of the world. Normative representations include the judgment that you ought to give what you can to charity, the concept OUGHT[1] as it figures in that judgment, the statement 'all and only pleasure is good,' and the expression 'good' as it is used in that sentence. Sometimes, it is also held that there are normative facts and properties that correspond to normative representations, such as the fact that you ought to give what you can to charity or the property of goodness. The claim that meaning is normative can involve appeal either to normative representations or to normative facts. Indeed, it is possible to distinguish four versions of the claim that meaning is normative, two of each kind.

(1) *Meaning essentially involves normative judgment*: meaning something by an expression essentially involves following a rule, or making a normative judgment of some kind. (Cf. Brandom, 1994; Kripke, 1982; Ginsborg, 2011; 2012; Glock, 1996; Ichikawa and Jarvis, 2013; McDowell, 1984; Verheggen, 2011.)

(2) *Meaning is a source of normativity*: semantic truths imply or at least metaphysically necessitate normative truths.[2,3] (Boghossian, 1989; Ginsborg, 2011; Glock, 1996; Verheggen, 2011.)

(3) *Meaning facts are determined by normative facts*: the semantic facts supervene on the normative facts (perhaps together with the non-semantic, natural facts). (Cf. Brandom, 1994; Engel, 2000.)

(4) *Semantic concepts are normative*: the *concept* MEANING is normative, as are ascriptions of meaning. (Cf. Brandom, 1994; Gibbard, 2012.)

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

Contemporary discussion of the normativity of meaning can be traced to Kripke's influential discussion of Wittgenstein's rule-following considerations (Kripke, 1982). Recall that Kripke asks what makes it the case that he means ADDITION rather than QUADDITION by 'plus,' where x quus $y = x$ plus y if x, $y \leq 57$, and x quus $y = 5$, otherwise. He argues for the surprising thesis that there is no fact of the matter what anybody means by any word. The idea that meaning is normative appears to play a crucial role in Kripke's argument (Boghossian, 1989; Hattiangadi, 2007; Soames 1997). For instance, Kripke rejects the view that meaning is determined by speaker dispositions on the grounds that "the relation of meaning and intention to future action is *normative*, not *descriptive*" (Kripke, 1982, p. 37). The problem, Kripke says, is "that my present mental state does not appear to determine what I *ought* to do in the future" (Kripke, 1982, p. 56). Since then, a number of philosophers have defended the view that meaning is normative in some sense or other (e.g., Boghossian, 1989; 2005; Bilgrami, 1992; Brandom, 1994; 2000; Gampel, 1997; Gibbard, 1994; 2012; Ginsborg, 2011; 2012; Glock, 1996; Ichikawa and Jarvis, 2013; Kusch, 2006; Lance and O'Leary-Hawthorne, 1998; Millar, 2002; Verheggen, 2011; Whiting, 2007; Zalabardo, 2012).

As Kripke's discussion makes abundantly clear, interest in the normativity of meaning is fuelled in large part by interest in foundational meta-semantics, what might be called the 'hard problem of intentionality.'[4] Are semantic properties identical to natural properties? Do the semantic facts supervene on the non-semantic facts? Can the semantic truths be reductively explained in non-semantic terms?[5] Kripke clearly suggests that the normativity of meaning has a crucial bearing on these questions. Indeed, he suggests that if meaning is normative, then meaning cannot be reductively explained, and concludes that there are no semantic facts. Though few contemporary philosophers adopt Kripke's skeptical conclusion (an exception might be Gibbard, 2012), many have similarly suggested that the normativity of meaning has a bearing on the hard problem of intentionality. The thought is that if meaning is normative, then there is a useful analogy to be drawn between the hard problem of intentionality and the hard problem of normativity – the problem of finding a place in the natural world for normative properties, such as rightness and goodness.

All four versions of the view that meaning is normative mentioned above have been presented as responses to the hard problem of intentionality. In the following, I will ask both whether meaning is normative in any of the four senses given above and if so, what bearing this has on the hard problem of intentionality. As we shall see, the idea that meaning is normative has very little bearing on the hard problem.

Before we proceed, it will be useful to highlight an important distinction that will be relevant to the discussion throughout. This is the distinction between norm-relativity and normativity proper. Norm-relative judgments concern whether or not something satisfies a norm or a standard.[6] Just about anything can figure as a norm or a standard: the school rules, the law, the requirements of rationality, the code of thieves, or a letter to Santa. To judge that wearing a uniform satisfies the school rules, or that squealing is forbidden by the code of thieves, is not to make a normative judgment at all. One way to distinguish normative and norm-relative judgments is in their rational relations to action. It is plausible that you are rationally required to intend to do what you judge that you ought to do in the genuinely normative sense. Yet you are not rationally required to intend to do what you judge to satisfy a norm or a standard in the merely norm-relational sense. A rational agent can judge that squealing is forbidden by the code of thieves, and yet fully intend to squeal.

Norm-relative truths can similarly be distinguished from genuinely normative truths.[7] On the face of it, the fact that wearing a uniform satisfies the school rules is not a normative

fact in any interesting sense; nor is the fact that squealing is forbidden by the code of thieves. On the face of it, the sentences we have used to state these truths merely describe the school rules and the code of thieves. These descriptions do not entail normative truths. Even if squealing is forbidden by the code of thieves, it does not follow that Bill the thief ought to avoid informing the police about his accomplices, or even that he has a *pro tanto* reason to do so. Of course, the fact that Bill will be punished if his accomplices learn that he has squealed may give him a *pro tanto* reason to avoid squealing. Nevertheless, the mere fact that squealing is forbidden by the code of thieves does not itself give him a *pro tanto* reason not to squeal.

The distinction between norm-relativity and normativity proper is crucial to the present discussion because it is only genuine normativity that generates the peculiar puzzles of metaethics. It is only if meaning is genuinely normative that there might be a fruitful analogy to be drawn between the hard problem of intentionality and the hard problem of normativity.

2 Meaning and Normative Judgment

Why think that meaning essentially involves normative judgment? One reason has to do with the familiar thought that language is a conventional activity, much like other conventional activities such as games (Wittgenstein, 1953): just as there are rules of chess, so too are there rules of language. Kripke picks up on this thought when he says that "[o]rdinarily, I suppose that, in computing '68 + 57' as I do, I do not simply make an unjustified leap in the dark. I follow directions I previously gave myself that uniquely determine that in this new instance I should say '125'" (1982, p. 10), and that such directions "must somehow be 'contained' in any candidate for the fact as to what I meant" (1982, p. 11).

The hypothesis that speaking a language essentially involves rule-following is a special instance of the more general thesis that meaning something by an expression essentially involves making a normative judgment of some kind. This is because, as is widely agreed, following a rule involves more than merely acting in accordance with it; it involves in some sense being guided by the rule, or at least accepting or endorsing the rule (Glüer and Wikforss, 2010). This in turn involves making a normative judgment of some kind.

Another motivation for thinking that meaning involves normative judgment derives from the thought that meaning is use. One version of the use theory of meaning, conceptual role semantics, claims that meaning something by an expression essentially involves the disposition to make certain inferences. For example, what it is to mean addition by 'plus' on this view is to be disposed to answer with the sum of any two numbers when asked (e.g., Block, 1986; Field, 1977; Harman, 1999; Peacocke, 1992). However, as Kripke has argued, the fact that you have this disposition is compatible with your meaning something deviant such as quaddition by 'plus.' In the face of this worry, normativists suggest that what it is to mean something by an expression is to be disposed to accept that certain inferential transitions are correct or appropriate. For instance, to mean addition by 'plus' on this view is to be disposed to judge that '125' is the correct answer to 'what is 57 plus 68?' (cf. Glock, 2005; Brandom, 1994).

Does meaning essentially involve normative judgment? There are some excellent reasons to think not. First of all, rules that might be thought to be constitutive of meaning are not the sorts of rules that can be followed (Glüer and Pagin, 1999; Glüer, 1999). Constitutive rules of meaning specify what a sentence means, and this does not naturally coincide with

telling speakers what to do. Consider, for instance, a rule that says: 'plus' means addition in English. This is a *descriptive* rule, which captures a generalization about usage. Since it does not tell anyone what to do, it is not at all obvious what is involved in following it. Indeed, even if you accept such a rule, your acceptance of it can only play the role of a belief in practical reasoning (Glüer and Pagin, 1999; Glüer and Wikforss, 2010). Furthermore, the judgment that some use of an expression accords with its meaning, or that it satisfies a constitutive rule of use is a norm-relative judgment, rather than a normative one.

Some have sought to sidestep this problem by formulating constitutive rules in terms of correctness conditions, and then arguing that correctness is a normative notion (Boghossian, 1989; 2003; Gibbard, 2003). The idea is that in order to mean addition by 'plus' it is necessary to accept or endorse a rule such as the following:

> *Plus-Rule*: $\ulcorner \varphi + \psi = \omega \urcorner$ is correct iff the number denoted by ω is the sum of the numbers denoted by φ and ψ.

If 'correct' is a normative term, having to do with what one ought to do or may do, then to accept *Plus-Rule* is to make a normative judgment of some kind (Boghossian, 2003; Gibbard, 2003). However, 'correct' is not a normative term across all contexts (Bykvist and Hattiangadi, 2013), and it is not a paradigmatic normative term like unqualified uses of 'ought,' 'may,' or 'reason.' So, to make sense of the idea that judgments of correctness have to do with what one ought to do or may do, we need a more precise characterization of what judgments about what one ought or may do are entailed by judgments of correctness.

What normative judgments are entailed by correctness judgments, then? Perhaps a normativist will say that in order to mean addition by 'plus' you must judge that you *ought* to respond with the sum of any two numbers when asked. But this view is implausible. Suppose that you discover that if you do not answer '5' when asked to add 57 and 68 in some circumstance, an evil demon will ensure that thousands will die. Though you will sensibly judge in this situation that you ought not to respond with the sum, we can hardly conclude that you do not mean addition by 'plus.' Or perhaps the normativist will say that to follow *Plus-Rule* you must judge that you *may* respond with the sum of any two numbers when asked (e.g., Whiting, 2009). But this view is equally implausible. For, in the circumstance just described, you sensibly judge that you ought not to respond with the sum, which is incompatible with the judgment that you may do so. The normativist could say instead that meaning addition by 'plus' requires that you judge yourself to have a *pro tanto* reason to respond with the sum of any two numbers when asked, where a *pro tanto* reason is a reason that can be outweighed by other considerations. However, this too is implausible. You might well think that you do not even have a *pro tanto* reason to respond with the sum in the case of the evil demon, yet we cannot conclude from this that you do not mean addition by 'plus' (cf. Glüer, 1999; 2001; Hattiangadi, 2006; 2007; Wikforss, 2001). Perhaps the normativist should say that correctness is a *sui generis* normative notion, not reducible to obligation and permission (cf. McHugh, 2014). He might then say that you must at least judge that responding with the sum is correct in view of what 'plus' means, even if you do not take yourself to have a *pro tanto* reason to do so. But it is difficult to see in what sense correctness is a normative notion if it is possible to coherently judge that some act is correct while simultaneously judging that you lack even a *pro tanto* normative reason to perform that act.

It might be tempting to respond to these cases by insisting that meaning addition by 'plus' essentially involves judgments of *semantic* correctness.[8] That is, in order to mean

addition by 'plus' you must be disposed to judge that it is *semantically* correct to respond with the sum of any two numbers, when asked. The trouble is that to judge that some answer is *semantically* correct is to judge that the answer is correct in view of what it means, or in view of satisfying *Plus-Rule*. And this is a *norm-relative* judgment, not a genuinely *normative* one. You are not rationally required to give the answer '125' merely because you judge that this answer satisfies *Plus-Rule* any more than you are rationally required not to squeal merely because you judge that squealing violates the code of thieves.

Perhaps the normativist will be tempted to recoup, and say that it is sufficient for meaning addition by 'plus' that you judge that you ought to respond with the sum when asked in most cases, even if sometimes, such as in the evil demon case, you do not. But this undermines the thought that these normative judgments are constitutive of what you mean. Let's say that *schmaddition* denotes a function that deviates from the addition function only in those cases in which you are morally required not to respond with the sum. In particular, let's say that in the evil demon case, the schmaddition function delivers the answer '5.' Clearly, the pattern of normative judgments you are typically disposed to make is consistent with your meaning schmaddition rather than addition by 'plus.' Indeed, more of the normative judgments you are disposed to make are consistent with your meaning schmaddition by 'plus' than are consistent with your meaning addition by 'plus.' Assuming that you do not mean schmaddition by 'plus,' what you mean cannot be determined by which normative judgments you are typically disposed to make.

Hannah Ginsborg (2011) puts a kind of particularist twist on the idea that meaning involves normative judgment. According to her, meaning something by an expression need not involve explicit acceptance or endorsement of any rule, only a kind of implicit rule-following. What it is to implicitly follow a rule for Ginsborg is to be disposed to make the appropriate pattern of normative judgments. For instance, on her view, it is necessary for meaning addition by 'plus' that a subject be disposed to judge that '57 + 68 = 125' is correct, that '125' is the answer one ought to give to '68 + 57 = ?' She describes this as a 'primitive' attitude in the sense that it need not be the result of conscious rule-following, or even the product of a *post hoc* realization of which rule one has been following (Ginsborg, 2011). Yet this particularist twist does not help to address the foregoing objections. Since judgments of correctness are not normative in every context, we need to know what normative judgments correspond to these primitive judgments of correctness. Perhaps Ginsborg will say that to mean addition by 'plus' one must be disposed to judge that one ought to or has a reason to answer with the sum, whenever one is asked to add any two numbers. But in the evil demon case, you are not disposed to judge that you ought to or even have a reason to answer with the sum, yet it does not follow that you do not mean addition by 'plus.' If Ginsborg attempts to relax the condition, and say that meaning addition by 'plus' involves making the relevant pattern of normative judgments most of the time, the pattern of normative judgments you typically make will not determine what you mean, since your dispositions will be compatible with the hypothesis that you mean schmaddition, or some other such bizarre function by 'plus.'

Claudine Verheggen (2011) claims instead that understanding the meaning of an expression or a sentence essentially involves the acceptance of certain instrumental oughts. On her view, it is essential to meaning addition by 'plus' that you accept that *if* you want to tell the truth, then you ought to say that 57 + 68 = 125 when asked. This suggestion avoids the above difficulties, because one can coherently accept this instrumental ought statement in the evil demon case, while accepting that all things considered, one ought not to give the

answer 125. The trouble is that instrumental ought judgments are merely norm-relative, not normative. 'If you want to get rich, you ought to be ruthless,' is norm-relative since it says that being ruthless is a necessary condition for satisfying the desire to be rich (against the background of the common knowledge of the context). Instrumental ought statements are not genuinely normative because they *describe* a necessary condition for satisfying a desire in context, and generally speaking, we do not think that statements describing necessary conditions are genuinely normative.[9] Thus, even if Verheggen is right that meaning essentially involves instrumental ought judgments, it does not follow that meaning essentially involves normative judgments.[10]

So far, we have considered internalist versions of the view that meaning involves normative judgments. Externalists deny that a speaker's private normative judgments are essential to what she means. Those externalists who hold that normative judgment is essential to meaning appeal instead to the normative judgments of the wider community, or communal practices in which those judgments are implicit. Such an externalist will be impatient to respond to the foregoing objections by appeal to a rule-governed practice, or some other such social mechanisms. For instance, Brandom argues that meaning something by an expression is constituted by inferential rules which are maintained by a practice of 'deontic scorekeeping' in which participants of the practice keep track of which inferences you are committed to or are entitled to make. For instance, in our practice, from a statement of 'x is red' you are committed to saying that 'x is colored' if asked; similarly, you will be permitted by our practice to say '57 + 68 = 125' and not permitted to say '57 + 68 = 5.' Now, you might on some occasion make a mistake, and forget to carry, but what you mean by 'plus' is not affected by this, since it is determined by the community-wide pattern of normative judgments. When you make such a mistake, it follows that you have said something that is not permitted by the semantic practices of your community. However, this sort of view fares no better with respect to the difficulties we have just canvassed than the views rejected previously. Just as you will sensibly judge in evil demon cases that you have no reason to respond with the sum, so too will many of your peers. Even if the whole community judges that you have no reason to answer with the sum in the evil demon case, it does not follow that you do not mean addition by 'plus' (cf. Hattiangadi, 2003).

It is time to move on to the question whether the hypothesis that meaning involves normative judgment has any bearing on the hard problem of intentionality. Recall that Kripke argues that dispositionalism fails because meaning is normative. He suggests the following argument: if meaning is normative, and normativity cannot be reductively explained, then meaning cannot be reductively explained either (cf. Boghossian, 1989; Gibbard, 2012; Kripke, 1982; Verheggen, 2011). But this is a *non sequitur*. The claim that meaning essentially involves normative *judgments* does not entail that there are any normative *facts*, yet the claim that normativity cannot be reductively explained concerns normative *properties* or *facts*. If meaning is constituted by normative *judgments*, and normative *facts* or *properties* cannot be reduced, it does not follow that meaning cannot be reduced. All that follows from the claim that meaning essentially involves normative judgment is that any reductive explanation of meaning must reductively explain normative judgment. But there is no *prima facie* reason to think that normative judgments are more difficult to reductively explain than non-normative judgments. Indeed, if there is a difficulty for a naturalist dispositionalist to reductively explain normative judgment, this difficulty seems to arise because normative judgments have *semantic properties*, not because the judgments are normative. That is,

if a dispositionalist account of normative judgment is unsatisfactory, this is because normative judgments have semantic properties, not because meaning is normative.

In contrast to Kripke, others appeal to the normativity of meaning in order to provide a positive, reductive account of meaning (e.g., Ginsborg, 2011; Brandom, 1994). These normativists grant that meaning cannot be reductively explained in natural scientific terms, but suggest that they can give an account of meaning that answers Kripke's problem in natural and normative terms. However, the claim that meaning essentially involves a normative judgment does not aid this reductive explanatory project either. The reason is that normative judgments themselves have semantic properties, so a reductive explanation that appeals to normative judgments in the *explanans* will be viciously circular. Recall that a reductive explanation of meaning is an explanation of meaning in *non-semantic* terms. Since normative judgments have semantic properties, they cannot figure in a reductive explanation of meaning.

Might the hypothesis that meaning involves normative judgment constitute a *partial* naturalistic solution to the hard problem of intentionality (e.g., Ginsborg, 2011)? Perhaps the reductive explanation of meaning proceeds in stages: first, we reductively explain meaning in terms of normative judgments, and then we give a reductive explanation of normative judgments. However, there is no obvious reason to think that the task of giving a reductive explanation of normative judgments is in any way easier than the task of giving a reductive explanation of linguistic meaning in the first place.

3 Meaning as a Source of Normativity

As we have seen, there is good reason to reject the view that meaning essentially involves normative judgment. However, there is a potentially more plausible idea in the vicinity. This is the idea is that (a) meaning is constituted by rules and (b) the rules constitutive of meaning are *sources of normativity*, that is, that they entail genuinely normative truths. This idea also goes back to the intuitive view that speaking a language is a conventional activity, much like playing chess. However, the thought is not that if you mean addition by 'plus,' then you *judge* that you ought to follow *Plus-Rule*. Rather, the thought is that if you mean addition by 'plus,' you *ought* to or have a *normative reason* to do what *Plus-Rule* requires of you.

Let us assume for the sake of argument that meaning is constituted by rules or requirements of some kind. This does not prejudge the question whether meaning is normative. We need only assume that constitutive requirements are 'property-requirements' in John Broome's sense (Broome, 2013). For instance, the rule in chess that states that the bishop ought to be moved only along the diagonal constitutes what it is to be a bishop in chess; it constitutes the property of being a bishop. In assuming this, we do not assume that the rules of chess are normative. By analogy, we can assume that *Plus-Rule* constitutes the property of meaning addition by 'plus' without assuming that *Plus-Rule* is normative. Similarly, there are requirements of the law, of rationality, of the code of thieves, of the school, and so forth. And with respect to any system of property requirements, we can ask the normative question. We can ask whether any such system of requirements is a source of normativity, that is, whether it is necessarily the case that one ought to do or has reason to do what the system of requirements requires of one.

Several proponents of the normativity of meaning have suggested that constitutive rules of meaning are sources of normativity. For instance, Boghossian once claimed that what follows

from the fact that you mean *green* by 'green' is a host of normative truths, such as that you ought to apply 'green' to something if and only if it is green (Boghossian, 1989). And Ginsborg (2012) claims not only that someone who means addition by 'plus' makes a certain pattern of normative judgments, but also that these judgments are those someone who means addition by 'plus' ought to make (see also Whiting, 2009). These philosophers seem to be saying that rules (requirements or principles) that determine meaning determine some normative facts.[11] It is *because* some course of action is required by meaning or content constitutive rules that one ought to, or has a normative reason to, carry out that course of action.

Unlike the view that meaning involves normative judgment, the view that meaning is a source of normativity does seem to have a direct bearing on the hard problem of intentionality. Suppose that semantic truths entail normative truths. If a satisfactory reductive explanation of meaning must explain everything that is entailed by the semantic truths, then any satisfactory reductive explanation of meaning will have to provide a reductive explanation of normativity as well. If normativity cannot be reductively explained, then meaning cannot be reductively explained either. Similarly, suppose that semantic facts metaphysically necessitate some normative facts. Then these normative facts supervene on the semantic facts, and any non-semantic supervenience base must metaphysically necessitate both the semantic and the normative facts. The claim that meaning is a source of normativity would have a bearing on whether meaning can be naturalized, if it were true. But as we shall see, a strong case can be made that it is not true.

Following Broome (2013), we can distinguish between a strong and a weak version of the claim that some norm *R* is a source of normativity:

> *Strong Normativity*: Necessarily, if *R* requires that you φ, then you ought to φ because *R* requires that you φ.
>
> *Weak Normativity*: Necessarily, if *R* requires that you φ, then the fact that *R* requires you to φ gives you a normative reason to φ.

In *Weak Normativity*, the reason *R* engenders could be merely *pro tanto*, that is, a reason that can be outweighed by other considerations. We have assumed, for the sake of argument, that meaning 'plus' is constituted by *Plus-Rule*. Is *Plus-Rule* either strongly or weakly normative?

Recall that *Plus-Rule* requires that you respond with the sum of any two numbers when asked. Of course, in many cases, responding with the sum is what you ought to do, but this is rarely simply because responding with the sum is required by the rule that constitutes what you mean. Sometimes, you ought to respond with the sum because you will benefit – if you are sitting an examination in mathematics, for instance. At other times, you ought to respond with the sum because this is what you morally ought to do. And sometimes you ought to respond with the sum because of a desire to communicate what you believe (cf. Hattiangadi, 2007; Glüer, 1999; 2001; Wikforss, 2001). But it is not necessarily the case that you ought to respond with the sum whenever you are asked, as in the evil demon case we have discussed previously.

Indeed, it is implausible that meaning constitutive rules such as these are even weakly normative. Of course, if you do have a normative reason to answer with the sum, this may accompany other prudential or moral reasons you might have to do so in a given context.

However, it is not plausible that the mere fact that answering with the sum is required by *Plus-Rule* necessarily gives you a genuinely normative reason to respond with the sum. One way to test this is to consider the evil demon case again, using the following heuristic: ask what a responsible agent ought to consider when deciding what to do. A responsible agent, when deciding what to do in a situation, will consider all of the facts that are normatively relevant to what she ought to do in that situation. Any *pro tanto* reason to do A or not to do A that is genuinely normative will be normatively relevant to whether an agent ought to do A. So, we can get a grip on which facts constitute *pro tanto* reasons for or against giving the answer '5' in the evil demon case by considering which facts will be taken into consideration when a responsible agent decides what to do in that case. Clearly, the fact that giving an answer other than '5' will cause the loss of life is normatively relevant, and constitutes a genuinely normative reason to give the answer '5.' An agent who failed to take this into account in deciding what to do would be irresponsible. In contrast, the fact that the agent is required by meaning-constituting rules to answer '125' does not seem to be normatively relevant in this case at all. An agent who failed to take this fact into account in deciding what to do, all things considered, would not be irresponsible. Thus it seems that the fact that *Plus-Rule* requires that you answer '125' does not even give you a *pro tanto* reason to do so in the evil demon case, as if that reason hung in the balance against the loss of life (Thomson, 2008).

Perhaps it will be tempting to respond by distinguishing semantic oughts from moral, prudential, or epistemic ones. In the case where you are faced with a choice between answering with the sum of two numbers and allowing thousands to die, or not answering with the sum and letting them live, there are two spheres of normativity that clash: what you *semantically* ought to do and what you *morally* ought to do. Even if what you ought to do, all things considered, is in this case identical with what you morally ought to do, it does not follow that it is not the case that you semantically ought to respond with the sum.

However, facts concerning what one *semantically* ought to do are merely norm-relative, not genuinely normative. We have assumed, for the sake of argument, that meaning is constituted by rules or requirements of some kind, that if you mean addition by 'plus' then you are semantically required to respond with the sum of any two numbers when asked. If what you semantically ought to do is just what you ought to do in view of the relevant semantic requirements, it is trivial that you semantically ought to do what is semantically required of you. Similarly, it is trivially true that you legally ought to do what the law requires of you, that you rationally ought to do what rationality requires of you, and that you morally ought to do what morality requires of you. Yet it remains an open question whether you ought to do what you morally ought to do, legally ought to do, or rationally ought to do. These are *qualified* oughts, which are norm-relative, not the *unqualified* ought, which is genuinely normative. Indeed, any system of normative requirements can be seen to give rise to qualified oughts. For instance, what you *satanically* ought to do is what you ought to do in view of the requirements of a satanic cult. In each of these cases, there is a *further question* whether one ought to do in the unqualified sense what one ought to do in some unqualified sense. In asking whether one ought to do what the law requires or whether one has reason to do what rationality requires, we use 'ought' in an *unqualified* sense (Broome, 2013).[12] It is this unqualified concept of 'ought' that figures in genuinely normative judgments. Correspondingly, there are unqualified concepts of permission, reason, and goodness.

Thus, even if we grant that you semantically ought to do what is semantically required of you, there is a further question whether these systems of norms are sources of normativity – whether you ought to or have reason to do what these systems of norms require of you in the unqualified sense of 'ought' and 'reason'. To be reminded that what you semantically ought to do is what is semantically required of you does not address this further question.

To sum up: when we ask whether morality, rationality, or semantics is a source of normativity, we are using the unqualified, genuinely normative concepts of 'ought' and 'reason.' As we have seen, it is implausible that meaning-determining rules are even weak sources of normativity. That is, it is implausible that if you mean addition by 'plus,' then the fact that you are semantically required to answer '125' gives you even a *pro tanto* reason to do so in the evil demon case. Though the view that meaning is a source of normativity would have a bearing on the hard problem of intentionality if it were true, it does not seem to be true.

4 The Normative Determination of Meaning

The view that meaning is a source of normativity is the view that semantic truths entail or metaphysically necessitate normative truths. An alternate version of the normativity thesis holds that the determination relation goes in the opposite direction. According to this view, the semantic or intentional facts are determined by normative facts (perhaps together with the natural facts). This view is motivated by the failure of attempts to give a naturalistic explanation of meaning. The normativist's proposal is to add normative truths to the reductive explanation or normative facts to the supervenience base. Even if meaning cannot be explained in *naturalistic* terms, perhaps it can be explained in naturalistic and normative terms.

This proposal has an obvious bearing on the hard problem of intentionality. For instance, one might hold that the semantic truths can be *reductively explained* in terms of the normative and natural truths. Second, one might hold that the semantic facts *supervene on* the natural and normative facts. Of course, one might hold both views.[13] It is important to note that none of these views holds much interest in the present context if meaning can be reductively explained in naturalistic terms alone. For then, any normative statements added to a reductive explanation would be nugatory. So, for the purposes of the present discussion, we can assume that meaning cannot be reductively explained in purely naturalistic terms. Our question is whether anything can be gained by adding normative statements to the reductive explanation or by adding normative facts to the supervenience base.

There are broadly speaking two approaches to the reductive explanation of meaning: holistic and atomistic. The holistic approach, associated most famously with Lewis (1974) and Davidson (1973), starts with the totality of relevant non-semantic information and then assigns beliefs, desires, and meanings in accordance with certain constraints on interpretation, such as most notably, some kind of principle of charity. The atomistic approach, associated with Fodor (1990), Dretske (1997), Millikan (1984), and others, starts by giving a reductive explanation of mental representations and then attempts to build a reductive explanation of beliefs, desires, and the meanings of sentences on this foundation. The contents of mental representations are reductively explained in terms of causal covariation: if a mental representation *X* causally covaries with the presence of *Fs*, then *X* picks out, or represents the *Fs*.

The atomistic approach is broadly dispositional. In its crudest version, it says that you mean addition by 'plus' if and only if you are disposed to answer with the sum of any two numbers when asked. Kripke argues that such a view faces the problem of error. Sometimes, you are disposed to make mistakes, and thereby fail to answer with the sum. What the dispositionalist needs is some way of distinguishing the meaning-constituting dispositions from those that are error-producing (Boghossian, 1989). This suggests a role for normativity in the reductive explanation of meaning. Perhaps it is a normative property of dispositions in virtue of which they are meaning-constituting rather than error-producing.

Which normative property? Perhaps the disposition to answer with the sum is meaning-constituting in virtue of being the disposition to give the answer that you ought to give. That is, you mean addition by 'plus' if and only if you are (a) typically disposed to answer with the sum, and (b) the sum is the answer that you ought to give. The trouble is that in the evil demon case it is false that you ought to answer with the sum. But it does not follow that you do not mean addition by 'plus.'

Alternatively, one might suggest that the disposition to answer with the sum is meaning-constituting iff it is a disposition to give the answer that is semantically correct. That is, you mean addition by 'plus' if and only if you are (a) typically disposed to answer with the sum, and (b) the sum is the answer that is semantically correct.[14] This might avoid the foregoing problem, but it violates a plausible circularity constraint on reductive explanation. The property of being semantically correct is itself a semantic property – it is the property of being correct *in virtue of meaning*. And an appeal to this property in a reductive explanation of meaning violates a circularity constraint on a satisfactory reductive explanation. If any semantic or properties figure in an explanation of intentionality, then that explanation is not fully reductive.

A third option might provide a middle way. Perhaps the meaning-constituting dispositions are the *rational* dispositions (cf. Wedgwood, 2009). A rational disposition is one that is triggered by the normative property of being rational. This might avoid the circularity worry, since what you rationally ought to do is what you ought to do *in virtue of the requirements of rationality*, not in virtue of meaning. However, it does not deal well with the evil demon case. Arguably, if you want most of all to avoid the loss of life, then giving the answer '5' is rationally required in that case. But if your disposition to answer '5' is rational, then according to the view currently under consideration, it follows that you mean schmaddition, rather than addition by 'plus.'

We can present the problem for the normative dispositionalist in the form of a dilemma. Either the dispositionalist makes use of the concept of *semantic* correctness in the reductive explanation of meaning, or she makes use of some other qualified or unqualified normative concepts. If she adopts the first strategy, then she violates a circularity constraint on reductive explanation. If she adopts the second strategy, then she gets the wrong result, such as that you mean schmaddition by 'plus.' Either way, reductive explanation fails.

Now let's return to the holistic approach. Consider Lewis's holistic defense of semantic naturalism. Lewis claims that a radical interpreter, who knows all of the physical truths *P* and grasps our concepts of belief, desire, and meaning, is in a position to deduce *a priori* what an arbitrary subject such as Karl believes, desires, and means. She achieves this feat by applying constraints on interpretation, such as a principle of charity: she represents Karl's beliefs and desires with probability and utility functions that assign the highest expected utility to the acts Karl performs, and assigns beliefs that are rational in light of Karl's evidence. Lewis's proposal is intended to be fully reductive, but he does not suggest that it is in

the slightest bit normative. Davidson, who also claims that radical interpretation is possible, is not after a reductive explanation of intentionality (Davidson, 1990), though he sometimes suggests that his account is normative (Davidson, 1990).[15] So, let us consider the hypothesis that radical interpretation is not possible if the radical interpreter's knowledge is restricted to the non-normative, naturalistic information, but that radical interpretation *is* possible if the radical interpreter is allowed to appeal to normative information of some kind. Can a judicious dose of normativity allow the interpretationist to avoid well-known difficulties that are otherwise unresolved?

One such unresolved difficulty is the 'permutation problem' faced by interpretationist accounts of the foundations of meaning (Davidson, 1973; Field, 1973; Putnam, 1980; Quine, 1964; Williams, 2007). Consider a radical interpreter who adopts a 'global descriptivist' strategy: her data consists of the set of sentences Karl holds true, or perhaps, would hold true under ideal conditions. This constitutes Karl's global theory, ***T***. She then assigns truth-conditions to sentences of Karl's language in such a way as to maximize truth in ***T***. The assignment of extensions to lexical items simply falls out of the assignments of meanings to sentences. The permutation problem for the global descriptivist goes as follows: from any interpretation, *x*, it is possible to construct a competing interpretation *y* that is equivalent to *x* in the assignment of truth-values to sentences of ***T***, but which assigns bizarre extensions to lexical items. To fix ideas, suppose that Karl holds true the sentence *s* 'all emeralds are green.' Now, let *x* be an interpretation that assigns the set of emeralds to 'emeralds' and the set of green things to 'green,' thereby rendering *s* true. We can easily construct an interpretation *y* that assigns the set of emerires to 'emeralds,' and the set of grue things to 'green,' where something is grue iff it is observed before *t* and found to be green, or is blue otherwise, and where something is an emerire iff it is observed before *t* and found to be an emerald, or is a sapphire otherwise. Though *y* is a bizarre interpretation, it too renders *s* true.[16]

Can this problem be resolved if the radical interpreter is allowed recourse to some normative information? It is sometimes suggested that radical interpretation will succeed if the radical interpreter is allowed information about what is *rational*. That is, if the radical interpreter knows which beliefs are rational in light of Karl's evidence, or which belief/desire pairs would rationalize Karl's behavior, then she will be able to apply the principle of charity and thereby rule out deviant interpretations. One might argue that Karl's evidence confirms the belief that all emeralds are green, while it does not confirm the hypothesis that all emerires are grue (Goodman, 1983; Lewis, 1984). As Goodman would put it, neither 'emerire' nor 'grue' are instance confirmable, projectible predicates. However, as Davidson argued, only sets of predicates can jointly be deemed projectible and instance confirmable. Just as an observation of a green emerald confirms the hypothesis that all emeralds are green, an observation of a grue emerire confirms the hypothesis that all emerires are grue (Davidson, 1980, p. 226). Which beliefs are rationalized by Karl's evidence will depend in part on how Karl conceptualizes the evidence, which perceptual beliefs his perceptual experiences generate. If he acquires the perceptual belief that there is a grue emerire before him, then it is rational for him to increase his confidence in the hypothesis that all emerires are grue. So, even if the radical interpreter knows which beliefs would be rational in the face of the evidence, since she doesn't know how the evidence is conceived, this information will not help her to rule out the permuted interpretation.

Another thought might be to allow the radical interpreter information about which of Karl's utterances are semantically correct, or which ones Karl semantically ought to make. Once again, this suggestion violates the circularity requirement on reductive explanation. If

'semantically correct' means 'required by the semantic requirements' and the semantic requirements are constitutive rules like *Plus-Rule*, statements concerning semantic correctness are equivalent to semantic statements. Thus, the holist faces a dilemma very similar to that of the atomist. If the holist appeals to facts about semantic correctness, she violates a circularity requirement, whereas if she appeals to facts of some other kind, such as facts about what is rational, she fails to provide a reductive explanation.

Thus it is not obvious that there is anything to be gained by adding normative truths to the reductive explanation of meaning. At any rate, doing so does not seem to resolve well-known difficulties that beset such reductive explanation. As a consequence, we have no positive reason to think that the semantic facts are determined by normative facts.

5 The Normativity of Semantic Concepts

In his recent book, Allan Gibbard (2012) argues not that meaning is normative, but that the concept MEANING is normative, much like paradigmatic normative concepts such as GOOD and OUGHT. He claims further that meta-representational ascriptions of meaning, such as "Shah means addition by 'plus'" are normative, not descriptive, as are self-ascriptions of meaning, and ascriptions of propositional attitudes. Gibbard combines this view with his own brand of expressivism about normativity according to which assertions of normative statements do not purport to describe how things are, but express something akin to plans. Similarly, he maintains that assertions of metalinguistic ascriptions of meaning, such as 'Shah means addition by "plus"' do not describe, but express plans. Gibbard's claims here appear to be consonant with Kripke's 'skeptical solution' to the skeptical problem.[17] Yet, his approach is further developed. He aims to shed light on Kripke's problem by exploiting an analogy with metaethics. In metaethics, the expressivist says that because moral sentences are non-descriptive, there is no need to postulate any moral facts out there in the world to correspond to them. By the same token, Gibbard suggests that if semantic ascriptions are non-descriptive, there is no need to postulate any semantic facts out there in the world to correspond to them. He hopes thereby to dissolve Kripke's problem.

Gibbard introduces his claim that the concept MEANING is normative with the slogan "'means' entails 'ought.'" "Ascriptions of meaning," he says, "imply straight ought ascriptions" (Gibbard, 2012, p. 11). He adds that these entailments "could only be analytic or conceptual" (Gibbard, 2012, p. 23). That is, ascriptions of meaning, such as "Pierre means DOG by 'chien,'" entail ascriptions of oughts, such as "Pierre ought to…" and these entailments hold in virtue of the meaning of 'meaning' or equivalently, in virtue of the concept MEANING. Anyone who grasps the concept MEANING must accept the normative entailments of meaning ascriptions.

What are the normative entailments of meaning ascriptions? Here are two examples drawn from Gibbard's discussion, where the first statement of each pair is said to conceptually or analytically entail the second:[18]

(1a) The sentence 'Schnee ist weiss' in Ursula's language means SNOW IS WHITE.
(1b) Ursula ought to accept 'Schnee ist weiss' iff snow is white.

(2a) Pierre's sentence 'les chiens aboient' means DOGS BARK.
(2b) If Pierre has sufficient undefeated evidence that dogs bark in an epistemic circumstance *E*, then Pierre ought to accept the sentence 'les chiens aboient' in *E*.

If these entailments are analytic, as Gibbard suggests, then anyone who grasps the concept MEANING must accept that (1a) entails (1b), and that (2a) entails (2b), on pain of irrationality or conceptual confusion.[19] However, it is possible for someone to sensibly deny these entailments without thereby displaying either irrationality or confusion about the concept MEANING.

First, consider an evidentialist, such as William Clifford, who holds that one ought never to believe anything on insufficient evidence (Clifford, 1877). Suppose that we present Clifford with a hypothetical scenario in which Ursula is a speaker of German; the sentence 'Schnee ist weiss' means that snow is white in Ursula's language; snow is in fact white; but Ursula has never seen snow, and lacks any testimonial evidence as to its color. Since Ursula lacks sufficient evidence that snow is white, Clifford would judge that Ursula ought not to believe SNOW IS WHITE. Moreover, note that according to Gibbard, one way to believe SNOW IS WHITE is to accept a sentence in a language one understands that means that snow is white (cf. Gibbard, 2012, pp. 27, 44). It follows from this that Clifford's judgment that Ursula ought not to believe SNOW IS WHITE is tantamount to the judgment that Ursula ought not to accept the sentence 'Schnee ist weiss.' Thus, Clifford would accept (1a) but not (1b). Yet, in so doing, he would display neither irrationality nor confusion about the concept MEANING. Even if we think Clifford is mistaken, his mistake is not conceptual, because his reasons for rejecting the entailment from (1a) to (1b) have to do with his acceptance of evidentialism, and nothing to do with his grasp of the concept MEANING. Thus, (1a) does not analytically entail (1b) (cf. Whiting, 2015).

It can be shown in a similar fashion that the entailment from (2a) to (2b) is not analytic. Consider Blaise Pascal (1670), who holds that there can be pragmatic reasons for belief. Suppose that we present Pascal with a hypothetical situation in which Pierre is a monolingual speaker of French who has sufficient undefeated evidence that dogs bark, but is promised eternal bliss if he does not accept the sentence 'les chiens aboient' and eternal torture if he does. With regard to this situation, Pascal would accept (2a), but deny that Pierre ought to believe DOGS BARK. Since Gibbard assumes that believing DOGS BARK is tantamount to accepting a sentence in one's language that means DOGS BARK, it follows that Pascal would reject (2b). Yet in so doing, he need display neither irrationality nor confusion about the concept MEANING. Even if Pascal's view that there can be pragmatic reasons for belief is mistaken, his mistake is not conceptual. His grounds for rejecting the inference from (2a) to (2b) have to do with his pragmatism, not with his grasp of the concept MEANING.[20] Thus, (2a) does not analytically entail (2b).

One way to respond to these objections might be to appeal to the notion that there are distinct spheres of normativity: such as *inter alia*, epistemic, prudential, and semantic normativity. One might then say that what (1a) and (2a) entail are (1c) and (2c), respectively:

(1c) Ursula *semantically* ought to accept 'schnee ist weiss' iff snow is white.
(2c) If Pierre has sufficient undefeated evidence that dogs bark in an epistemic circumstance *E*, then Pierre *semantically* ought to accept the sentence 'les chiens aboient' in *E*.

One could argue that even if Clifford could sensibly reject the inference from (1a) to (1b), he would have to be conceptually confused to reject the inference from (1a) to (1c). What Clifford ought to say about Ursula's case is that she *epistemically* ought not to believe that snow is white, but that she *semantically* ought to accept the sentence 'schnee ist weiss' nonetheless. Similarly, one could argue that even if Pascal could sensibly reject the inference from (2a) to (2b), he would have to be conceptually confused to reject the inference from

(2a) to (2c). What Pascal should say is that while Pierre *prudentially* ought not to believe DOGS BARK, he *semantically* ought to accept the sentence 'les chiens aboient' nonetheless.

However, this response is not available to Gibbard, who claims that semantic ascriptions entail 'Ewing's primitive oughts.' In Ewing's sense of 'ought' to say 'you ought to do *X*' is to say that you ought to do *X*, all things considered, or that you have a conclusive reason to do *X* (Gibbard, 2012, p. 14). Ewing's sense of 'ought' is just the unqualified sense of 'ought' that we have already come across. Thus, Gibbard's official view is that (1a) entails (1b), and (2a) entails (2b), where both (1b) and (2b) are understood as all things considered oughts, not that (1a) entails (1c) nor that (2a) entails (2c).

Moreover, it *is* possible for someone to sensibly reject the inference from (1a) to (1c), or from (2a) to (2c), without displaying any conceptual confusion, so even these entailments are not plausibly analytic. To see why, it will help to generalize (1c) and (2c). Let *S* be a subject; assume that sentence 's' means *P* in the language spoken by *S*, and that 's' is true iff *p*. We can generalize (1c) and (2c) as follows:

(1d) *S semantically* ought to accept 's' iff *p*.
(2d) If *S* has sufficient undefeated evidence that *p* is true in an epistemic circumstance *E*, then *S semantically* ought to accept 's' in *E*.

First, note that (1d) and (2d) can come into conflict.[21] Assume that Anna speaks Swedish, in which 'häxor existerar' means WITCHES EXIST; it is not the case that witches exist, yet Anna has sufficient undefeated evidence that they do. In this case, (1d) will entail that it is not the case that Anna ought to accept 'häxor existerar' whereas (2d) will entail that *S* ought to accept it. A proponent of a truth-conditional meaning theory, who holds that truth is all that semantically matters for sentence acceptance (belief), would accept (1d) but not (2d), whereas a verificationist, who holds that evidence is all that matters semantically for sentence acceptance (belief), would accept (2d) but not (1d). Yet neither of them need be confused about the concept MEANING. Their dispute concerns the nature of the semantic norms. It is possible for someone to endorse either position without thereby displaying confusion about the concept MEANING.

Perhaps Gibbard would argue that the dispute between the advocate of (1d) and the advocate of (2d) is a substantive normative dispute. He might suggest that the concept MEANING is normative in the sense that to grasp the concept MEANING one must accept that meaning ascriptions have *some* normative implications – one ought to accept *either* (1d), (2d), or similar – though it does not matter *which* normative implications one takes semantic ascriptions to have. This would suggest that Gibbard's view is that the concept MEANING is a 'thin' normative concept like GOOD or OUGHT which lacks any significant descriptive content, rather than a 'thick' normative concept like JUSTICE or COURAGE, which has a significant descriptive content (cf. Gibbard, 2012, p. 39).

Why should we think that MEANING is a thin normative concept? Many semantic anti-normativists will be inclined to deny that meaning ascriptions have any normative entailments. If this denial is sensible, then MEANING is not a thin normative concept. However, since I count myself among the semantic anti-normativists, I am inclined to think that our reasons for denying meaning ascriptions have any normative entailments are sensible.[22] But, what positive reasons does Gibbard give for accepting the normativity thesis?[23] The chief reason is that the normativity of the concept MEANING explains why certain basic oughts follow from semantic ascriptions 'invariably' (Gibbard, 2012, p. 16). However, this

rings hollow in light of the foregoing discussion. As we have seen in the cases above, there are sensible grounds to question whether semantic ascriptions really do entail basic oughts invariably.

Another reason Gibbard provides is that viewing the concept MEANING as normative promises a satisfactory expressivist resolution to Kripke's problem. Whether this is a good reason to accept that MEANING is a thin normative concept depends on whether expressivism does offer a satisfactory resolution to Kripke's problem.

So, does it? To assess this, it will help to have a picture of how the expressivist solution goes in the moral domain. In this domain, the expressivist says that moral statements do not describe but prescribe, and that moral judgments are not straightforwardly factual beliefs. Rather, moral statements express non-cognitive attitudes of some kind – in Gibbard's view, they express a special kind of contingency plan. If moral statements express plans, then there is no need to postulate any moral properties or moral facts out there in the world to correspond to them. In this way, the expressivist proposes to dissolve the hard problem of morality. If there is no need to postulate a property of goodness, there is no need to explain, in non-moral terms, what goodness consists in. As Gibbard puts it, the expressivist gives an *oblique* naturalistic explanation of morality. He rejects *straight* reductive naturalist attempts to reductively explain what makes it the case that something has the moral properties that it does, but explains why no such straight reductive naturalistic explanation of morality is needed. The expressivist can show that morality is in some sense continuous with natural science while rejecting any reductive explanation of morality. Gibbard argues that all that is needed for an oblique naturalistic explanation of morality is an expressivist treatment of language and thought about morality.

However, this style of explanation breaks down when applied to meaning. First of all, note that its starting point is the *semantic* thesis that meaning ascriptions do not describe, but express plans. This thesis concerns the *meaning* of a certain class of sentences – the semantic ascriptions. This thesis appears to commit the expressivist at least to the existence of one semantic property: the property of expressing a plan. A straight naturalist would attempt to give a reductive explanation of this semantic property, to explain what this semantic property consists in. But as an expressivist, Gibbard is committed to giving an oblique explanation of this semantic property which involves explaining why there is no need to postulate such a property in the first place. Gibbard might try saying that the expressivist's own claim that semantic statements express plans is itself an expression of a plan. But there are two difficulties with this move. First, it seems to give rise to a vicious regress of oblique explanation. Since the first-order claim that semantic ascriptions express plans committed the expressivist to the existence of at least one semantic property, the metalinguistic claim that the expressivist's first-order claim expresses a plan also commits him to the existence of a semantic property, and there is no explanation for why a straight reductive explanation of what this property consists in is put off indefinitely (see Hattiangadi, 2015).

Second, if the expressivist's central claim is indeed true, and all semantic statements express plans, then the expressivist's own claim that semantic statements express plans itself expresses a plan. But it is hard to see what bearing this has on the hard problem of intentionality. For, even if the expressivist expresses the plan to treat semantic statements as expressing plans, this does not entail that semantic statements do express plans. Consider the analogy again with morality. In the moral case, the expressivist's claim that moral statements express plans is naturally understood to describe the semantics of moral statements.

Given that this semantics is descriptively accurate, there is no need to postulate any moral properties to correspond to moral statements. In the semantic case, the expressivist must be understood to express a plan in claiming that semantic ascriptions express plans. But it does not follow from the expression of this plan that there is no need to postulate any moral properties (see Hattiangadi, 2015).[24]

So, expressivism does not offer a route to a satisfactory solution to Kripke's problem. This undermines Gibbard's central argument for the view that the concept MEANING is normative, which we already had independent reasons to reject.

6 Conclusion

In sum, we have seen that the normativity of meaning really has very little bearing on the hard problem of intentionality in any of the four senses given above. The view that meaning involves rule-following or a normative judgment of some kind is untenable, and in any case, has no bearing on the hard problem of intentionality. Both the hypothesis that meaning is a source of normativity and the hypothesis that meaning is determined by normativity might in principle have a bearing on the hard problem of intentionality. However, the view that meaning is a source of normativity is implausible, and there is little evidence that known difficulties with the reductive analysis of meaning can be resolved by adding normativity to the explanation. Finally, Gibbard's recent suggestion that the concept MEANING is normative is implausible and his proposed expressivist resolution of the hard problem of intentionality appears to be untenable.

Notes

1 I will adopt the convention of using small capital letters to denote concepts and thoughts.

2 This is what Kathrin Glüer and Åsa Wikforss call 'ME normativism,' or 'meaning-engendered' normativism.

3 I assume that to accept a sentence is either to assert it, assent to it, or to be disposed to do so.

4 This is much like the 'hard problem of consciousness' discussed by Chalmers (1996).

5 Though there are many ways to make supervenience more precise, I will assume that to say that the semantic facts supervene on the non-semantic facts is to say that any metaphysically possible world that is a minimal non-semantic duplicate of our world, is a semantic duplicate of our world, where a minimal non-semantic duplicate of our world is a world that satisfies all of the non-semantic truths and contains no 'extras' (cf. Jackson, 1998).

6 See Hattiangadi (2007), Finlay (2010). For a formal semantic account of norm-relative statements, specifically containing 'must' or 'can,' see Kratzer (1977; 1981). In Kratzer's semantics, norm-relative statements are treated as relational modal claims. They are statements of metaphysical necessity restricted in relation to two parameters: a modal base, W, the set of worlds consistent with everything that is believed as common ground in the context, and an ordering $\geq_o$ on W, the source of which, O, is in this case your desires, also made salient by the context. Thus, she says, 'it must be that p' is true iff p is true at every highest ranked world $w \in W$ (as ranked by O), 'it may be that p' is true iff p is true at at least one of the highest ranked worlds.

7 I use 'fact' and 'truth' interchangeably.

8 Thanks to Marianna Bergamaschi Ganapini for this suggestion.

9 It has been common in the discussion of the normativity of meaning to distinguish hypothetical or instrumental oughts from categorical oughts, and identify genuine normativity with the latter

(cf. Hattiangadi, 2006; 2007; Glüer, 1999; Glüer and Wikforss, 2010; Wikforss, 2001). Though it is clear that instrumental oughts are a class of norm-relational oughts, it is not entirely clear where categorical oughts fit in. The concept of a categorical ought goes back to Kant's categorical imperative, which itself is an absolute, unconditional requirement. However, if what you categorically ought to do is what you ought to do in view of a Kantian categorical imperative, then categorical oughts are norm-relational in my sense. In the contemporary discussion of the normativity of meaning, categorical oughts are often characterized simply as non-instrumental. But the class of norm-relative oughts is larger than the class of instrumental oughts, since some non-instrumental oughts – such as role-oughts and functional oughts – are non-instrumental but nevertheless norm-relational.

10 Anti-normativists have argued that the fact that I mean addition by 'plus' may be relevant to what I ought to do, conditional on the desire to speak truthfully (and other relevant background conditions), but this does not make this fact normative. By the same token, the fact that it is raining is relevant to whether I ought to take an umbrella when I go out, conditional on the desire to remain dry (together with relevant background conditions). And this does not make facts about the weather normative (Glüer, 1999; Hattiangadi, 2006; 2007; Wikforss, 2001). Verheggen's response to this objection is to argue that there is a disanalogy: instrumental semantic oughts are essential to meaning, whereas instrumental oughts about the weather are not. If it is false that if I want to tell the truth, then I ought to say '58 + 67 = 125,' then I do not mean addition by 'plus,' whereas if it is false that if I want to avoid getting wet, then I ought to take an umbrella, nothing follows about the weather. Yet, these cases seem to be parallel: if it is not the case that it is necessary to carry an umbrella in order to avoid getting wet, then holding other relevant background conditions fixed (I plan to go out of doors, I don't have a raincoat, rain makes you wet, umbrellas protect from the rain, etc.), it does follow that it is not raining. Furthermore, Verheggen's point does not speak to the objection: even if instrumental oughts are essential to meaning, they are not genuinely normative.

11 This is what Glüer and Wikforss (2010) call ME normativism.

12 Sometimes, norm-relational oughts are contrasted with the *all things considered* ought. But the concept of the all things considered ought seems to be norm-relational, since what you ought to do all things considered is what you ought to do, *in view of everything that is normatively relevant*. So, the concept of the all things considered ought is distinct from the concept of the unqualified ought. Nevertheless, it is plausible that the two concepts are co-extensive: necessarily, you ought to do A iff you ought to do A, all things considered.

13 A twist on this is the view that semantic truths can be reductively explained in terms of the normative and natural truths, but that the semantic facts supervene on the natural facts alone. We will consider one version of this view in the next section: Gibbard holds that semantic concepts are normative, but that they pick out natural properties.

14 Of course, it seems as though you are not disposed to respond with the sum in the evil demon case. On a very crude dispositional view, it would follow from this that you do not mean addition by 'plus.' However, an alternative explanation of the evil demon case is available. A more sophisticated dispositionalist might say that though you are disposed to respond with the sum whenever asked, this disposition is 'blocked' or 'masked' by the disposition to do what you think is morally required in the evil demon case.

15 It is controversial whether Davidson truly is a normativist (cf. Engel, 2001, and Glüer, 2001).

16 It might be tempting to defend Lewis's appeal to 'naturalness' as a solution to the permutation problem (cf. Lewis, 1983; 1984). However, we have assumed, for the sake of argument, that the permutation problem cannot be solved by recourse to the non-normative information alone. So we can set this kind of approach aside. Our question is whether the permutation problem can be solved if the radical interpreter is allowed recourse to some normative information.

17 Thanks to Alex Miller for pointing this out.

18 The first example occurs on p. 40 of Gibbard (2012), with minor stylistic variations, while the second is reconstructed from Gibbard's discussion of analyticity and synonomy in chapter 6. Some further examples occurring in the text are somewhat puzzling. For instance, Gibbard says: "I ought not to believe, all at once, that snow is white and that nothing is white – and that ties in with the meaning of our term 'nothing'" (Gibbard, 2012, p. 13). Even if it is true that I ought not to believe both that snow is white and that nothing is white, this seems not to have anything to do with the meaning of the term 'nothing.' For it is arguably true that Kaveri, a monolingual speaker of Konkani, ought not to believe both that snow is white and that nothing is white, yet it is difficult to see what this might have to do with the meaning of the English term 'nothing.'

19 Gibbard's claim is that the concept MEANING is normative, and this is how he suggests we might capture the normativity of this concept. Note that his view is not that all concepts, such as SNOW, WHITE, and so forth are normative. That is, it is not, according to him, grasp of these concepts that entails acceptance of the normative entailments involving them.

20 One might try to argue that he fails to grasp the concept of belief, because beliefs cannot be formed at will, but that would not help Gibbard in his efforts to argue that the concept of meaning is normative. In any case, Gibbard accepts that beliefs can be formed at will (Gibbard, 2012).

21 It is worth noting that Gibbard distinguishes between subjective and objective oughts: what you objectively ought to do is what you ought to do in light of everything that is the case, what you subjectively ought to do is constrained in some way by your state of information. He claims that semantic oughts are subjective oughts, which suggests that he would ultimately reject the implication from (1a) to (1b). He can thereby avoid the inconsistency between the two sets of analytic entailments. But he cannot thereby avoid the objections presented above, since those turn on the thought that one might sensibly reject either entailment without displaying conceptual confusion.

22 See, e.g., Glüer (1999), Glüer and Wikforss (2009), Hattiangadi (2006; 2009; 2007), Wikforss (2001). For a comprehensive review of the issue, see Glüer and Wikforss (2010).

23 Gibbard (2012, p. 16) distinguishes between a weak normativity thesis, according to which meaning ascriptions have normative entailments, and a strong normativity thesis, according to which the meaning of an expression is defined by the pattern of oughts it entails. Though Gibbard purports to defend both theses, it is only the weak normativity thesis that is relevant to the present discussion.

24 Of course, a cognitivist realist about normativity might claim that the concept of meaning is normative while rejecting an expressivist treatment of semantic normativity. So, the view that the concept of meaning is normative does not stand or fall with expressivism. However, a cognitivist realist about normativity who claims that the concept of meaning is normative would be committed to the view either that meaning is a source of normativity or that semantic facts are determined by normative (and natural) facts. Since I consider and reject those views separately, I set them aside in this section.

Indeterminacy of Translation

CRISPIN WRIGHT

W. V. O. Quine's contention that translation is indeterminate has been among the most widely discussed and controversial theses in modern analytical philosophy. It is a standard-bearer for one of the late twentieth century's most characteristic philosophical preoccupations: the skepticism about semantic notions which is also developed in Kripke's interpretation of Wittgenstein on rules (see Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING) and which many have read into Putnam's 'model-theoretic' assault on realism (see Chapter 27, PUTNAM'S MODEL-THEORETIC ARGUMENT AGAINST METAPHYSICAL REALISM). The more general concern reflected by these arguments is how space can be found for the reality of meanings – and indeed for other norms, like the ethical – in a world whose fundamentals, as the orthodox wisdom has it, are apt for complete characterization by the methods and vocabulary of physical science.[1]

If Quine's arguments succeed, this is not a concern which we should seek to allay, since there can be no satisfactory answer to it. At least, that will be the position if, with Quine, we take it that if translation is indeterminate, so is meaning itself, so that there are accordingly no genuine facts about meanings for a satisfactory world-view to accommodate. Quine envisages, moreover, that a consequential indeterminacy must spread outwards to infect ordinary "folk" or intentional psychology which comprises states, like beliefs and desires, which are in part identified by their content, as well as modal properties of statements, such as necessity and possibility, which functionally depend upon those statements' meanings (see Chapter 31, MODALITY). Much is at stake, then, in Quine's thesis.

The discussion to follow is organized as follows. §§1 and 2 will offer some initial reflections on the content and implications of the indeterminacy thesis, and of the presuppositions that Quine makes in treating it as a stepping-stone to semantic irrealism. §3 then distinguishes Quine's two principal arguments[2] for the thesis: the famous 'gavagai' argument ('from Below') of *Word and Object* (1960), and the argument ('from Above') from the underdetermination of empirical theory by data emphasized in "On the reasons for the indeterminacy of translation" (1970), and lays out the essentials of the former.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

§4 appraises this argument in the light of Gareth Evans's discussion in his "Identity and predication" (1975). §5 assesses the cogency of Evans's objections. §6 turns to the second and more radical argument, laying out certain basic distinctions and implications; and §7 is concerned with its appraisal.

Quine's contribution to these issues is, in effect, no less than to have invented them and to have set the agenda for all subsequent discussion. He has continued a vigorous engagement in that discussion, and students of some of his more recent contributions, for instance in *Pursuit of Truth* (1990) or the "Three indeterminacies" paper (1989), will have noted significant developments and changes of emphasis. But these are beyond the purview of this chapter, whose concern is not with scholarship of the perhaps revisionist tendencies of Quine's more recent thought, but simply with the structure, power, and philosophical background of the classic Quinean arguments.

1 What Does the Indeterminacy of Translation Involve?

It's commonplace that expressions in one language may resist a fully satisfactory translation into another: that there is, for instance, no exact English equivalent, capturing all its existentialist overtones, of the French *ennui* (a kind of jaded detachment), or the special piquancy of the German *Schadenfreude* (a form of pleasurable excitement at another's misfortune). This commonplace has little to do with Quine's thesis. Quine's claim is not that exact translation is sometimes impossible, but that *there is no such thing as* exact translation: that for any expression, in any language, there will inevitably be a range of alternative translations of it into any particular language each of which, in conjunction with coordinating adjustments in the translation of other expressions, will equally well – and *unimprovably* – accommodate all the behavioral data concerning speakers' use of the translated language.[3]

Quine argues his case for this thesis in the context of *radical* translation. Radical translation is the translation of a hitherto wholly untranslated language, about whose syntax, semantics, and etymology we are in a position to make no prior assumptions whatever. All we are assumed to have to go on is our observation of the use of the language. More specifically: we are assumed to be able to identify behavior on the part of its native speakers which constitutes assent to and dissent from particular utterances in the language, and we are assumed to be able to observe the circumstances in which such assent or dissent takes place. We are also allowed to suppose that we are able to interact with native speakers in particular contexts, to put utterances to them in their own language for assent or dissent, and in general to encourage the production of evidential data for our translation, rather than merely passively observe. Quine's claim is that if a project of translation is undertaken under these circumstances, then there are bound to be intuitively incompatible claims about the meanings of (what we identify as) expressions in the natives' language such that, no matter how extensive the data which we proceed to gather, it will in principle never give us a reason to prefer one such claim to another.

Why, it may be wondered, the focus on radical translation? Why is the situation of someone engaged in so unusual a project, on so impoverished a basis of collateral information, of particular interest? Well, consider how it might be that radical translation was indeterminate, yet *non-radical* translation in certain cases – say the translation of some parts of French into English – was a fully determinate matter. There's no doubt that in

translating a French utterance into English, we will make all kinds of assumptions – about the accuracy of dictionaries, the context, the purposes of the speaker, and so on – which effectively may uniquely determine the translation of a particular word in it. But what *justifies* these assumptions? Quine's thought is that their justification would ultimately have to come back to what could be appreciated from the vantage point of the radical interpreter: that anything we – kindred post-Roman Europeans – can properly be said to *know* about French would have to be accessible, at least in principle, to a Martian radical translator of French – always provided the Martian was a good enough linguist and had enough time to gather the relevant observations. For Quine, any presuppositions we make when translating familiar languages into other familiar languages count as items of known fact – in contrast to, say, convention – only if they could in principle be justified by the methods of radical translation. So if radical translation is indeterminate, then all translation is indeterminate in the sense that the choice between alternative schemes of translation may be beyond justification by appeal to anything factual – anything which may be, properly speaking, known.

As remarked, Quine's view is that it follows from the indeterminacy of translation that meaning itself is indeterminate: if there are no facts of the matter about how an expression may be correctly translated into another language, then there are no facts of the matter about what it means. That may seem a natural enough transition. But it depends, of course, upon an additional assumption: that there can be no facts about meaning which are not accessible to a radical interpreter. And that would seem to involve presupposition of two further, potentially contentious theses:

(1) That there is no first-/third-person asymmetry in the epistemology of understanding: that I can know nothing about what I mean by some particular expression unless you can know it too, by sufficient observation of my linguistic behavior – although it seems clear that, in the typical case where I do know what I mean by an expression, I do not know it by observing my own behavior.[4]

(2) That whatever 'methodology' reconstructs a child's actual learning of a first language, the harvest of that methodology – the understanding of meanings in which pursuit of it results – cannot be *richer* than that of the methodology of radical interpretation. For if it were, there would be a way of knowing facts about meanings which radical interpretation couldn't emulate.

Point (1) may seem attractive, as being merely a version of the thesis that one's meanings must be, in principle, publicly available to others – the thesis of the essential manifestability of meaning which is widely accepted in contemporary philosophy of language (for further discussion, see Chapter 20, REALISM AND ITS OPPOSITIONS; Chapter 11, MEANING AND PRIVACY, and Chapter 12, TACIT KNOWLEDGE). But point (2) may seem less obviously agreeable: doesn't it simply overlook the consideration that the actual learning of a first language may deploy any number of unlearned dispositions – including 'grammatical' dispositions, if Chomsky is right, and also what we might call 'similarity dispositions,' that is, dispositions to find certain aspects of similarity in presented material salient and others not so – of which the methodology of radical translation, if it is characterized along the above austere lines, will take no account?

Each of these reservations would require extended discussion before a considered verdict could be reached on Quine's passage from indeterminacy of translation to irrealism about

meaning. But for the purposes of what follows, we will assume that points (1) and (2) are each sound, and will not pursue such reservations further.

2 Could One Live with the Indeterminacy of Translation?

Let us (provisionally – there are a number of distinctions to be drawn here, which we shall come to below) formulate the thesis as follows:

> For any expression used in a given language, there are at least two incompatible hypotheses about its meaning which equally well – and *unimprovably* – explain all observable aspects of its use in that language.

Suppose this is accepted, and that we are content to conclude from it that, for any two such unimprovable hypotheses about an expression's meaning, there is no fact of the matter as to which of them is correct. Still, it wouldn't seem to follow that there are no facts about meaning at all. The undecidability of the choice between two unimprovable hypotheses is quite consistent with its being definitely *wrong* to choose any of a large number of incompatible alternative hypotheses; the unimprovable hypotheses may be definitely superior to the rest of the bunch, even if the choice between them is underdetermined. So we need to distinguish between weak and strong versions of the indeterminacy thesis:

> *Weak* versions will contend that *some* questions about the meaning of an expression are indeterminate;
> *Strong* versions of the thesis will contend that *all* questions about the meaning of an expression are indeterminate.

Even if we allow that indeterminacy of translation does indeed entail indeterminacy of meaning, it is clearly a strong thesis that is needed if we are to conclude that there are no facts whatever about meaning.

Now, the strong thesis certainly does seem disconcerting; but we should distinguish between better and worse reasons for finding it so. A bad reason would be the thought that all language becomes simply meaningless if we have to take it that meaning is everywhere indeterminate. That's just a confusion: *meaninglessness* is itself a specific–determinate–semantic condition. If there are no determinate facts about meaning, there are no determinate facts about meaninglessness either. But better reasons for disquiet are not far to seek. First, there is the fact that ordinary psychological states, like belief, desire, fear, and so on, which feature so pervasively in our thought about ourselves and each other, are identified by their content: any belief is the belief that p, for some p; any desire is the desire that q, for some q. If there are no facts about the meanings of linguistic expressions, the question immediately arises, how could there still be determinate facts about the content of such states? How could *psychological content* survive an argument which was generally destructive of *linguistic content*? But if it cannot, then it seems that the whole fabric of ordinary psychological explanation must collapse.

Second, if there are no facts about meaning, how can there be facts about *truth*? Our ordinary thinking ascribes truth and falsity to various things: to declarative sentences, to propositions, and to beliefs. But the latter now come under the general shadow which, as

just noted, Quine's thesis casts over the intentional-psychological; and one who regards meaning as strongly indeterminate is hardly likely to be well disposed towards propositions – that is, *reified linguistic contents*. So it is declarative sentences, it seems, which will have to be the canonical bearers of truth-values in the Quinean scheme of things. But then there is the obvious difficulty that the truth-value of a sentence functionally depends both on the way the world is and on its *meaning*. If there are no determinate facts about meanings, it would appear to follow that truth-values are indeterminate as well.

As remarked, Quine himself has not shrunk from the scorn of intentional psychology to which his position appears to commit him.[5] But the concern about the availability to him of ordinary notions of truth and falsity is quite another matter. If strong indeterminacy is sustained, the truth-value of a sentence – if the notion remains legitimate at all – will have to be determined by factors independent of meaning as traditionally understood. A program of naturalized semantics might conceivably prove to be at Quine's service here (see Chapter 8, A GUIDE TO NATURALIZING SEMANTICS), though the prospects for such programs seem anything but encouraging. This difficulty for Quine seems never to have been properly addressed.[6]

3 Quine's Arguments for the Indeterminacy Thesis

Quine has presented two main and quite different styles of argument for the indeterminacy thesis. What has come to be known as the Argument from Below tries to illustrate the predicament of the radical translator by presenting actual concrete alternative translations of certain expressions between which, no matter what behavioral data might be accumulated, it will never be possible to choose rationally. The Argument from Above[7] proceeds, by contrast, on a purely theoretical basis, from the thesis (henceforward the Underdetermination Thesis) that all empirical theory construction is in principle underdetermined by all available data. This second form of argument, in which Quine himself invests the greater confidence,[8] will show, if successful, that translation, and thereby – so we are now allowing – meaning, must be indeterminate even if we lack the wit to construct in detail the sort of illustrations of indeterminacy of which the Argument from Below seeks to provide some examples. In this section we will review some of the twists and turns pursued by the development of the Argument from Below.

As emphasized, Quine is content to grant to the radical interpreter the ability to recognize native speakers' assent to and dissent from sentences formulated in their language, and the ability to interact with them at least to the extent of eliciting assent to or dissent from particular such sentences. In consequence, the translator will be able – except in the most recalcitrant case – to arrive at empirically confirmed generalizations about which types of situation provoke assent to or dissent from instances of a particular sentence-type. Now Quine is content, in *Word and Object*, to resurrect a surrogate for the notion of synonymy which, in "Two dogmas of empiricism," he so roundly rejected: two sentences are said to be *stimulus synonymous* just in case assent to and dissent from them is provoked by the same sensory circumstances. The central contention of the Argument from Below is accordingly that, no matter how ingenious, the translator will never be able to decide rationally between stimulus-synonyms just on the basis of observation of the native speakers' linguistic behavior. Yet intuitively, stimulus-synonyms may be very different in meaning; indeed, they may not even coincide in extension.

Suppose, to follow in the tracks of Quine's famous example, that a rabbit hops past and the translator hears the natives say, "gavagai." Subsequent investigation discloses that the natives are generally disposed to assent to "gavagai" when rabbits are visibly present, and to dissent from "gavagai" when there is no sign of rabbits. So the translator tentatively notes down the translation of "gavagai" as "Lo! a rabbit" or "There goes a rabbit," or something of the sort. That may seem to be a well-grounded translation, but there are in fact a variety of alternatives which the translator would seem thereby to have overlooked. There are, that is, a number of concepts besides *rabbit* which, in exhibiting the observed patterns of assent and dissent, the natives could just possibly be exercising. Some of these are, respectively, the concepts of:

undetached rabbit part,
instantaneous temporal stage of a rabbit,
rabbithood (the universal),
rabbit-fusion (the scattered physical aggregate of all rabbits), and
rabbiting (taken as analogous to the feature-placing concepts, *thunder* and *rain*).

And the one-word utterance "gavagai," could correspondingly mean any of:

There is an undetached rabbit part.
There is a temporal stage of a rabbit.
Rabbithood is instantiated over there.
There is a part of the rabbit-fusion.
It's rabbiting.

The point Quine is making is not merely that the finiteness of the translator's observations must leave open alternative interpretations. The contention is not merely that, however much data the interpreter gathers, there will be rival translational hypotheses which are consistent with it. It is stronger; namely, that there are *certain specific* translational hypotheses such that, however much data the interpreter gathers, each will remain in play if any does.

Now it's clear – however peculiarly the various mooted translations of "gavagai" may strike us – that Quine's point is correct so long as the data to be considered concern nothing but the conditions which prompt assent to and dissent from the one-word sentence "gavagai." However, the thought immediately occurs that the situation is bound to change for the better as soon as we consider more complex sentential constructions in which "gavagai" features as a constituent. For example, suppose we are in a position to put the question, "How many gavagai are there over there?" or "Is that the same gavagai that we saw five minutes ago?" Then the correct answers are bound to vary according to whether or not "gavagai" means: *rabbit*, or: *undetached rabbit part*, or: *stage of a rabbit*, respectively. For one rabbit is many undetached rabbit parts; and stages of a rabbit, unlike rabbits themselves, have no temporal duration.

Quine's reply to this (Quine, 1960, pp. 71–72) is that our ability to run these tests will, of course, depend on our having independently translated certain constructions of the native language as meaning "how many" and "is the same … as." And, he contends, it is quite unclear how one might go about settling the translation of such expressions without *first* settling the interpretation of words like "gavagai" – that is, of sortal predicates – and without identifying the natives' numerals.

That gives pause. Isn't he right? Suppose, for instance, the natives use a word, "qua," which we have come to suspect may be used in concatenation with sortal predicates to ask "how many?" questions. How could we test this hypothesis unless we *already* knew the meanings of a range of such predicates with which it might be concatenated to ask such questions, and could tell whether the answers were as would be appropriate if "how many?" questions were indeed what "qua" was enabling us to put? Indeed there is a further, more specific difficulty. Suppose we have indeed somehow correctly identified the numerals in the natives' language, so that we can tell when the natives are telling us that there is one of a certain kind of object, or three, and so on. And suppose we have settled on the translation of the word "qua," as it occurs in constructions like "qua gavagai," as meaning something like "how many?" And imagine that we put the question, "qua gavagai?" when a solitary rabbit is visible, and get an answer which we rightly take to mean "one." Even so, it is too quick to suppose that the translation of "gavagai" as *undetached rabbit part*, is thereby defeated. It is defeated, of course, if "qua" does indeed precisely mean: *how many?* But "qua gavagai" could, consistently with its eliciting the same answers as "how many rabbits?" mean not that but rather: *Of how many rabbits are there undetached parts over there?* More generally, its role could be this: that if F means *undetached G-part*, then "qua F" means: *Of how many Gs are there undetached parts there?* Under that hypothesis, what looked like a crucial experiment ceases to be so.

Quine's contention, in general, is this: if a pair of expressions have the same stimulus-meaning, then even if they intuitively differ in meaning in ways that would impinge differentially on the use of more complex contexts in which they occur, there will always be a *compensating adjustment* to the interpretation of the surrounding context of such a kind that, under the adjustment, the uses once again coincide. More formally: if F and G have the same stimulus-meaning, but differ in intuitive meaning – like "rabbit" and "undetached rabbit part," for instance – in such a way that, with respect to a particular embedding context, "**Φ**…," the patterns of assent to and dissent from "**Φ**F" and "**Φ**G" could be expected to differ, there will always be an adjusted interpretation of "**Φ**…" such that the assent/dissent conditions of "**Φ**G" under the adjustment will coincide with those of "**Φ**F" when unadjusted.[9]

4 Evans's Appraisal of the Argument from Below

This line of thought, as it stands, is arresting, but hardly sufficiently developed to count as cogent. It deserves thinking through in detail, yet there are few attempts to do so in the secondary literature. However, a distinguished exception is provided by Gareth Evans's paper, "Identity and predication" (1975). Evans contends that Quine looks in the wrong place for considerations that might prove the superiority of the translation of "gavagai" as *rabbit*. Quine's consideration of contexts in which "gavagai" might occur embedded is restricted to what he calls the "apparatus of individuation" – constructions involving identity, plurals, and the numerals. He allows that if we somehow fix on a translation of certain of the natives' expressions within this apparatus, then it will be possible to construct contexts which will discriminate, in principle, among the stimulus-synonyms of "rabbit." His point, then, is that the translation of native expressions into elements of the apparatus of individuation presents a problem which is *coordinate with* that of the translation of "gavagai," and that it is in principle impossible to motivate

the identification of certain native devices as expressing plurality, identity, and so on, without first fixing the translation of terms like "gavagai." Evans's counter is that we do not actually need to consider the apparatus of individuation at all; rather it can suffice to consider how predicates may be used *in combination*, and how they behave under negation.

Here is an illustration of the sort of thing Evans has in mind. Suppose we have identified two other words in the native language, "odolby," and "thewi," which we observe to be associated with the following patterns of assent in the native speech community:

> There is assent to the one-word sentence "odolby" just when something bloodstained is visible.
> There is assent to the one-word sentence "thewi" just when something white is visible.

In addition, suppose we have observed the use of a particle, "neg," which seems to act as an operator of negation; that is, we observe:

> There is assent to "neg gavagai" just when no rabbit is salient;
> There is assent to "neg thewi" just when nothing white is salient;

and so on. And now suppose we also observe the following more complex patterns of linguistic behavior:

> Situations which prompt assent to "gavagai" and "thewi" do not always prompt assent to the conjoined construction, "thewi gavagai." The latter is assented to only when a white rabbit is salient. "Thewi" and "gavagai" will, however, be assented to individually when a brown rabbit sits on the snow.
>
> It is similar with the conjoined constructions "odolby gavagai" and "odolby thewi" – they are assented to only when a bloodstained rabbit is salient, or when something is salient which is both white and bloodstained.[10]
>
> Likewise, the natives are disposed to assent to "thewi gavagai" and "odolby gavagai" when two rabbits are in view, one white, the other bloodstained; but they will assent to "odolby thewi gavagai" only when one and the same rabbit is both white and bloodstained.

Evans's thought is that observations of this character would suffice to eliminate some of the stimulus-synonyms of "rabbit" as adequate translations of "gavagai." For instance, if "gavagai" really were just a device for reporting an environmental feature – like "it is raining" – and "thewi" were the same, then it would seem to be impossible to interpret the conjoined construction "thewi gavagai" as anything other than the conjunction of the ingredient claims: it is whiting and it is rabbiting (compare: it's windy and it's raining). And that translation cannot account for the fact that "thewi gavagai" is not assented to unless the "whiting" is restricted to the surface of a *rabbit*.

The translation of "gavagai" as *undetached rabbit part* also seems to be in difficulties under the hypothesized data. What are we to say that "thewi" means in that case? If it just means *white*, then "thewi gavagai" ought to be assented to whenever a rabbit is salient with an undetached white part – say, a white foot. But that isn't what happens. If the one-word sentence "thewi" means *undetached part of a white thing*, on the other hand, then again

"thewi gavagai" ought still to be assented to when the white-footed rabbit presents himself, since his toes are undetached parts of a white thing, namely his foot. So that translation fares no better. We might surmount that difficulty by allowing "thewi" to mean *undetached part of a white rabbit*; but then we'd be at a loss to understand the natives' assent to it as they gaze at a snowy but rabbit-free landscape.

"Undetached rabbit part" and "temporal stage of a rabbit" are, like "rabbit," and unlike the feature-placer, "rabbiting," sortal predicates. By contrast, the other items on Quine's list of stimulus-synonyms for "rabbit," that is, "rabbithood" and "rabbit-fusion," are singular terms, standing respectively for an abstract and for a scattered concrete object. It is these interpretations of "gavagai" which, Evans contends, are put in difficulty by the kind of data which he envisages for the natives' particle of negation. Suppose our observations disclose that the assent conditions of compound sentences vary depending on the position within them of "neg"; for instance

> "neg thewi gavagai" is assented to whenever no white rabbit is in view, including the case when no rabbit of any kind is in view, whereas "thewi neg gavagai" is assented to only in the presence of rabbits of other colors.

These facts are nicely explained if we suppose that "thewi" means white, "gavagai" means rabbit, and "neg" functions as a device of sentential negation when it takes initial position, and as a device of predicate negation when it immediately succeeds a predicate.[11] But how are the data to be accommodated on the assumption that "gavagai" is, for example, a singular term standing for the universal, rabbithood? On that assumption, the assent conditions of "thewi gavagai" suggest that "thewi" is a predicate of universals roughly equivalent in meaning to "has a white instance here." But in that case we seem to have no way of generating a sentence with the assent conditions hypothesized for "thewi neg gavagai." For the negation particle has nothing smaller to operate on, so to speak, than an atomic predicate of the natives' language; and when it is so restricted, to suppose that it occurs as a predicate negation in that sentence is to predict, falsely, that the sentence should have the assent conditions of "rabbithood does not have a white instance here" – something which should be assented to when there is no rabbit to be seen.

An analogous problem would presumably confront the translation of "gavagai" as *rabbit-fusion*, could we first but find a workable construal in this case of "thewi" as it occurs in sentences like "thewi gavagai." But in fact, as Evans points out, this translation of "gavagai" also inherits the problems associated with the translation *undetached rabbit part*. If "thewi" is a predicate of concrete but spatio-temporally scattered entities, what hypothesis about its meaning will get the assent conditions of "thewi gavagai" right? Not "… has a white part here" – because brown rabbits with white tails don't provoke assent to it – nor even "… has a white, rabbit-shaped part" – because that would leave us bereft of any explanation of the natives' assent to "thewi todagai" in the presence of an Arctic fox.

So far so good, it may seem. Different considerations come into play when Evans comes to the proposed translation *temporal stage of a rabbit*. The sort of difficulty he finds for this proposal (see Evans, 1975, pp. 360–361) is not posed by envisaged data of the foregoing kinds, but has to do with the interpretation of what, in our preferred translation scheme involving rabbits, whiteness, and the rest – henceforward the *favored scheme* – we will naturally take to be simple *tensed* assertions. Suppose, for instance, that the suffix "-p" is naturally taken, in that scheme, as an indicator that a predication is past-tensed.[12]

The question Evans raises is how such data is to be accommodated by a translation scheme for the natives' language which treats the predicates in question as predicates of temporal stages.

Evans's (rather terse) discussion here is semi-technical. He envisages an interpreter who is working within something like the framework of a Tarski–Davidson recursive theory of meaning (see Chapter 2, MEANING AND TRUTH-CONDITIONS: FROM FREGE'S GRAND DESIGN TO DAVIDSON'S) and who first lays down basic clauses which stipulate satisfaction conditions for *tenseless counterparts* of the natives' predicates; for instance

⟨x, t⟩ satisfy "odolby" (tenseless)[13] ↔ (∃y) (y is bloodstained at t & x is a stage of y)

– a pair consisting of a temporal stage, x, and a time, t, satisfy "odolby" if and only if that stage is a stage of something which is bloodstained at that time, and then stipulates satisfaction conditions for stages and tensed versions of those predicates in terms of these basic clauses; for instance, for the simple present tense (where t_u is the envisaged time of utterance)

x satisfies "odolby" (present tensed) ↔ ⟨x, t_u⟩ satisfy "odolby" (tenseless)

– a stage satisfies (present tensed) "odolby" only if the pair consisting of that stage and the time of utterance satisfies (tenseless) "odolby"; and for the simple past tense

x satisfies "odolbyp" ↔ (∃t′) (Before t_u, t′ & ⟨x, t′⟩ satisfy "odolby" (tenseless))

– a stage satisfies "odolbyp" if and only if there is a time earlier than the envisaged time of utterance such that the pair consisting of that stage and that time satisfies (tenseless) "odolby."

Now, an evident effect of the proposed base clause is that *every* stage, x, in the life of a rabbit which is bloodstained at t will be such that ⟨x, t⟩ will satisfy (tenseless) "odolby." So any treatment of the tenses along these lines will have the consequence, as Evans observes, that if any temporal stage of a given rabbit satisfies "odolbyp," or (present-tensed) "odolby," then *every* temporal stage of the same rabbit, *no matter when occurring*, will satisfy "odolbyp," or "odolby" – and indeed will satisfy any other tense of the same predicate, if introduced via a clause along the same lines. Evans evidently regards this kind of promiscuity as a decisive difficulty, for he immediately moves to consider a proposal fashioned to avoid it. But he does not say why. We will return to the matter.

The second proposal Evans considers avoids the promiscuity by an obvious modification in the form of the base clauses; thus

x satisfies "odolby" (tenseless) ↔ (∃y)(∃t)(y is bloodstained at t & x is a stage of y & x occurs at t)

– a stage satisfies (tenseless) "odolby" if and only if it is a stage of something *which is bloodstained at the time at which that stage occurs*. Clauses for the simple present and past tenses may then proceed:

x satisfies "odolby" (present tensed) ↔ x satisfies "odolby" (tenseless) & x occurs at t_u

– a stage satisfies (present-tensed) "odolby" if it occurs at the time of utterance and is a stage of something that is bloodstained at the time that stage occurs; and

x satisfies "odolbyp" ↔ (∃z)(∃t′)((Before t_u, t′) & (z occurs at t′) & (x occurs later than t′) & (x and z are stages of the same thing) & (z satisfies "odolby" (tenseless)))

– a stage satisfies "odolbyp" if it is a later stage of something one of whose earlier stages, occurring before the time of utterance, is a stage of something bloodstained at the time it occurs.

However, Evans foresees a new difficulty for this scheme. According to the proposed clauses, "odolbyp gavagai" should be true just of stages of a rabbit occurring later than a stage in its life when it was bloodstained. What if there no longer *are* any such stages? What if, rather than clean up the bloodstained rabbit, we had destroyed it? In that case, the proposed clause will predict that the natives will no longer assent to "odolbyp gavagai," for there are now no stages to meet the specified condition. But it is easy to imagine how, consistently with the other data envisaged, they might nevertheless give their assent. We have only to imagine that their assent conditions for "odolbyp gavagai" coincide with those of the English sentence, "a rabbit was bloodstained." Evidence of that coincidence, it might seem, would then be powerful evidence for the favored scheme as against the temporal stage-scheme.

5 Are Evans's Objections Compelling?

Seemingly the least cogent part of Evans's discussion is his treatment, just reviewed, of the temporal stage-scheme. Even if the detail of his objections were wholly convincing, there would have to be a vague worry whether the problems thereby disclosed for the stage-theorist were not artefacts of avoidable features of the mooted Tarski–Davidson style of semantic-theoretical treatment of tense. But the detail does not seem convincing in any case. The last consideration, that the proposed clauses cannot recover the assertibility of "odolbyp gavagai" in circumstances when no stage of the rabbit in question post-dates its (last) bloodstained stage,[14] seems crucially to overlook an ambiguity in the hypothesized English (stimulus-)equivalent, "a rabbit was bloodstained." The English sentence can, indeed, be read as embedding a past-tensed predication – when it is taken as the existential generalization, for example, of "that rabbit over there was bloodstained," so that the tensing is done, as it were, within the scope of the quantifier. But the reading germane to Evans's possibility, when "a rabbit was bloodstained" is asserted of a now defunct rabbit, reverses the scope-priority: the past tense is now the principal operator in the sentence, and the quantifier occurs within its scope, so that the effect of the claim is rather that *it was the case that*: [a rabbit is bloodstained]. Any semantic treatment of tense which treats the tenses as operators – on tenseless sentences, in the kind of treatment Evans has in mind, but there are other possibilities – has to be open to all the usual possibilities for ambiguity in the scope of such operators. In particular, we have to expect wide and narrow scope possibilities broadly analogous to those presented by negation. The mooted clause for "odolbyp" is a proposal for a *past-tensed predicate*, where the tense operator is given narrow scope. Evans's objection to it, by contrast, is – irrelevantly – that it does not enable us to recover the (apparent) truth-conditions of predications of "odolbyp" in which it is not merely the predicate but the *whole sentence* that falls within the scope of the past tense. The objection is irrelevant because – their

overt form notwithstanding – such sentences should no more be construed as containing the kind of use of "odolbyp" which the proposed clause concerns than "it is not the case that a rabbit is white" should be construed as containing an occurrence of "is not white." The favored scheme, too, will have to cope with this kind of ambiguity; however it does so, there is no reason to think that the stage-theorist will not have exactly analogous resources.

In any case, what exactly was the problem that moved Evans to dismiss the first form of proposal? Why should the kind of promiscuity imposed by the originally mooted clauses be held to be objectionable? The point might seem obvious. Consider the blood-soaked rabbit of note 12 who gets a thorough cleaning. Suppose the natives assent to "odolby gavagai" before the washing, *but not afterwards*. How, if they are talking about temporal stages of the animal, and if "odolby" has the satisfaction conditions outlined, is this to be explained? If any temporal stage of the rabbit satisfies the utterance of "odolby" before the washing, then all do, no matter when they occur or when the question is raised. So why – if they are talking about properties of temporal stages – do the natives, having earlier assented to "odolby gavagai," not do so later? To be sure, the reference of "gavagai" will then be presumably to stages of the rabbit which post-date its bloodstained period. But, on the treatment proposed, that should make no difference. Since the natives cannot plausibly be taken to have forgotten that the rabbit was bloodstained, or not to have noticed, their temporally selective assent patterns – the very things that motivate viewing them as deploying tenses in the first place – are seemingly at odds with the ascription to them of an ontology of stages and the proposed semantic clauses for "odolby."

This train of thought, however, confuses the form of promiscuity actually entailed by the original type of clauses – promiscuity over stages, as it were – with a form of promiscuity over times. The key point is that those clauses have to be read as dealing with the satisfaction conditions of actual or envisaged *token utterances* of the tensed predicates they concern; that is the effect of their reference to a time of utterance, t_u.[15] The generalization they actually entail is that if a particular (actual or envisaged) historic token of (present-tensed) "odolby," or "odolbyp," is satisfied by a particular stage in the life of a rabbit, then it is satisfied by all earlier and later stages in the life of that rabbit. That is not to be confused with anything which generalizes from a particular historic token predicate's satisfaction to the satisfaction of other tokens of the same type uttered at *other times*. Nothing of that kind follows from the clauses in question when properly construed. In particular, they entail nothing about whether if a particular token of "odolby" is satisfied by a present stage of a rabbit, then that or later stages of the same rabbit should be regarded as satisfying *a later tokening* of "odolby." So there is nothing in the clauses to jar with the natives' hypothesized unwillingness to apply "odolby" to what they know to be a formerly, but no longer, bloodstained rabbit.[16]

I am not suggesting that Evans himself was guilty of this confusion, only that one who did fall into it might find a spurious plausibility in Evans's brisk dismissal of that particular approach on behalf of the stage-scheme – and that I am not sure what else he may have had in mind.

In any case, it must be reckoned as doubtful how forceful are Evans's objections to the temporal stage-scheme. The matter would assume some importance as far as the Argument from Below is concerned if Evans had indeed disposed of Quine's other mooted translation schemes, since the temporal stage-scheme would then represent the argument's last chance, at least as far as Quine himself develops it. But at least one recent commentator has questioned quite generally whether Evans's considerations really are successful (Hookway, 1988, chapter 9). A closer review of the matter will turn out to render further discussion of the temporal stage-scheme unnecessary.

Consider again the data envisaged in order to make trouble for the other schemes. For instance, a brown rabbit with a white foot provokes assent to "thewi" and "gavagai" separately but not to the compound "thewi gavagai." Evans challenges Quine to find an interpretation of "thewi," within the framework of an ontology of undetached parts of things, which explains this. Neither "… is white" nor "… is part of a white thing" will do; "… is part of a white rabbit" – or, more generally, "… is part of a white animal" –would explain why the compound sentence doesn't get assented to in the circumstances described; but it would leave us bereft of any explanation why "thewi" gets assented to on its own in the context in question.

There is an obvious counter. Evans is assuming that we have to find *some one general account* of the meaning of "thewi" to account for both simple and compound occurrences of it. But why shouldn't its syntactic/semantic role be *context-sensitive*? It could, for instance, mean *white*, when occurring in one-word sentences, but *undetached part of a white F*, when occurring in immediate concatenation with the word whose correct translation when not so concatenated is *undetached F-part* (and whose role, when conjoined with "thewi," accordingly reduces to that affixing the parameter, F). Context-sensitive variation in meaning, contrasting with simple ambiguity in so far as the meanings in question are variously cognate to each other, is a familiar phenomenon in natural languages; think, for instance, of the expression "fix" as it occurs in "I'll fix lunch," "he fixed the puncture" and "they fixed the race." Why should not phenomena of that general sort be found in the natives' language too? In effect what would be postulated would be a theory according to which "thewi" had a kind of ambiguity, albeit one in which there was a close relation between its diverse meanings, and where precisely which meaning it took would be determined by its syntactic mode of occurrence. But that doesn't seem outlandish really.

It is similar with the data concerning the use of "neg," represented by Evans as scotching the interpretations of "gavagai" as a singular term standing respectively for rabbithood and the rabbit-fusion. The problem was to find an interpretation of "thewi" which, when "neg" can occur both as external and as internal negation, would rationalize a native's assent to "thewi" when a white rabbit is salient, but to "thewi neg gavagai," when, say, brown rabbits are salient, and to neither when no rabbit is salient. The interpretation "… has a white instance here" captures the first datum; but if "neg" is a device of internal negation, it mis-predicts the assent conditions of "thewi neg gavagai." But again, the obvious rejoinder is that we are not constrained to take "neg," occurring as illustrated, as a device of internal negation in the first place. There could be an operator which, in prenex position, functions as sentential negation, but when it occurs as a predicate-suffix, serves not to negate the predicate – to generate its complement – but operates rather *within* that predicate's content. In particular, under the translation scheme which treats "gavagai" as a singular term standing for a universal, the role of "neg" occurring as suffix may be taken as one of generating the complement of the *adverb* – the mode of instantiation – which we interpret predicates like "thewi" and "odolby" as ascribing. So "thewi neg gavagai" is interpreted as saying not that rabbithood doesn't have a white instance here, but that it has a non-white instance here (as it were, *is instantiated non-whitely here*) – precisely what is wanted to save the data described.

How are we to assess the resulting dialectical situation? It is difficult to see one's way clear to the conclusion that *any* pool of data which a sympathizer with Evans might construct, and which would be *prima facie* recalcitrant for Quine's alternatives to the favored scheme, could be handled in the quite simple kinds of way illustrated. But what is surely convincing in advance is that the most that the sympathizer with Evans is going to be able to do is to call attention to possible observational data which wouldn't square with *particular*

proposed interpretations of some of the expressions concerned; and that it must always be possible in principle to handle such data if one is willing to assign a *variety* of syntactic roles, and/or semantic ambiguities, to the expressions in question. Does this reflection suffice to show that Evans embarked on a lost cause?

It does not. Consider this case. Suppose that alternative schemes along Quinean lines can indeed be constructed which can survive any envisageable addition to our pool of linguistic data, but that whereas the Quinean schemes survive by the postulation of ambiguities of various kinds, the favored scheme has, by and large, no need for such recourse. Then the latter would be, in a clear sense, *simpler* than the Quinean alternatives. Now, the point is well taken that simplicity cannot be assumed, without further ado, to be an *alethic* – truth-conducive – virtue in empirical theory generally. There is *prima facie* sense in the idea that of two empirically adequate theories, it might be the more complex that is actually faithful to the reality which each seeks to circumscribe. But the thought that, when it comes to radical interpretation, there is an ulterior psychologico-semantical reality which an empirically adequate translation scheme might somehow misrepresent is, of course, exactly what Quine rejects – exactly what he famously stigmatizes as the myth of the semantic museum (Quine, 1969, p. 27ff.). And with that rejection in place, methodological virtues which are not, in realistically conceived theorizing, straightforwardly alethic can now become so. In such cases, the methodologically best theory ought to be reckoned true just on that account. It is therefore not enough for a defender of Quine to seek to save the alternative schemes by postulations which, though still principled and general, are comparatively expensive in terms of ambiguity and other forms of complication. If a simpler scheme is available, that fact is enough to determine that these alternatives are *untrue*, by the lights of the only notion of truth that, in Quine's own view, can engage the translational enterprise.

It's another question whether the particular moves I envisaged fall foul of this point. The alternative interpretation of "neg" just canvassed, for instance, postulates a syntactic ambiguity only where the favored, internal/external negation distinguishing interpretation *already* does so, albeit a different ambiguity. And the interpretation of "thewi" – *undetached part of a white F* – to which we had the undetached-parts theorist resort in the attempt to accommodate Evans's assent-data for "thewi gavagai" might actually serve well enough to accommodate the natives' assent patterns to the one-word sentence "thewi" as well ("undetached part of a white something").

That, however, brings us up against a second and this time, I think, decisive consideration, at least if we may take it that the basic clauses of our semantic theory are to assign reference and satisfaction conditions in ways which are *presumed to correspond to the conceptual repertoire of speakers of the language in question*. For even if the schemes considered turn out not to enjoin any avoidable degree of complication in comparison with the favored scheme, the fact is that the range of concepts necessary in order to formulate their various clauses in each case includes, but is not included in, the simple range of concepts of observable spatio-temporal continuants and their observable properties which the favored scheme deploys. So much is obvious in the case of the schemes deploying the concept of the universal rabbithood, and the rabbit-fusion: these are ideas which you do not grasp until you know respectively what qualifies something to be an instance of the universal, and what qualifies it to be a basic part of the fusion. The same point emerges in the clause to which we had the undetached-parts theorist resort for "thewi," and indeed in the various clauses we considered that the temporal-stage theorist might propose.[17]

It is simplicity not in *semantic* theory but in the associated *psychological* theory that is at stake here. Let it be unresolved whether Quine's alternative schemes must issue in semantically more complex theories; it is certain nonetheless that their implied accompaniment must be additional psychological complexity. The effect is that their situation is therefore doubly unhappy. Not merely do they involve the ascription of superfluous conceptual resources to speakers – resources strictly unnecessary to explain their linguistic performance – but, worse, we have to regard the resources in question as lurking behind, but *inexpressible* in, the actual vocabulary of the natives' language. To have the concept of an undetached rabbit part, you need a concept of the integrated individual of which such parts are parts; to have the concept of a temporal stage of a rabbit, you need to grasp the idea of the spatio-temporal continuant of which such a stage is a stage. Yet the Quinean translation schemes will represent you as talking only of undetached parts, or temporal stages; reference to the *integrated, spatio-temporally persisting rabbit* will elude you so long as your expressive resources are fully captured by these translation schemes.

Such schemes, then, even if they can indeed cope with all the data which a sympathizer with Evans might imagine, and even if they can do so without losing out by canons of simplicity governing the construction of *semantic* theory, must, it seems, fall foul of a basic methodological consideration: that the conceptual repertoire which radical interpretation may permissibly ascribe to speakers should exceed what is actually expressible in their language, as so interpreted, only if its ascription to them is necessary in other ways in order to account for their linguistic competence. Perhaps an Argument from Below could be developed in such a way as to respect this constraint. But Quine's own examples do nothing to suggest how.[18]

6 The Argument from Above: Preliminary Clarifications

The Argument from Below operates at the level of sub-sentential expressions. Quine sometimes represents this point by the claim that the conclusion of the argument is not the indeterminacy of translation, properly understood, but rather the *inscrutability of terms*. What a proponent of the argument tries to do in the case of "gavagai," for example, is, as we have seen, to propose hypotheses about its syntactic category and reference in such a way that the truth-conditions – and hence assent-conditions – of contexts containing it are left invariant under compensating readjustments in the interpretation of the other expressions which they contain. Even if this is done successfully, the conclusion will still be consistent, therefore, with determinacy in the matter of what truth-conditions a radical interpreter is to assign to natives' utterances. True, it will be left indeterminate exactly what *thoughts* – individuated more finely than merely by their truth-conditions – should be regarded as expressed by particular native utterances. But the slack will extend no further than the existence of some room for maneuver within assignments whose truth-conditions are the same. It is doubtless for this reason, rather than to acknowledge any infirmity in the Argument from Below, that Quine writes:

> My *gavagai* example has figured too centrally in discussions with the indeterminacy of translation. Readers see the example as the ground of a doctrine, and hope by resolving the example to cast doubt on the doctrine. The real ground of the doctrine is very different, broader and deeper.[19]

Quine thus seems content to have most – perhaps all – of his eggs in the other basket.[20] And the contention of the Argument from Above is indeed stronger. It is precisely that unimprovable translation manuals may differ not merely in their interpretations of sub-sentential expressions, but in the truth-conditions they assign to sentences, and hence in which of the natives' utterances they will enjoin us – in conjunction with our own collateral beliefs about the world – to regard as true.

Here, though, there are a variety of possible theses of differing strength, which we shall do well to distinguish. Let 'M' range over unimprovable translation manuals – by whatever criteria – for the natives' language, and let 'S' denote a particular sentence of that language; let 'C' range over claims which identify the truth-conditions of sentences, and 'c' range over claims which, while falling short of identification, somehow constrain the identification of sentences' truth-conditions, for example, by saying what their truth-conditions are not. Let's say that S's meaning is:

(1) *strongly determinate* if and only if there is some C such that every M makes C about S
(2) *weakly determinate* if and only if there is some c such that every M makes c about S
(3) *weakly indeterminate* if and only if there is no C such that every M makes C about S
(4) *strongly indeterminate* if and only if there is no c such that every M makes c about S

Then any particular sentence S must be in one of three cases:

(A) strongly determinate
(B) weakly determinate and weakly indeterminate
(C) strongly indeterminate

and there are accordingly *seven* possibilities for the sentences, S, of any particular language:

(1) Every S is in case A.
(2) Some S are in case A, some S are in case B, and every S is in one of those two cases.
(3) Some S are in case A, some S are in case B, and some S are in case C.
(4) Some S are in case A, and some S are in case C, and every S is in one of those two cases.
(5) Every S is in case B.
(6) Some S are in case B and some S are in case C, and every S are in one of those cases.
(7) Every S is in case C.

Each of (2) through to (7) represents a possible indeterminacy thesis, of an increasingly radical order.

Now, if a "fact about meaning" is to be anything agreed on by all unimprovable manuals, then it is only (7) which entails that there are no facts about meaning whatever. This is important. I mentioned at the start the underlying physicalist spirit which drives Quine's argument, the perceived difficulty in finding anything for semantical properties to be in what is conceived of an essentially physical world. The thesis of indeterminacy of translation is meant to assuage this concern precisely by showing that semantic facts are *superstition*, and are therefore owed no refuge in the austere ontology of developed physical science. This radical solution will be frustrated should it turn out that Quine's arguments at best support something less thoroughgoing than a thesis of form (7). For in any other situation, there will *be* residual "facts about meaning"; maybe nothing like the rich variety of such facts that

an opponent of Quine would intuitively wish to recognize, but facts about meaning all the same. So we should have the worst of both worlds: insufficient semantic facts to do justice to our intuitions of distinctions of meaning, but enough to set up the perceived difficulty for Quine's physicalism.[21]

The taxonomy invites review of a number of issues. First, on determinacy of truth-value. It might be supposed that, whatever form of indeterminacy thesis is maintained, the effect will be to introduce a species of relativity: the truth-value of a sentence whose meaning is absolutely indeterminate will have to be thought of as likewise non-absolute, as relative to whatever the (unimprovable) manual we happen to favor assigns to it as its truth-condition. But actually there is cause for doubt about the stability of this line of thought. For the truth-value of S can be conceived as determinate relative to some particular manual only if it is thought to be determinate *what that manual has to say* about the meaning of S. And the contents of claims in translation manuals ought, by the Quinean, to be regarded as no more determinate than any others.

If relativism is accordingly eschewed, then it seems it must be conceded that any sentence in category C – any strongly indeterminate sentence – must simply be indeterminate in truth-value, at least so long as we continue to conceive of truth-value as a function of truth-conditions. But how about sentences in category B – weakly determinate but weakly indeterminate sentences? Unimprovable manuals will not converge on the assignment of any particular truth-condition to such a sentence. But they will converge in making certain claims which constrain its meaning, in particular claims which rule out certain such assignments. So the possibility is open, at least while the discussion moves at this level of generality, that such a sentence might yet be determinate in truth-value, since it might be that the space of permissible assignments of truth-conditions is sufficiently narrow to ensure that, as matters happen to stand, the sentence will be true no matter which of those assignments is made. It would all depend how far the weak determinacy extended; how many and what strength of meaning-constraining claims about S the unimprovable manuals would converge upon.

A second issue concerns the respective implications of the various possible strengths of indeterminacy thesis for the viability of ordinary intentional psychology. Assume that it is by the interpretation of what they are prepared to assent to that we are to identify by far the greater proportion of the natives' beliefs. Sentences in category C are obviously useless for this purpose. But might at least some measure of propositional-attitude psychology be feasible if our data concerns acceptances and rejections of sentences in category B? In that event we should know insufficient to determine the truth-conditions of the beliefs thereby evinced. But it is not inconceivable that the range of permissible assignments and truth-conditions on which the best manuals converged might be sufficiently restricted to ensure that, at least in certain special circumstances, the only beliefs which we could regard a particular utterance as expressing would all equally well serve the purpose of rationalizing an associated item of behavior when conjoined with certain plausibly ascribed desires. (For instance, the belief that a certain fruit was nutritious and the belief that it was merely tasty might rationalize many of the same behavioral episodes.) Again, it will all depend on how weak is the weak determinacy involved.

However, I shall not pursue these matters further. The crucial question is: Which of the various possibilities, from (2) to (7), are in the range of Quine's Argument from Above? Here is his own classic statement of the argument:

> Now my point about physical theory is that physical theory is underdetermined even by all … possible observations.… Physical theories can be at odds with each other and yet compatible

> with all possible data even in the broadest sense. In a word they can be logically incompatible and empirically equivalent. This is a point on which I expect wide agreement, if only because the observational criteria of theoretical terms are commonly so flexible and fragmentary. People who agree on this general point need not agree as to how much physical theory is empirically unfixed in this strong sense; some will acknowledge such slack only in the highest and most speculative reaches of physical theory, while others see it as extending even to commonsense traits of macroscopic bodies.
>
> Now let's turn to the radical translation of a radically foreign physicist's theory. As always in radical translation, the starting point is the equating of observation sentences of the two languages by an inductive equating of stimulus meanings. In order afterward to construe the foreigner's theoretical sentences we have to project analytical hypotheses, whose ultimate justification is substantially just that the implied observation sentences match up. But now the same old empirical slack, the old indeterminacy between physical theories, recurs in second intension. Insofar as the truth of physical theory is underdetermined by observables, the translation of the foreigner's physical theory is underdetermined by translation of his observation sentences. If our physical theory can vary though all possible observations be fixed, then our translation of his physical theory can vary though our translations of all possible observation reports on his part be fixed. Our translation of his observation sentences no more fixes our translation of his physical theory than our own possible observations fix our own physical theory.
>
> The indeterminacy of translation is not just an instance of the empirically underdetermined character of physics. The point is not just that linguistics, being a part of behavioral science and hence ultimately of physics, shares the empirically underdetermined character of physics. On the contrary, the indeterminacy of translation is additional. Where physical theories A and B are both compatible with all possible data, we might adopt A for ourselves and still remain free to translate the foreigner either as believing A or as believing B (Quine, 1970, pp. 179–180).

What exactly is the structure of this reasoning? Its premise is clearly indicated. It is the Underdetermination Thesis: the thesis, roughly, that all possible observations – all the observations that scientific observers, however idealized, wherever and whenever situated, might gather between them – do not constrain the selection of an explanatory empirical theory to within uniqueness. Alternative, incompatible theoretical accounts are always possible of any data pool, even if of infinite extent. This is the point on which Quine expects "wide agreement," although he earlier envisages possible disagreement about the level at which Underdetermination operates, some accepting that it holds only for the highest reaches of empirical theory, while others possibly allowing that it go for all empirical theorizing, *tout court*. But how exactly is the transition supposed to be effected to the conclusion: the indeterminacy of translation, and of meaning?

Quine, as the reader will have noted, explicitly disavows that it is simply a matter of applying the Underdetermination Thesis to the special case of empirical linguistics: the indeterminacy is to be "additional." But it is a good question why or whether it would matter much if the argument were indeed that direct. No doubt the direct argument would have to confront a very obvious question: Why is its legitimate conclusion not merely that theories of meaning are, like all empirical theories, *underdetermined* by the behavioral data? Why the additionally strong conclusion concerning *indeterminacy*? Quine shows no inclination to draw the conclusion that empirical theory as a whole is indeterminate. So what, for a proponent of the direct route, would distinguish empirical theories of *meaning*, making the indeterministic conclusion appropriate in their case? It may be doubted that such a philosopher could have any better

answer than to charge that to hold to the opposed view – that meanings may, in cases of indeterminacy of translation, simply lie beyond the reach of empirical detection – is to succumb to the myth of the museum (Quine, 1969, pp. 27ff.). It is to succumb, that is, to the illusion that, in a world apt for complete description by physical theory, there can possibly be states of affairs apt to confer truth and falsity on claims about meaning other than those constituted in behavioral propensities of language use which, by hypothesis, underdetermine the selection of semantic theory. But the salient point is, then, that this – the repudiation of the myth of the museum – is a point on which Quine is going to have to rely *in any case*, even if the argument follows a subtler path than the one disavowed. The immediate conclusion, whatever exactly the configuration of the subtler route to it, is still only going to be that respect for all possible data will leave the translation of the natives' utterances underdetermined. One wonders, then, what exactly the additional subtlety, whatever exactly it may prove to consist in, really has to contribute. Does it somehow make for a stronger conclusion, a more pervasive or deeper kind of indeterminacy? Or does Quine see some difficulty for the simple, direct argument which the subtler route can finesse? What does "additional" mean?

Whatever the answers to those questions, it's notable that the scope of the argument can in any case extend no further than that of the Underdetermination Thesis which fuels it. Someone who allows, for example, that only very high-level physical theory is subject to underdetermination will be under no pressure to concede indeterminacy of translation except for vocabulary which occurs exclusively in such theory.[22] And even for sentences containing such vocabulary, it will be *weak* indeterminacy, not strong, that will be suggested. For however exactly the argument is supposed to run, just as not any old interpretation of that vocabulary would result in a theory which was adequate to the relevant data, so not any old interpretation results in a translation which may justifiably be regarded as reflecting the putatively perfectly rational native scientists' beliefs. The translation of theoretical terms in the native scientists' language can be no more indeterminate than is the selection of an empirically adequate theory of those data.

Strikingly, therefore, Quine's argument promises at best the *mildest* kind of indeterminacy thesis, one of type (2) in the above taxonomy, according to which a thesis of *weak* determinacy/indeterminacy is made out merely for *some* statements. And indeed, even if the Underdetermination Thesis is extended to all empirical theorizing, the most that is in prospect is a thesis of the indeterminacy of theoretical vocabulary relative to some fixed translation of the 'observation sentences.' The argument will have nothing to say about the determinacy of the meanings of the latter; and about the interpretation of theoretical terms, it will suggest only some degree, and by no means an unrestricted one, of latitude.

7 The Argument from Above: Appraisal

Enough of preliminaries. Let us now try to map the course of the purportedly subtler route which Quine officially conceives the argument to follow. It would seem to involve reliance on the following transitional principle:

> If all possible empirical observation underdetermines the choice between theories T1 and T2 (that is, if T1 and T2 are *empirically equivalent*), then a native scientist's responses to his observations will underdetermine the choice between the ascription to him of acceptance of T1 and the ascription to him of acceptance T2.

And that may seem plausible enough. But notice that it does not, by itself, enjoin any conclusions about indeterminacy of translation. It is one thing to suppose that a rational native scientist could quite consistently hold either of two conflicting theories while respecting all possible relevant data. It is another, quite different thing to hold that the sentences by which he expresses whatever theory he does hold may, by an interpreter who respects all relevant data, be translated in different, incompatible ways. The second will follow directly from the first only if the *only* data that the interpreter has to respect concern which data – which observations – the native scientist will have set himself to respect. And that isn't plausible at all, and goes quite unsupported in Quine's presentation. For the project of translation is constrained not just by the need to identify a set of beliefs which, if rational, the native will have arrived at, but to an even greater degree by the need to find plausible *vehicles* of those beliefs in his overt linguistic behavior. Quine's picture of the situation would seem to be that all we – the interpreters – can have to go on in the end is the native scientist's acceptance of certain observation sentences. Quine generously concedes our translation of these, and allows us the assumption that the native is a fully rational theorist of the range of data which they express, so that, to over-simplify rather absurdly, if just two incommensurable but unimprovable theories are possible of these data, then the native is likely to have alighted upon one of these theories in particular. But Quine seems to be depending on the idea that there can be nothing to provide us with *further* guidance in translating the relevant parts of the native's language, nothing additional to motivate viewing it as expressive of that theory rather than of its competitor. And that seems quite unjustified. As theorists of meaning, we will have to locate a *syntax* in those parts of the native's language, and then do a plausible job of mapping the ingredient concepts of one of the theories or the other on to components of his language identified by that syntax, the mapping to culminate in a satisfactory recursive theory of meaning. Quine gives absolutely no reason to discount the thought that the case for one of the interpretations in particular may simply evaporate as soon as this serious work of interpretation gets under way. Bluntly, it may just prove impossible to find the right kind of phonological or morphological structures in the native's theoretical sentences to subserve the necessary lexicography and semantic mapping.

That is one misgiving. We encounter another when we turn to consider just what status the premise – the Underdetermination Thesis – enjoys. Quine wrote that he expected "wide agreement" on this. And, surely, is it not just obvious that theories incorporate more content than the sum of their observational consequences?[23] So isn't it perfectly intuitive that this body of consequences must be theoretically axiomatizable in a variety of inequivalent ways?

When Quine anticipated little resistance to underdetermination, no doubt that was one kind of thought he was having. For instance, let T be some empirical theory and consider two consistent but mutually incompatible supplementations of it, T1 and T2, neither of which entails any empirically testable consequences over and above those of T. Then the choice between T1 and T2 is clearly underdetermined by all possible observations. It merits emphasis, therefore, that this kind of case is *not at all to the purpose*. If Quine's argument is to work then the relevant kind of case has to be one in which, precisely because all possible observations underdetermine the choice between two theories, there is nothing to motivate the ascription to the, by hypothesis, *fully rational* native scientist of one set of theoretical beliefs rather than the other. But equally, of course, if the argument is to work it is essential that the interpreter can have no good reason to suppose that the native scientist accepts

neither theory – essential that there is not a better theory dominating both. And in the envisaged kind of case there will be: for if the native scientist is perfectly rational, he won't be inclined to accept any empirical theory the observational support for which extends no further than for a straightforwardly extricated, otherwise decent enough sub-theory: in the example as envisaged, precisely the theory T.

In brief, gerrymandered examples of Underdetermination, where the incompatibility between empirically equivalent theories is sustained only by their containing empirically idle hypotheses, won't drive Quine's argument. What the argument needs, rather, are cases where empirically equivalent but incompatible theories would either cease to be empirically equivalent, or would lose empirical content, if either was somehow truncated just far enough to eliminate the incompatibility. The clash, in other words, at the theoretical level must be owing to components which are *integral* to the theories' respective capacities to predict and explain the relevant range of observational phenomena. It is not an objection to this point that even when it is required that the axioms be finite in number, any given theory is likely to admit of a variety of axiomatizations, and that difficulties are consequently to be expected for any attempt to characterize precisely which of a theory's components should be reckoned integral to it. Since, as we have just noted, the Argument from Above won't run if the Underdetermination Thesis is made incontestable only by its trivialization, the obligation is actually on the *Quinean* to make out what is involved in the non-trivial case. Whatever it may or may not be possible to say by way of further explanation, what the Quinean requires are examples of pairs of unimprovable theories, the acceptance of each of which in its entirety would be justified on the part of one who knew of sufficiently many of its empirical successes but had no inkling of the other.

With this admittedly vague proviso, what exactly is the Underdetermination Thesis? Again, there are a number of claims of differing strengths to consider. Say that an empirical theory is *tight* just in case it is free of empirical slack of the kind just gestured at, so that it is the underdetermination of tight theories by all possible empirical data that is the material contention for Quine's argument. Let 'S' range over statements whose content potentially befits them to participate in tight theory construction, and let 'T,' 'T*' range over empirically acceptable, global such theories. Then the following are among the possibilities worth singling out:

(1)	$(\forall T)(\forall S)(S \in T \rightarrow (\exists T^*) \sim (S \in T^*))$	*Total theoretical underdetermination*: every component of any acceptable, tight global theory is omitted by another acceptable, tight global theory.
(2)	$(\forall T)(\exists S)(S \in T \,\&\, (\exists T^*) \sim (S \in T^*))$	*Partial underdetermination of any theory*: any acceptable, tight global theory will have some theoretical components which are omitted by another such theory.
(3)	$(\exists S)(\forall T)(S \in T)$	*Partial determination of all theories*: some theoretical statements feature in any acceptable, tight global theory.
(4)	$(\forall T)(\forall S)(S \in T \rightarrow (\forall T^*)(S \in T^*))$	*Total determination of empirical theory*: the theoretical components of any acceptable, tight global theory feature in all such theories.

Now, allowing that the last may be merely utopian, about which (if either) of the first two of these can "wide agreement" be expected? Well, perhaps the history of science throws up some support for an Underdetermination Thesis of type (2). It is possible, for instance, though this is a matter for experts, that Special Relativity Theory and the Lorentzian Theory of Corresponding States share all their testable consequences, and that either might thus in principle be incorporated within an acceptable, tight global theory.[24] If so, then – since no acceptable, tight global theory will contain each of these as sub-theories, but must contain some theory of the phenomena which they explain – thesis (2) may be true. But such local examples seem special at best. It is hard to foresee what argument there might be for something stronger than an Underdetermination Thesis of type (2). Thesis (1), let us be clear, asserts that it is in the nature of empirical theory construction that any tight, empirically adequate, global theory will contain *only* dispensable theoretical claims. What reason is there to think that this is so?

For our present purposes, the crucial reflection is that thesis (3) – that such theories will agree on a common core of theoretical claims – is consistent with thesis (2). So unless the Quinean can make thesis (1) stick, the premise of the Argument from Above, whatever its exact detail, is going to be consistent with the idea that an ideally rational native theorist will be bound, if he is able to take account of sufficiently much of the available data, to arrive at certain *specific* theoretical beliefs, just in virtue of the nature of the project in which he is engaged. And if that were so then, unless there is some special reason to worry about the identifiability of such beliefs, we may equip ourselves, as hypothetically ideal interpreters, with a knowledge of what they are. So equipped, our attempt to interpret the native scientist will be subject to an additional constraint: that of locating expressions for these privileged beliefs among the theoretical sentences which the native scientist is prepared to accept. This constraint may then motivate assumptions about the syntax and meanings of sub-sentential expressions in the native's theoretical language which may rub off on the translation of sentences expressing beliefs of other kinds. In short, it may be an additional source of determinacy of translation.

Those suppositions may, to be sure, be utterly fanciful. The point is only that the Underdetermination Thesis, if it is anything less than the radical thesis (1), is going to be *consistent* with them, and hence cannot validly enjoin any conclusion about indeterminacy of translation in the kind of way Quine seems to have had in mind. Quine's thought, in essentials, was that an assumed knowledge of the meanings of the natives' observation sentences could no more narrowly constrain the interpretation of their theoretical language than the totality of true observations which they could express in that vocabulary would constrain their selection of an empirical theory. We have already had cause for misgivings about the refusal, implicit in this comparison, to acknowledge the routine syntactic constraints to which radical interpretation is subject. But now it appears that Quine has in any case to rely upon what is, so far as I am aware, a quite unsupported and implausible version of the Underdetermination Thesis. To wit, only thesis (1) will do. For once theory construction is allowed to be partially determinate – thesis (3) – ideal interpreters will be constrained to find, among the sentences which a putatively rational native scientist is prepared to accept, some which serve to express the privileged core of empirically determined theoretical beliefs. It cannot be excluded – at least, not without further argument, yet to be provided – that this constraint would greatly reduce their freedom of interpretation, or even that it would have the effect that the interpretational project is uniquely determined. (Maybe each item of the native's theoretical vocabulary occurs in the privileged core.)

Again, I'm not suggesting optimism about such possibilities. It is merely that the premise for the Argument from Above, to the extent that it is something for which support might be forthcoming from the history of science, is consistent with them, and hence insufficient for Quine's notorious conclusion.

* * *

We have found each of Quine's classic arguments, from Above and Below, to provide less than compelling grounds for either the thesis of the indeterminacy of translation or even, more modestly, for that of the inscrutability of terms.[25] Moreover, as stressed at the beginning, Quine's own views have been modified and, in certain respects, softened since he first formulated the arguments on which we have concentrated. Nevertheless, a conviction of the resistability of those original lines of thought is no cause for complacency on the part of friends of the intensional. Although the thesis has been usually received as a paradox, it should be remembered that, within a broader physicalist framework, the indeterminacy of translation would come, at least at first blush, as a relief – the obviation of any need to locate meanings, and intentional states, within a purely physical world. As it is, an abiding tension between the thoughts on the one hand that *in some sense* the world is exhaustively physical and, on the other, that ordinary talk of meanings and the propositional attitudes ought to be unproblematical, remains, and its reconciliation continues to be one of the great issues facing contemporary philosophy.[26]

Notes

1 The reader should be reminded, however, that while this general concern has undoubtedly conditioned and intensified the reaction to the 'skeptical argument' which forms the core of Kripke's interpretation of Wittgenstein, that argument itself – in contrast to Quine's – makes no explicit behaviorist or physicalist assumption.

2 In fact they are directed at different versions of it, as we shall see.

3 For Quine's own original formulations, see Quine (1960, p. 27ff.).

4 Large and subtle issues are raised here. At first blush, it may seem obvious that there are first-/third-person asymmetries of this kind; for instance that, even if my linguistic behavior does underdetermine the translation of my uses of the word "rabbit" – to anticipate Quine's famous example – leaving the radical interpreter with no clearly superior choice among a range of rival interpretations of them, *I* at least can be in no doubt about which, if any, of these rival interpretations is correct. For by "rabbit," I mean of course: *rabbits* – so that's the right interpretation, and anything else is incorrect! But of course the interpreter will expect me to say that. The question, for him, is exactly what knowledge I thereby express. And the question for me – since I would indeed affirm that sentence whatever I meant by "rabbit" – is whether I thereby express any *substantial* piece of knowledge denied to the radical interpreter.

5 Here is a well-known formulation of that scorn:

> One may accept the Brentano thesis [of the irreducibility of intentional idiom] either as showing … the importance of an autonomous science of intention, or as showing the baselessness of intentional idioms and the emptiness of a science of intention. My attitude … is the second…. If we are limning the true and ultimate structure of reality, the canonical scheme for us is the austere scheme that knows … no propositional attitudes but only the physical constitution and behavior of organisms. (Quine, 1960, p. 221)

6 Perhaps because it has not been properly appreciated how deep it goes. Someone might think that, so far from posing a problem for Quine, the upshot here – the indeterminacy of truth-value of individual sentences – is merely part and parcel of Quinean holism: the idea, elaborated in §§5 and 6 of "Two dogmas of empiricism," in *From a Logical Point of View* (Quine, 1953), that individual sentences indeed have no meaning except in the context of a larger system – that "the unit of meaning is the whole of empirical science." Indeterminacy of truth-value at the level of sentences may not seem too shocking a matter if it is theories as a whole, rather than their ingredient statements, that are properly conceived as the bearers of truth and falsity.

This suggestion just invites the question, however, of why the whole dialectic does not then replay itself at the level of theories. After all, isn't a theory just a big sentence? So isn't the effect of the holism just to caution against thinking of *small* sentences as the bearers of determinate truth-values? Whereas the problem is to recover, once meaning is indeterminate, *any* space for determinacy of truth-value, even for sentences as big as a global physical theory. If, in company with the indeterminacy of meaning, there is nevertheless to be such a thing as determinate truth-value at any level, then Quine officially needs, for items at that level, an account of truth, and of what determines truth, that liberates the notion from dependence upon any semantic parameter.

7 The Above/Below terminology is Quine's own (1970, p. 183).

8 At least in Quine (1970).

9 The reader may care to think through how the point might apply for **Φ** = "… is the same as…" and F = "rabbit" and G = "temporal stage of a rabbit."

10 Evans seems not to have had a problem with the idea that something might be simultaneously both white and bloodstained! A reader who does will be able to construct another example to make the points about to be illustrated.

11 There will be questions, of course, about its scope where it occurs in the latter mode in sentences involving compound predication; the reader may care to think through what patterns of assent and dissent might motivate particular interpretative proposals about the scope conventions in play in the natives' language.

12 It's straightforward to envisage the sort of data that might prompt the suggestion. Suppose, in full view of a group of native speakers, we take a deeply and thoroughly bloodstained rabbit and wash it completely clean in a stream. Then we put to them each of the following sentences for assent or dissent:

odolby neg gavagai	odolby gavagai
odolbyp gavagai	odolbyp neg gavagai

Finding that the natives assent to both sentences on the left, and dissent from each on the right, would confirm the interpretation of the "-p" suffix as a past-tense indicator. We may suppose this pattern exemplified across a wide range of cases.

13 In order most easily to illustrate Evans's treatment within the framework of the discussion so far, I shall use "odolby" sometimes as present tensed and sometimes as a tenseless counterpart.

14 I am prescinding from the awkwardness, for Evans's purposes, that his objection only engages if the stage-theorist has somehow been stuck with the assumption that the reference of the particular use of "gavagai" is to the last stage in the life of the rabbit in question (i.e., not to an earlier bloodstained stage of that rabbit, or to a stage of a different rabbit). An analogue of that assumption might be more secure if we were concerned with a different example: one whose featured predicate was true only of the last stage in the life of a particular, recently salient rabbit, and of no stage of any other rabbit in the recent experience of our interlocutors. (Evans actually has "running," but that presents the same awkwardness.)

15 This reading is mandated by the reflection that to treat the clauses as concerning *type predicates* instead would rapidly lead to contradictions. Let y be bloodstained at t_1 but not at t_2, and let x be a stage of y. Then $\langle x,t_1 \rangle$ satisfy "odolby" (tenseless), since there is a y such that y is bloodstained at t_1 and x is a stage of y. Let t_u first be t_1. *Then x satisfies "odolby" (present tensed)*. Note that this

upshot involves no relativization to the time of utterance. So now let t_u be t_2. There is no y such that y is bloodstained at t_2 and x is a stage of y. *So x does not satisfy "odolby" (present-tensed).* The italicized claims are overtly contradictory; however, the contradiction is merely apparent if we take it that the two occurrences of "odolby" refer to different tokens of the same type.

Could this contradiction have constituted Evans's objection? No, since it is elicited with respect to a single stage, x, and makes nothing of the generalization across stages on which he remarks. In any case it is easily resolved, as we have just seen, without recourse to anything like his second proposal.

An alternative way to avoid the contradiction for an interpreter who for whatever reason wanted his semantic clauses to concern type-predicates rather than tokens, would be to relativize the notion of satisfaction to times. Such a proposal might proceed with clauses along the following lines (which also avoid recourse to tenseless object-language predicates):

(1) x satisfies "odolby" at time t if and only if something is bloodstained at t of which x is a temporal stage.
(2) x satisfies "odolbyp" at time t if and only if there is some time t′, earlier than t, such that x satisfies "odolby" at t′.

And so on. Note that stage-promiscuity would still be a consequence: such a treatment will entail that if any stage satisfies a predicate at a time, then all stages of the same continuant will satisfy that predicate at that time.

16 Another misgeneralization would confuse stage-promiscuity with a kind of *predicate-promiscuity* – the idea that any stage which satisfies a tensed predicate simultaneously satisfies all other tenses of the same predicate. Predicate-promiscuity would likewise be at odds with the natives' selective use of tensed predicates and, as the reader may care to verify, is indeed entailed, via stage-promiscuity, by Evans's first kind of clauses if they are taken to concern type-predicates. But there is no such implication once those clauses are taken to concern tokens – or are replaced by clauses in which satisfaction is relativized to time (cf. note 14).

17 The development of this point for the case of the feature-placing interpretation is left as an exercise for the reader.

18 This point is also important for the significance of Putnam's permutation argument in his *Reason, Truth and History* (1981, pp. 32ff.); for discussion, see Chapter 27, PUTNAM'S MODEL-THEORETIC ARGUMENT AGAINST METAPHYSICAL REALISM.

19 Quine (1970) opening paragraph. The limitation of the Argument from Below to the inscrutability of terms is expressly recognized at p. 182 of the same paper.

20 Though the reader should note the gist of the concluding remarks to Quine (1970).

21 It is true, of course, that distinctions of meaning which survive Quine's argument will be ones which can be behaviorally grounded and are thus properly public. But that is not enough to make them hygienic from the physicalist point of view. As I stressed at the beginning, the basic worry for physicalism concerning the semantic is its *normativity*, and public meanings are no less normative for being public. A Quinean argument which, while not actually exploiting the presumed normativity of meanings, somehow or other did away with all semantic facts would save the physicalist the task of accommodating this particular province of normativity; but if a residue of semantic facts remains, then so does the problem.

22 Robert Kirk attempts to construct a counter-example to the Argument from Above, exploiting this point: cf. Kirk (1973, p. 198ff.).

23 Strictly, of course, empirical theories issue in categorical claims about observational phenomena only when supplemented with observational premises – statements of "initial conditions." The (intentionally) rhetorical question can be preserved by thinking of the observational consequences of a theory as the corresponding conditional statements, whose antecedents specify the initial conditions, and whose consequents encode the theory's prediction for those circumstances.

24 For detailed discussion of this example, see Zahar (1973, pp. 95–123, 233–262).

25 Always provided, that is, that the issue concerning the latter is not taken to be settled just by the possibility that the assignments of sub-sentential reference effected by an empirically adequate semantic theory for a given language may be varied without loss of empirical adequacy – that is, without loss of consistency with observed patterns of assent. If that possibility is all that is at issue, then the matter is, arguably, settled in Quine's favor by a generalization of the sort of permutation argument offered by Putnam: see Chapter 27, PUTNAM'S MODEL-THEORETIC ARGUMENT AGAINST METAPHYSICAL REALISM. But we have observed that semantic theory has to answer to much more than empirical adequacy in that limited sense.

26 Thanks to Bob Hale, Christopher Hookway, Gabriel Segal, and Jason Stanley for very helpful comments.

Postscript

ALEXANDER MILLER

In this brief postscript, I'll argue that Quine's arguments for the indeterminacy of translation survive the objections developed by Crispin Wright in his original (rich and stimulating) entry in the first edition.

1 The Argument from Below I: Simplicity in Semantic Theory

Wright attempts to develop a general argument that will undermine Hookway-style defenses of Quine in the face of the considerations adduced in Evans (1975): that is, defenses of Quine that proceed by assigning "a variety of syntactic roles, and/or semantic ambiguities, to the expression in question" (p. 683).[1] Wright's argument turns on the idea that when empirical theories concern some robustly factual subject-matter, the fact that one empirically adequate theory is simpler than another doesn't entail that it is the simpler of the two theories that captures the facts: on the idea, in other words, that where a robustly factual subject-matter is concerned, simplicity is not a truth-conducive virtue.[2] Given this, and given that Quine's attack on the "myth of the semantic museum" undermines the idea that semantics is robustly factual, the mere complexity of the Hookway-style translation schemes

relative to the simplicity of their Evans-style competitors entails that the latter are true, thus undercutting Quine's argument "from below."

Quine can certainly grant the conditional

(I) If theories concern a robustly factual subject-matter, simplicity is not a truth-conducive virtue.

However, he can question whether Wright is entitled to the desired conclusion

(III) Simplicity is a truth-conducive virtue for theories of meaning.

Attempting to reach (III) on the basis of (I) and

(II) Theories of meaning do not deal with a robustly factual subject-matter

would commit the fallacy of denying the antecedent. In order to reach (III) validly Wright requires

(IV) If theories do not deal with a robustly factual subject-matter, then simplicity is a truth-conducive virtue.

Quine, however, can reject (IV) by arguing as follows. It may well be the case that if a theory deals with some *minimally factual* subject-matter, simplicity can be regarded as a truth-conducive virtue for that theory. However, being minimally factual is only one way a theory can fail to deal with a robustly factual subject-matter: it can also fail to do so by failing to deal with a factual subject-matter *tout court*. Clearly, for such theories, *no* theoretical virtues are truth-conducive.

Wright could perhaps retreat to

(V) If theories deal with a minimally factual subject-matter, simplicity is a truth-conducive virtue

and attempt to reach (III) via the application to semantic discourse of a "disciplined syntacticist" conception of truth-aptitude of the sort he favors: since "'gavagai' means *rabbit*" and the like can be negated, embedded in conditionals, and so on, and are subject to acknowledged standards of correct use, they can be regarded as dealing with a minimally factual subject-matter (Wright, 1992, chs 1 and 2). This suggestion, though, would seem to depend on assumptions about the determinacy of rules (whether syntactic rules or rules concerning "proper use") whose deployment in this context would beg the question against Quine. Arguably, then, Wright's first rejoinder to Hookway's defense of Quine misses its target.[3]

2 The Argument from Below II: Simplicity in Psychological Theory

Wright has another anti-Quinean argument, this time turning on considerations of simplicity in the psychological theory implied by a given theory of meaning:

> [T]he conceptual repertoire which radical interpretation may permissibly ascribe to speakers should exceed what is actually expressible in their language only if its ascription to them is necessary in other ways in order to account for their linguistic competence. (p. 684)

Call this "Wright's Principle." The Quinean translation manual that takes the native to mean *undetached rabbit part* by "gavagai" will ascribe to the native grasp of the concept of an undetached rabbit part and thereby grasp of the concept "of the integrated individual of which such parts are parts" (p. 684). In other words, since grasp of the concept of an undetached rabbit part implies grasp of a concept (*rabbit*) whose instances are integrated, individual rabbits, the Quinean translation manual involves ascribing grasp of the latter to the native, and – crucially, according to Wright – the native will have no way of expressing this concept linguistically given the resources at his disposal. Wright's Principle would thus be violated.

Clearly, there would be no clash with Wright's Principle if the ascription of the concept *rabbit* was in fact necessary to explain some aspect of the native's linguistic competence. So what if the Quinean suggests that grasp of the concept *rabbit* is necessary to account for the native's competence with "gavagai" *as interpreted by the Quinean translation manual*? Wright would presumably reply that what is required is some *independent* justification for ascribing grasp of the concept *rabbit*: that is, some aspect of the native's competence that does not itself presuppose the correctness of the Quinean translation scheme. Equivalently, citing competence with "gavagai" as interpreted in the Quinean manual as the relevant aspect to be explained would be disallowed on the grounds that it is *ad hoc*.

However, disallowing this suggestion on the grounds that it is *ad hoc* is of a piece with the idea that simplicity is a truth-conducive virtue for theories of meaning: the envisaged maneuver is ruled out for introducing complexity into the characterization of the native's competence that is not warranted by some other aspect of his linguistic behavior. However, as argued in §1 of this postscript, it is not clear that Wright is non-question-beggingly entitled in this context to the idea that simplicity is a truth-conducive virtue for theories of meaning.

In any event, even putting that line of argument to one side, it can be argued that the native can in fact express his grasp of the concept *rabbit* via existing linguistic resources. To be sure, "gavagai" on its own won't turn the trick, but "gavagai" *in combination with other expressions in the native's linguistic armory* may well provide the necessary means: for example, "an integrated individual of the kind that gavagai are undetached parts of" refers to integrated, individual instances of the concept *rabbit*. Squaring the Quinean interpretation of "gavagai" with suitable interpretations of the other constituents of this expression in a way that reflects the relevant facts about stimulus meaning may turn out to be non-trivial, but Wright himself (p. 682–683) counsels against the assumption that there will always be some point at which the Quinean will be unable to make the necessary kind of reinterpretative adjustment.

Arguably, then, neither of Wright's arguments – at the semantic level or the psychological level – convincingly block Quine's argument from below.

3 The Argument from Above I: The Underdetermination Thesis

Wright raises a worry about the formulation of one of Quine's key premises, namely, that physical theory is underdetermined by all possible observational evidence. Quine writes:

> Theory can still vary though all possible observations be fixed. Physical theories can be at odds with each other and yet compatible with all possible data even in the broadest sense. In a word they can be logically incompatible and empirically equivalent (1970, p. 179).

Wright argues that the Underdetermination Thesis requires a tighter formulation than Quine provides for, and then that this tighter formulation leaves scope for constraints, not envisaged by Quine, the satisfaction of which narrows down the scope for indeterminacy of translation. In this section I'll discuss the first of these arguments, before turning to the second argument in §4.

Suppose that a fully rational scientist accepts an empirical theory T and that T1 and T2 are two mutually incompatible extensions of T containing no empirically testable consequences beyond those implied by T. Wright concedes that the choice between T1 and T2 is underdetermined by all possible observations, but argues "that this kind of case is not at all to the purpose" (p. 689). According to Quine, a fully rational scientist can choose T1 over T2, or choose T2 over T1, but Wright argues that he must also rule out the possibility that the fully rational scientist accepts *neither* T1 nor T2. And in the relevant kind of case, Wright argues, Quine will not be in a position to do this: the fully rational scientist "won't be inclined to accept any empirical theory the observational support for which extends no further than for a straightforwardly extricated, otherwise decent enough sub-theory: [for example], precisely the theory T" (p. 690).

In response to this, we can argue that choosing T1 or T2 over T needn't mark a departure from full rationality on the part of the native scientist. Suppose that the derivation of observational consequences from T1 utilizes theoretical resources that could be dispensed with at no empirical cost, allowing the derivation of the same consequences from the leaner sub-theory T in a quicker, more efficient manner. Would a fully rational scientist necessarily be averse to T1? It's not clear that he would be. To be sure, if his time is at a premium then it would be irrational for him to rely on T1 rather than T. However, suppose he has time to spare – perhaps even looking for a way to pass the time while waiting for a friend at the café. Given this end, it wouldn't be irrational for him to rely on T1: if he relies on T he may find himself bored and uncomfortable prior to the arrival of his friend. Wright's objection, then, appears to depend, not only on the assumption that fully rational agents necessarily have certain ends (which would be controversial enough in itself), but also on the assumption that those ends would necessarily be frustrated by the choice of an empirical theory whose observational support extends no further than that for an otherwise acceptable sub-theory. This is by no means obvious. In the absence of detailed argument, then, Wright's case against Quine's version of the underdetermination claim appears to falter.[4]

4 The Argument from Above II: Tightness and Indeterminacy

Suppose, though, that Wright's objection to Quine's Underdetermination Thesis stands. Wright suggests that what Quine needs is a version of the Underdetermination Thesis couched in terms of "tight" empirical theories, where "tightness" is characterized as follows. Where T is an empirical theory, incompatible theories T1 and T2 are "tight" extensions of T if they both have observational consequences not implied by T and are both such that if they are "slimmed down" to the point at which they are no longer incompatible they cease to have observational consequences not implied by T. (This allows Quine to avoid the worry discussed in the previous section, since a fully rational scientist who knows T can choose T1 but not T2 or T2 but not T1 without violating any strictures on rationality, but he won't opt to choose neither T1 nor T2 because of the consequent loss of predictive power.)

Can a plausible version of the Underdetermination Thesis be formulated in terms of this notion? Wright suggests that the best Quine can hope for here is: "any acceptable, tight global theory will have some theoretical components which are omitted by another such theory" (p. 690). He then argues (i) that underdetermination – so construed – is consistent with the idea that "some theoretical statements feature in any acceptable, tight global theory" (p. 690) and (ii) that the assumptions about the syntax and meanings of the relevant sub-sentential expressions that we need to make in order to accommodate the core theoretical statements in (i) may, for all that Quine has said, induce determinacy in the translation of theoretical statements outside the core. Since the Underdetermination Thesis – so construed – does not preclude either (i) or (ii) it "cannot validly enjoin any conclusion about indeterminacy of translation in the kind of way Quine seems to have had in mind" (p. 691).

I'll argue that Wright's objection fails to damage Quine's argument, even if we concede all of his claims about what would constitute a plausible formulation of the Underdetermination Thesis.

Quine's argument contains three distinct premises. The first of these is an expression of Quine's physicalism as applied in the cases of translation and meaning:

> PHYSICALISM (PHYS): The facts about correct translation, if there are any, are constituted by the facts about stimulus meaning.

Then comes

> UNDERDETERMINATION (UND): The truth of a physical theory is undeterdetermined by observables in the sense that any acceptable, tight global theory will have theoretical components which are omitted by another such theory.

Next, the principle that translation preserves degree of empirical slack:

> TRANSLATION (TRANS): Insofar as the truth of a physical theory is underdetermined by observables, the translation of the foreigner's physical theory is underdetermined by translation of his observation sentences.

Now, UND and TRANS imply that the translation of a foreign scientist's observation sentences underdetermines the choice of a translation of this physical theory at the relevant level (i.e., the level where underdetermination kicks in).

Since – according to Quine – the meaning of an observation sentence is identical to its stimulus meaning[5] – it follows that the sum total of facts about stimulus meaning (i.e., in this context the sum total of facts *tout court*) underdetermines the choice of translation manual. Hence, there is no fact of the matter as to which translation manual captures the meaning of the foreign scientist's theory.

Quine's claim is thus that PHYS, UND, and TRANS imply the relevant version of the indeterminacy thesis (call this IND). Let CORE be the claim that "some theoretical statements feature in any acceptable, tight global theory." Wright's claim, then, is that the argument from above fails because UND is consistent with CORE and CORE is consistent with the determinacy of translation (not-IND).

This, however, fails to damage Quine's argument. Consider the following argument (where P, Q, and so on are schematic letters):

> P, $P \rightarrow Q$, $Q \rightarrow R$, therefore, R.

Is it any sort of objection to the validity of this argument that P → Q is consistent with T and that T is consistent with not-R? Clearly not. What would be damaging would be the claims that P → Q implies T and that T implies not-R. Given both of these, the set of initial premises {P, P → Q, Q → R} would be inconsistent, showing that at least one of them is false. We would then have no sound way of reaching the desired conclusion R on the basis of them. The same goes for Wright's argument against Quine. Even if we grant that UND is consistent with CORE and that CORE is consistent with not-IND, that in itself poses no worry for Quine. What would be a problem for Quine would be an argument to the effect that UND implies CORE and that CORE implies not-IND. If this were the case the argument as stated could be valid only at the expense of having at least one false premise (since the initial set of premises would imply a contradiction): in other words, its unsoundness would have been established. However, Wright himself makes it clear that he is not suggesting that UND implies CORE or that CORE implies not-IND. He says that he is not suggesting optimism about such possibilities, and indeed describes them as "utterly fanciful" (p. 691). So, for all that Wright has shown, Quine's Argument from Above survives intact.[6,7]

Notes

1 Unless otherwise specified, all references in the text are to Wright's "Indeterminacy of Translation" chapter.

2 Wright himself uses "factual" rather than "robustly factual" in this context, but the idea that what constitutes truth may be minimal in one region of discourse but robust in another is a centerpiece of the approach to realism and anti-realism developed in Wright (1992) and elsewhere, and using it here helps (I think) to see why Wright's rejoinder to Quine in this context is unconvincing.

3 A version of the argument of this section appeared in Miller (2006).

4 Wright could reply that the question about rationality we should be concerned with here is the question whether to *believe* T1 rather than T and then argue further that nothing has been done to suggest that it could be more rational to believe T1 in this case. (Thanks to Bob Hale for raising this worry). However, Quine doesn't need the claim that the fully rational scientist *must* believe T1, only that – consistent with his status as fully rational – he *may*. So isn't the onus on Wright to show that it would be *irrational* for him to believe T1 rather than T? What is the argument for this claim?

5 Observation sentences are sentences whose "stimulus meanings may without fear of contradiction be said to do full justice to their meanings"(Quine, 1960, p. 42).

6 Of course, it would be a problem for Quine if PHYS, UND, and TRANS *collectively* were consistent with not-IND. But since Wright's objection focuses on UND alone rather than on the entire set of premises employed by Quine, there appears to be nothing in what he says to substantiate the stronger, potentially more damaging consistency claim. Wright's references to syntax and the "routine syntactic constraints to which radical interpretation is subject"(pp. 689, 691) won't turn the trick, neglecting as they do the fact that empirical theories are already regarded as consisting of *syntactically structured sentences* at the point at which they fall within the purview of UND and TRANS. Wright is left with the ungrounded, question-begging assertion that the premises of Quine's argument are consistent with the determinacy of translation. (This objection to Wright echoes an objection that can be leveled at Robert Kirk's attack on the argument from above in his (1973) and (1986, ch. 6), as well as his most recent discussion of the argument from above in §10 of his (2004). See Miller (2006, pp. 105–106).

Putnam's Model-Theoretic Argument against Metaphysical Realism

BOB HALE AND CRISPIN WRIGHT

Metaphysical realism, as Hilary Putnam conceives it, is not a single, monolithic doctrine, but an amalgam of several closely associated philosophical ideas about the relations between language and reality, and between truth and knowledge or justifiable belief. One component on which Putnam places considerable emphasis is that even an ideal theory (a theory that is '*epistemically* ideal *for humans*' – ideal by the lights of the operational criteria by which we assess the merit of theories) may nevertheless be, in reality, false.[1] But commonly, Putnam presents metaphysical realism as involving adherence to three other claims, of which he takes this feature to be a consequence: that "the world consists of a fixed totality of mind-independent objects," that "there is exactly one true description of the way the world is," and that "truth involves some sort of correspondence between words or thought-signs and external things and sets of things."[2]

The so-called model-theoretic argument has played a leading role in the campaign Putnam has waged, in writings since 1976, against this outlook. Our leading questions will be: What is the argument? How is it best conceived as working? *Does* it work? §I takes up the first, and gives our reasons for concentrating, thereafter, on the version of Putnam's argument set forth in his *Reason, Truth and History* (1981). In §II we explain how, in general terms, that argument is best conceived as working. Cursory inspection of Putnam's overall dialectic reveals it to incorporate three sub-arguments, collectively designed to show that the metaphysical realist confronts an insuperable problem over explaining how our words may possess determinate reference. In our next three sections we expound these three sub-arguments in more detail, and offer some critical reflections on them. §III considers Putnam's version of the Permutation Argument, aimed at showing that reference cannot be determined by fixing the truth-conditions of whole sentences. In §IV we then review his argument that reference cannot be fixed by our intentions or anything else 'in the head'; and in §V we review his 'just more theory' argument, designed to show that the

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

metaphysical realist cannot rescue the situation by appeal to causal or other natural connections between our words and the world. Having argued that the last of these arguments fails, we consider in §VI whether Putnam's dialectical purposes might be better served by other, more specific arguments he has advanced elsewhere, aimed at showing that the project of giving a naturalistic account of reference is hopeless. In §VII we consider how the considerations adduced by Putnam might be seen as an argument telling selectively against metaphysical realism; and we conclude, in §VIII, with a brief assessment of how far Putnam's argument, so viewed, may be taken to succeed.

I

There are significant differences between the versions of Putnam's argument in "Models and reality" (1977) and in *Reason, Truth and History* (1981). Both confront the metaphysical realist with the same challenge – to show how words can stand in the determinate referential relations which his world-view demands. But the latter furnishes the more complete case for thinking the metaphysical realist incapable of meeting it. "Models and reality" deploys the Löwenheim–Skolem theorems, and closely related completeness results, to show – if all goes to plan – that no assignment of truth-values (however tightly constrained) to any (however comprehensive) class of whole sentences can suffice to fix the reference of terms and predicates. But there remain, so far as the argument of "Models and reality" goes, various ways a metaphysical realist may respond: for example, that speakers' intentions or other intentional states play an essential role; or that, if the reference of words is to be thought of as determined via their role in complete sentences, it is not those sentences' truth-*values*, but their truth-*conditions*, that matter. Further argument, of precisely the kind attempted in *Reason, Truth and History*, is needed to close off such moves.

In broadest outline, Putnam's thought in *Reason, Truth and History* has the following structure: If the world is to be conceived as consisting of "some fixed totality of mind-independent objects," with truth consisting in "some sort of correspondence relation between words or thought-signs and external things and sets of things" (Putnam, 1981, p. 49), then there must be determinate referential relations between the words and the things. But if so, the metaphysical realist owes an account of how that can be so. Putnam argues, by reviewing three, putatively exhaustive directions in which it might be sought, that there can be no such satisfactory account:

First, '*what goes on in the head*' *cannot determine what we are referring to*. We can imagine, Putnam suggests, a planet – Twin Earth – very much like Earth, populated by creatures very like ourselves, in surroundings very much like our own. There is, however, an interesting difference – the substance that fills Twin Earth streams and rivers, lakes and puddles, and comes out of Twin Earth taps, and so forth, is not H_2O but has a different chemical composition, XYZ. However, XYZ has just the same phenomenological properties as our water – it looks and tastes the same, and so on, and is, indeed, called 'water' on Twin Earth. If a Twin Earth dweller were somehow transported to Earth, she would not be able to tell our water apart from the liquid she encounters in similar circumstances back on Twin Earth. Her watery thoughts and experiences are, subjectively or 'from the inside,' just like ours. In point of *pure* mental states relevant to the use of 'water' – that is, mental states identified neutrally with respect to the existence and character of such external things as might ordinarily get mentioned in their description – Twin Earth dwellers are indistinguishable from us.

Yet when they speak of 'water,' they are referring to XYZ, whereas we are referring to H_2O. So 'what's in the head' – pure mental states – does not determine reference. Reference varies in a way that cannot be explained by appeal to pure mental states. But to appeal to *impure* – world-involving – states would be just circular.[3]

Second, sub-sentential reference cannot be determined by fixing, via 'operational and theoretical constraints,'[4] either the truth-values *or even the truth-conditions* of whole sentences. This stronger conclusion is now obtained using more modest model-theoretic resources than in "Models and reality." Given one scheme of reference which induces, at each possible world, such-and-such truth-values on complete sentences, we can obtain, by permutation, as many rival schemes as you like, which agree with the 'intended' scheme on the truth-values of whole sentences in *each* world, but diverge over assignments to terms and predicates.

Third, it is no use appealing to any further non-intentional – for example, causal – condition as the needed source of referential determinacy. Any such appeal must assume, for example, that it is at least determinate what worldly relation our word 'causes' stands for. Saying that we use 'cats' to speak of just those things that stand in such-and-such causal relations to our use of the word is 'just more theory' – and, as such, just as liable to unwanted interpretations as anything else we may say.

II

There has been a tendency for commentators to interpret this train of thought as leading to a skeptical paradox comparable to that developed by Kripke in Wittgenstein's name (see Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING, §2): as Kripke's skeptic argues that there are no facts about meaning, so 'Putnam's Paradox' would have it that there are no facts about reference, all candidates for the constitution of such facts – the truth-conditions of sentences, speakers' intentional states, and causal and other forms of natural relationships between words and the world – failing to deliver the appropriately determinate goods. It is consistent with such an interpretation of Putnam's argument that he should think, as he certainly does, that the paradox admits of resolution, much as Kripke holds that there can be a solution to *his* Wittgensteinian paradox. But then the suggested parallel begins to limp. For one thing, it enjoins, taken strictly, that any solution will leave in place its skeptical conclusion – that there are no facts about reference – just as Kripke's skeptical solution leaves in place his skeptical conclusion, that there are no facts about meaning. If this were the intended form of Putnam's message, we should expect to find him explaining why/how it is that his preferred *internal realism*[5] can accept such indeterminacy with equanimity. But that is not what he does. What we find is, rather, the claim that the internal realist has no trouble *discounting* unintended interpretations of the sort that plague metaphysical realism.[6] Moreover, while it is true that metaphysical realism requires determinacy of reference – since without it, there appears to be no making sense of the claim that an ideal theory may yet be false – it appears that an outright demonstration of indeterminacy could not tell *selectively* against metaphysical realism. For while internal realism stops short of claiming that even an ideal theory may be false, it will surely grant that a *less than ideal*, but still consistent, theory may be so. And this seems to require setting aside unintended interpretations just as much as does the metaphysical realist's more ambitious claim.

So what is the intended structure of the argument? It might be supposed that Putnam's purpose is not to explode the notion of reference altogether, but by engineering a *conditional*

explosion – by showing that some distinctively metaphysical-realist assumption subserves a proof of indeterminacy – selectively to dispossess the metaphysical realist of the notion. The fact that, as will emerge, no specifically metaphysical-realist assumption oils the wheels of any of the three sub-arguments tells against this line: How, if so, could their combination spell trouble for metaphysical realism but leave internal realism unscathed?[7]

No: the right way to receive Putnam's argument, or so we suggest, is as turning on the crucial claim that *the metaphysical realist distinctively owes an explanatory/constitutive account of reference, but cannot deliver*. Much of what Putnam writes in *Reason, Truth and History* seems to confirm that this is indeed the primarily intended line of attack. The problem about reference, to which chapter 2 in the book is devoted, is repeatedly described as the problem of accounting for *how* the reference of our terms is fixed.[8] The emphasis throughout is on the need for explanation and the metaphysical realist's inability to supply one. Putnam writes:

> Of course the externalist agrees that the extension of 'rabbit' is the set of rabbits … But he does not regard such statements as telling us what reference *is*. For him finding out what reference *is*, i.e., what the *nature* of the 'correspondence' between words and things is, is a pressing problem … For me there is little to say about what reference is within a conceptual scheme other than these tautologies.[9]

The prevailing thought, then, would seem to be that the metaphysical realist incurs certain explanatory obligations which, for the internal realist, *simply do not arise* – that the internal realist may reasonably stay silent when questions are put about the *constitution* of the reference relation, about what makes it the case that a particular expression has the reference it does.

Why this should be so is a matter to which we shall return. But this, we shall assume, is how the overall gist of the argument should be interpreted.

III

Deferring issues about overall strategy, we now, in this section, review some of the detail of, and air some qualms concerning, perhaps the most arresting of the three ingredient claims in the *Reason, Truth and History* argument: the claim that even the *truth-conditions* of whole sentences containing them are insufficient to determine the references of subsentential expressions.

The well-known reasoning in support of this claim affirms that given any domain of objects, and a language used to speak about them, the references/extensions of the subsentential expressions of that language may be permuted consistently with invariance in the truth-value assigned at each possible world to – hence in the truth-condition of – each sentence in the language. This is, Putnam suggests – though the claim needs discussion[10] – a generalization of Quine's contention in *Word and Object* (1960) that reference is inscrutable, based on the so-called 'Argument from Below' (see §3 of Chapter 26, INDETERMINACY OF TRANSLATION). However, whereas Quine merely made a suggestive case that, for all our use of whole sentences containing it dictates to the contrary, 'rabbit' might refer to undetached rabbit parts, or temporal stages of rabbits, or the universal rabbithood – thus posing, at most, an unanswered challenge – Putnam's argument is wholly general ('rabbit'

could, without change in the truth-conditions of any sentence containing it, refer to anything whatever) and, if correct, conclusive.

Let us review the illustration Putnam himself gives of the kind of thing that could be involved in such a systematic reinterpretation. Divide all possible worlds into just three kinds:

(a) worlds in which some cat is on some mat and some cherry is on some tree ('is on' is here tenseless)
(b) worlds in which some cat is on some mat, but no cherry is on any tree
(c) all other worlds.

Now fix the reference of 'cat' in a way which depends on which of these three groups the actual world belongs to. If the actual world is a type (a) world, then 'cat' is to refer to cherries and 'mat' is to refer to trees. If on the other hand the actual world is a type (b) world, then 'cat' is to refer to cats, and 'mat' is to refer to mats. Finally, if the actual world is a type (c) world, then 'cat' is to refer to cherries, and 'mat' is to refer to quarks.[11]

Now reflect that, if the actual world is as a matter of fact an (a)-world, in which some cherry is on some tree, the sentence 'A cat is on a mat' will be true when the references of 'cat' and 'mat' are so stipulated. It will likewise be true in any (b)-world, since those are worlds in which some cat is on some mat, and, in those worlds, 'cat' and 'mat' have their customary reference. Finally, in (c)-worlds, the sentence will be false, since no cherry is on a quark. But these valuations, note, coincide exactly with those of 'A cat is on a mat' as ordinarily understood, with 'cat' and 'mat' assigned their customary reference. In short: the sentence 'A cat is on a mat' could have exactly the truth-conditions it does even if, for some possible worlds, including the actual world, 'cat' were to refer not to cats, but to cherries – or whatever you like.

Putnam shows[12] that this type of maneuver can be complicated so as to embrace simultaneously all the sentences of an entire language. And if sub-sentential reference may be varied in a systematic way without shift in truth-conditions, then whatever – if anything – determines reference, it cannot be the truth-conditions of whole sentences.

This conclusion is apt to seem deeply counter-intuitive. After all, are not the semantics of sub-sentential expressions exhausted by their contribution to the meanings of sentences containing them? So does not the reference of a term, or common noun, say, *have* somehow to be distinctively reflected in the meanings of sentences in which it occurs? The argument gives pause, to say the least. We shall review four broad lines of reservation about it.

One quite common reaction is that Putnam's argument is somehow self-defeating. For in order to receive it as showing the existence of alternative interpretations of a language under which all its sentences retain their truth-conditions, we need already to be able to *grasp* the distinctions, generated by permutation, between the various interpretations. But if we can do that – if we can grasp and distinguish from one another the divergent interpretations on offer – then why can't we just *stipulate* that one among them in particular is the correct one? And why won't that stipulation be sufficient to render reference fully determinate? If, on the other hand, we can't make the requisite distinctions, then we are in no position to follow the reasoning by which Putnam seeks to persuade us that there is a difficulty.

It would be no answer to this to suggest that assumptions of determinacy of reference feature in Putnam's argument only for the purposes of *reductio as absurdum*. They don't. The claim that sentences' truth-conditions underdetermine sub-sentential reference, if

supported by showing how particular permutation-based reinterpretations leave truth-conditions invariant, must depend, for its cogency, on a *continuing* grasp of the differences between the assignments of reference respectively involved in the various interpretations – a grasp which is to survive the drawing of Putnam's conclusion, and on which the grounds for that conclusion depend. So the thought may continue to seem impressive: if we understand the differences, then we can stipulate which interpretation is intended.

The main thing wrong with this objection is, rather, that it misconceives the point of Putnam's argument. It assumes that the argument, like Quine's, is properly seen as a *skeptical* one, directed against the determinacy of reference. Now of course, if that were its project, then the argument had better not proceed in a way which effectively presupposes determinacy, or employs materials which can be straightforwardly exploited so as to ensure it. But that is not Putnam's aim. Putnam's aim is to show, rather, that accounting for the determinacy of reference is a problem specifically for a particular kind of philosophical view. Accordingly – just so long as his own position is not vulnerable to the same difficulty – there is no reason why he should not argue in a way that presupposes determinacy. The intended gist of the permutation argument is merely that whatever secures a determinate reference for a particular sub-sentential expression, it is not the truth-conditions of the sentences in which it features. Putnam's position has to be that if any assumption of determinacy of reference is needed by the argument, it is an assumption which will eventually prove quite innocent from an internal-realist point of view. Of course, it's a good question why or whether that is so, and one to which we shall return.[13]

The second reservation is one some critics misguidedly advanced about the argument of "Models and reality"; that is, that the model-theoretic results to which that essay appeals are applicable only to first-order languages.[14] Strictly, this is so. It suffices to remark, however, that no such concern about generality affects the permutation argument of *Reason, Truth and History*. Given a permutation of the referents of the terms and compensating reinterpretation of the predicates of a language which preserves the truth-conditions – that is, the truth-values assigned at each possible world – of each of its *atomic* statements, it is obvious enough that the truth-conditions not merely of first-order quantifications of those statements but also of their second-order generalizations, and indeed modalizations, will be likewise preserved.[15]

Perhaps more surprising is that the result will also extend to languages containing *intentional* operators, in particular expressions of propositional attitude. One might think that there would be a difficulty here, and that the scope of Putnam's argument would consequently have to be restricted. But this is not so. Take the hardest case: suppose that belief, for instance, is treated as a relation between a thinker and a *proposition*, and that any interpretation is required to assign as referent to a that-clause precisely that proposition which, in view of the assignments that interpretation makes to its sub-sentential parts, the clause in question comes to express. Thus, in Putnam's illustration, 'that a cat is on a mat' comes to refer, in (a)-worlds, to the proposition that a cherry is on a tree and, in (c)-worlds, to the proposition that a cherry is on a quark, whilst keeping its usual reference otherwise (that is, in (b)-worlds). How might we set about gerrymandering an extension for 'X believes that' in order to ensure that 'X believes that a cat is on a mat' retains its actual truth-conditions – is true at just the worlds at which it is actually true – while the referents of 'cat,' 'mat,' and 'that a cat is on a mat' vary in accordance with the permutation in (this extension of) Putnam's illustration?

What is required, naturally, is that 'X believes that a cat is on a mat' should express a truth in all and only worlds in which X believes that a cat is on a mat. Now, since both cases are

logically possible, there will be some (a)-worlds in which X does believe that a cat is on a mat and some in which he does not. We require accordingly that X stands, in just the former, in whatever relation the perverse interpretation assigns to 'believes that' to the proposition that a cherry is on a tree, and fails so to stand in just the latter. Clearly, therefore, we cannot leave the interpretation of 'believes that' invariant. For there have to be (a)-worlds in which X does believe that a cat is on a mat but does not believe that a cherry is on a tree, and in such worlds the truth-value of 'X believes that a cat is on a mat' would accordingly change under the permutation. Hence our reinterpretation will have to assign a new relation to 'believes that.' But what relation? Whatever the relation is, it will have to have the feature that *of necessity* a subject stands in it to the proposition that a cherry is on a tree just when he believes that a cat is on a mat. For if this is not a matter of necessity, then again, there will have to be (a)-worlds in which X does believe that a cat is on a mat, but does not stand in the relation in question to the proposition that a cherry is on a tree; and once again the perverse interpretation will get the truth-value of 'X believes that a cat is on a mat' wrong.

One's first thought is that there may simply be no such relation. But *that is not right*. There is, after all, at least the 'Cambridge' relation, in which a subject stands to the proposition that a cherry is on a tree just in case he believes that a cat is on a mat! One might compare this to the relation in which you stand to Mount Rushmore just in case you have seen a photograph of Snowdon. The crucial point is that permutation-based interpretation works *purely extensionally*. From the extensional viewpoint, the latter relation has been fully specified just when what its extension is has been determined; and we have done that. For all and only our readers who have seen a photograph of Snowdon, the extension is the set of pairs, ⟨You, dear such reader; Mount Rushmore⟩. Similarly, the new relation which our perverse interpretation assigns to 'believes' will be one which has, at each (a)-world, an extension including the pair ⟨X; the proposition that a cherry is on a tree⟩ if and only if that (a)-world is one at which X believes that a cat is on a mat. For (b)-worlds – where 'that a cat is on a mat' is assigned as its referent the proposition that a cat is on a mat – no adjustment in the extension of the usual belief-relation is needed (at least, not in respect of X and the proposition that a cat is on a mat). Finally, at each (c)-world – where 'that a cat is on a mat' is assigned as its referent the proposition that a cherry is on a quark – 'believes' will be assigned an extension which includes ⟨X; the proposition that a cherry is on a quark⟩ if and only if that (c)-world is one at which X believes that a cat is on a mat.

This generality in the scope of the permutation argument is very striking. Arguably, however, the main thing one should conclude from it is how little the kind of 'interpretation' here in play has to do with *real* interpretation, as it were – interpretation in any sense which involves the specification of propositional contents which a thinker might conceivably have in mind. This is, in effect, the area of concern of a different line of objection – what we shall call the 'dilute truth-conditions' objection to which we now turn. The objection concerns the ability of the permutation argument, even if this is sound as far as it goes, to deliver a conclusion of the intended significance. Since the goal of the argument, or so it may seem, ought to be to show that the reference of a sub-sentential expression is underdetermined by any features of the *meaning* of whole sentences containing it, Putnam must implicitly take it that he can encapsulate any germane notion of the meaning of a sentence in that of its 'truth-conditions.' To be sure, talk of 'truth-conditions' is, indeed, a standard philosophical idiom for gesturing at sentences' content. But Putnam's argument, the objection claims, works with so dilute a notion of 'truth-conditions' that this connection is subverted. Putnam's notion requires no more of truth-conditional equivalents than coincidence in

their truth-values in all possible worlds – *strict equivalence*, in the sense of C. I. Lewis – and strict equivalence is intuitively quite consistent with manifest differences in semantic structure and content. In particular, their strict equivalence is insufficient to ensure that a pair of sentences make the same contribution to the content of sentences which embed them. Merely to take a pair of strict equivalents which draw on different conceptual resources – say, 'A and B are parallel' and 'Anything perpendicular to A is parallel to something perpendicular to B' – suffices to open up the possibility of someone who knows one but not the other. It follows that the truth-conditions, hence the content, of – to stay with the particular example – 'X knows that A and B are parallel' and 'X knows that anything perpendicular to A is parallel to something perpendicular to B' also differ. If we assume that the content of those two sentences is determined compositionally, there is then no alternative but to view the semantic contributions, and hence the meanings, of 'A and B are parallel' and 'Anything perpendicular to A is parallel to something perpendicular to B' as likewise different. And if there can be more to the meaning – specifically, the semantic contribution to larger, embedding contexts – of a sentence than whatever it shares with its strict equivalents, then the general thought that the references of sub-sentential expressions may be determined by the *meanings* – in that richer sense, whatever it is – of the sentences which feature them is quite passed over by an argument which shows merely that *truth-conditions*, in Putnam's Lewisian sense, don't determine sub-sentential reference.

How may Putnam reply to this? He had better not challenge the inadequacy of strict equivalence to capture certain finer-grained but still intuitive notions of sameness and difference of sentence meaning. Rather, what he ought to query is the stated characterization of the goal of the permutation argument: we should take the goal of the argument, that is, as that of showing, not that the reference of sub-sentential expressions is underdetermined by *any* features of the semantics of whole sentences containing them, but that sub-sentential reference is underdetermined by any whole-sentence semantical features *which can be explained without prior reliance on specific relations of sub-sentential reference*. That the reference of sub-sentential expressions might yet be recoverable from certain finer-grained semantical properties of sentences containing them – finer-grained than can be captured by relations of strict equivalence and non-equivalence – is accordingly, Putnam may charge, in no way inconsistent with his goal. For what goes into the constitution of such finer-grained semantic properties of a sentence will be, broadly, its mode of composition and the semantics – including reference – of its sub-sentential ingredients. Indeed, it is unintelligible how sentences could have such finer-grained semantic features in the first place unless we simply take for granted a gamut of relations of reference between sub-sentential expressions and items in the world. In short: the reply should be that while there may indeed be finer-grained conceptions of sentence meaning than Lewisian strict equivalence, and while the reference of a particular sub-sentential expression may be recoverable from the finer-grained semantics of sentences containing it, this is all back to front from the point of view of answering Putnam's challenge. That challenge is to explain wherein the determinacy of sub-sentential reference is *constituted*. It is therefore irrelevant to appeal to semantical features of whole sentences which themselves depend upon the reference of those sentences' constituents.

Now, there is a possible misgiving about this reply connected with the question, mentioned earlier, of the extent of the analogy between Putnam's argument and Quine's 'Argument from Below.' The points of analogy are that the conclusion of both Putnam's and Quine's arguments may be expressed in the same way, that we can hold fixed the truth-conditions of a

sentence while varying the reference of semantic constituents within it; and in both cases such constancy of truth-conditions may be glossed as consisting in the fact that, no matter how the world actually happens to be, the sentence will retain – after reference-permutation or Quinean reinterpretation, respectively – the same truth-value as that secured for it by the (presumed) actual reference of its semantic constituents. However, Putnam's illustration would also seem to point to a potentially important difference. The kind of reinterpretation illustrated by the cats-and-cherries example sustains continuity in truth-value only because it is required to be sensitive to *what is actually the case*: for instance, 'a cat is on a mat' is true, under the illustrated reinterpretation, in both type (a)- and type (b)-worlds only because what it says is *constrained to vary* as a function of which, if either, of those types the actual world belongs to. By contrast, any of Quine's alternative translation schemes for 'gavagai' (see §3 of Chapter 26, INDETERMINACY OF TRANSLATION) will construe what the sentence says *in a uniform manner*, no matter what the actual world is like. In short, you cannot tell, under Putnam's assignment of reference, what 'a cat is on a mat' says unless you know how relevant matters stand in the world. But no such knowledge is needed to know the impact on 'gavagai' of any particular one of Quine's schemes. What follows is that for Putnam, but not for Quine, an *additional* distance would seem to be opened between preservation of truth-conditions and preservation of content: precisely, 'a cat is on a mat' retains its actual truth-conditions under the illustrated permutation – that is, has the truth-value it would actually have no matter which of the three types of world the actual world belongs to – only because what it says is *made to change* depending on which type of world that is. And while it may be acceptable for the argument to ignore differences in truth-conditions which can only be specified by presupposing differences in – and hence determinacy of – sub-sentential reference, it is still vital that the notion of 'truth-conditions' which it employs be as strong as possible consistently with that limitation. Yet the notion of sameness of truth-conditions at work in the permutation argument would seem to have *even less connection* with sameness of meaning than strict equivalence does.

This development of the dilute truth-conditions objection probably ought to be open to just the same counter as the original objection. Suppose the objection is right that there is a perfectly good sense in which the effect of a Putnamian – in contrast to a Quinean – reinterpretation will be to have the *content* of a sentence vary as a function of what is actually true. The crucial question, however, is whether this variation in content could be appreciated from a standpoint which takes nothing for granted about sub-sentential reference, but is apprised only of *independently appreciable* semantic properties of whole sentences. What can be known about the semantics of a sentence by someone who knows nothing about the reference of its constituents? Could such a subject know more than its Putnamian truth-conditions, in which possible worlds it would be true and in which false? If not, then the claimed disanalogy between Quine and Putnam would not matter; the permutation argument would still be working with the strongest relevant notion of truth-conditions. Now there are, of course, things other than its Putnamian truth-conditions which someone can know about the semantics of a sentence who does not yet know anything about the reference of its constituents. In particular, there are all the things that are allowed to be available as data for a radical interpreter. Thus it is open to someone who does not yet know the reference of the constituents of 'a cat is on a mat' to observe its *use*, and to note in particular what appear to be its conditions of warranted assent. What he will observe if 'cat' refers to cats and 'mat' to mats is that the circumstances which prompt assent will tend to be those in which some cat is on some mat in a fashion salient to the assentor. But then, as may seem

obvious – indeed, the whole point of Putnam's trick – the same pattern will still be expectable if 'cat' and 'mat' are assigned reference as in his illustration. For suppose that is so and you are asked to assent to or dissent from 'a cat is on a mat.' Isn't it still true that you have only to consider whether you have reason to believe that a cat is on a mat? For if you do, then in both cases – when a cherry is on a tree (in which case that is what the sentence will say) and when none is (in which case it will say that a cat is on a mat) – you will have reason to think that 'a cat is on a mat' is true. So, of course, your observable pattern of assent will be the same.

Prima facie, then, the additional dilution would not matter in any case. However, the decisive point is that, as the proofs in the Appendix to this chapter make clear, its apparently additional dilution of the notion of truth-conditions is actually an artefact of a dispensable – and it has to be said, misleading – feature of Putnam's illustration. There is no need for a permutation-based reinterpretation to 'kink' the assignments of reference after the fashion of the cats-and-cherries example. To be clear about this, consider a specific domain of objects, D, and, for simplicity's sake, restrict attention to all possible worlds involving just those objects and no others. Suppose we have a language, L, fitted to talk about the elements of D and to ascribe a given range of simple properties of them. A permutation of such a domain is simply a one-to-one mapping of D onto itself in such a way that no object need be correlated with itself; and the reinterpretation of the terms and (1-place) predicates of L associated with such a permutation does no more than have each term of L refer to the object onto which the permutation takes its actual referent, and have each predicate of L take as its new extension the set whose members are exactly the objects onto which the permutation takes the objects in its actual extension. Clearly, no matter what the actual extension of a predicate may be, the actual referent of a term will be a member of it only if its correlate under the permutation is a member of the set assigned to that predicate under the permutation-based reinterpretation. Although certain complications have to be finessed to take account of variation on the domains associated with different possible worlds, and of more complex predicates, this simple train of thought captures the essence of the permutation argument. And it points directly to a *uniform* reinterpretation of each sentence 'Fa' of L which is guaranteed to preserve its truth-value in any possible world. Where p is the permutation in question, that reinterpretation will read along the lines of 'the p-correlate of a is a member of the set of p-correlates of Fs.'

We conclude that Putnam has the resources to handle the dilute truth-conditions objection. But there is a related and fundamental worry still outstanding. The immediate effect of the permutation argument is that truth-conditions in, as we have seen, a somewhat technical sense underdetermine sub-sentential reference. And this result, we have stressed, is not to Putnam's purpose unless it bears interpretation as showing that all aspects of the use of a sentence that might be observed without presupposition about the reference of its constituents underdetermine what that reference may be. Now Putnam himself repeatedly expresses his finding as being that reference is underdetermined by both observational *and theoretical* considerations (see, e.g., Putnam, 1989, p. 215). That is a very strong claim. It is tantamount to claiming not merely that alternative assignments of sub-sentential reference are *consistent with* all possible uses of a sentence, but that there will be *nothing to choose between them* even when one takes account of all constraints, beyond empirical adequacy, which condition the construction of semantic theory. This has manifestly not been shown. It hardly seems likely, for instance, that, when all theoretical constraints on interpretation have been reckoned with, there still will be nothing to choose between interpreting speakers as

expressing thoughts of the form: object a is F, and interpreting them as expressing thoughts of the form: the *p*-correlate – for some permutation, *p*, of the domain – of a is a member of the set of *p*-correlates of Fs! (For more on relevant such wider interpretational constraints, see Chapter 26, INDETERMINACY OF TRANSLATION, §5.) In order for the permutation argument to succeed in showing that *best* interpretation of the use of whole sentences always has a variety of schemes of sub-sentential reference to select from, we have to be shown how to find *alternative extensionally coincident thoughts* to correspond to such monstrosities about *p*-correlates and sets of *p*-correlates – alternatives which it is as plausible, in the light of all relevant theoretical constraints, to interpret a subject as expressing by 'Fa' as the simple thought that a is F; and we have to be shown how to do this in a systematic way, right across the language. In short, to make good the suggestion that whole-sentence use underdetermines sub-sentential reference, permutation-based reinterpretations have to be shown to be, by *all* relevant constraints, as good – or anyway to facilitate reinterpretations which are as good – as standard interpretations. The results about permutation, by themselves, are powerless to show that is so.[16]

IV

We turn now to Putnam's argument that the intentional states of speakers are insufficient to determine the reference of their words. The argument, as we saw, proceeds by dilemma: if intentional states are conceived as 'pure' – so that, for instance, speakers both on Earth and Twin Earth can express the very same belief by 'Water is wet' – then reference may vary even though intentional states remain the same. If, on the other hand, intentional states are taken to be impure, so that the content of the belief that 'Water is wet' will be a function of the actual environment of its holders, then beliefs are now individuated by the actual references of the terms that occur in their expression, and thus presuppose, rather than constitute, such facts.

One cause for concern is whether the considerations offered in support of the first horn of Putnam's pure/impure dilemma can be made to cohere with what, later in the argument, he will want to say about the insufficiency of the sort of naturalistic conception of reference to which some – Hartry Field is an actual case[17] – may be tempted in response to Putnam's overall argument. To appreciate, after all, how reference may vary across environments in which the pure mental states of subjects remain the same, one has to have some conception of how reference *functionally depends* on environmental factors. But if such a conception is in place, then won't it constitute at least the beginnings of an account, independently of any play with speakers' mental states or the truth-conditions of sentences, of what it is that does determine reference? – precisely the kind of account which, according to the third stage of Putnam's argument, cannot be given. Unquestionably there is a fair interpretative question here. The externalism about content which the first horn of the dilemma employs is a long-term theme in Putnam's writing; yet the metaphysical realist is apparently to be denied access to this element in Putnam's own philosophy in his attempt to respond to Putnam's challenge. However, we are entitled to proceed without pursuing that question by the consideration that this part of Putnam's argument in any case has no need to proceed in terms of the pure/impure dilemma.[18] A much simpler reflection will suffice. In order for speakers' intentional states, of whatever sort, to serve to establish the references of linguistic expressions, it has to be the case that the objects assigned to those expressions as their referents are

already given as *objects of thought*. It is only as thought about – as referred to in thought – that we can fix, or understand, what it is for a particular object to be the referent of a particular symbol. But the constitutive question being put to the metaphysical realist arises no less for thought than for language. The challenge is to give an explanation of what it is for our thoughts to be of certain objects, rather than others, in the first place. The fact is, accordingly, that there never was any real option of the kind which the pure/impure dilemma is supposed to address. Intentional states cannot constitute reference. That our intentional states already have reference is (an aspect of) the problem, not its solution.

V

If the first two stages of Putnam's argument were to succeed, then the situation would be that no satisfactory constitutive account of reference can proceed in terms of facts concerning our intentional states, or facts about the truth-values, or even truth-conditions, of complete sentences or thoughts. To a metaphysical realist who is also a materialist, however, such conclusions would likely be entirely congenial, merely serving to underline the need for a quite different account of reference in broadly naturalistic terms. That it would be quite mistaken to think that any such account could meet metaphysical realism's needs is the burden of the third component of Putnam's argument.

This comprises, in fact, several distinguishable lines of attack: some of them are directed specifically at the idea that reference can be fixed by causal connections, but others aspire to greater generality, purporting to establish that there can be no 'reductive' explanation of reference in naturalistic terms or, more generally still, that once it is allowed that neither intentional states nor truth-conditions can form the basis of an explanation of how reference can be determinate, it can be seen that nothing else can do so either. The concern of this section will be with the most general – and most notorious – such line of all.

Putnam writes:

> Suppose there is a possible naturalistic or physicalistic *definition* of reference, as Field contends. Suppose
>
> (1) *x refers to y* if and only if *x bears R to y*
>
> is true, where *R* is a relation definable in natural science vocabulary without using any semantical notions … If (1) is true and empirically verifiable, then (1) is a sentence which is itself true even on the theory that reference is fixed as far as (and *only* as far as) it is determined by operational *plus* theoretical constraints ….
>
> If reference is only determined by operational and theoretical constraints, however, then the reference of '*x bears R to y*' is itself indeterminate, and so knowing that (1) is true will not help. (Putnam, 1981, pp. 45–46)

Knowing that all instances of (1) are true won't help, Putnam thinks, because, by the permutation argument, they will remain true – and, indeed, will have the same truth-values in all possible worlds – when 'R' is taken instead to stand for a quite different relation R*. In fact, there are as many such alternatives R* as there are permutations of the universe of discourse. So supposing reference to be R has no more explanatory merit than supposing it to be R*. Hence it is merely an illusion that a unique reference relation has been singled out.

This move – of holding any attempted naturalistic characterization of reference to be 'just more theory' hostage to permutative reinterpretation – is one that Putnam repeatedly

makes in the closing stage of his various attacks on metaphysical realism.[19] If allowable, it is of course decisive – for it will be available against *any* specific constraint the metaphysical realist may propose, regardless of its precise content, just so long as the constraint is formulated in a language to which the permutation argument applies.[20] The obvious and crucial issue is: Is the move fair, or foul?

Well: it is foul, for a reason first stressed by David Lewis (1984, pp. 224–225). There is a distinction to be made between, on the one hand, an interpretation's *modeling* a proposed constraint – *making a statement of the constraint come out true* – and on the other, the interpretation's *actually conforming to that constraint*. The 'just more theory' gambit seems simply to miss this crucial distinction, taking the former for the latter.

To elaborate a little: Let C be some proposed (naturalistic) constraint on reference generally, L a language, S a sentence of L expressing C, and I an interpretation of L. Suppose that I does indeed induce the value *true* on S. It might seem that I must conform to C; for S expresses C, after all, so that if I makes S come out true, isn't that just the same thing as I's conforming to C? Well obviously, not at all: we have no right to assume that, *whatever interpretation* of L is in play, S will (still) express C. Suppose, schematically, that S has the form:

$$\forall x \forall y \forall z(\text{speaker}(x) \,\&\, \text{expression}(y) \,\&\, \text{object}(z)) \rightarrow (x \text{ refers to } z \text{ by } y \rightarrow R(x,y,z))$$

One thing that may vary under different interpretations of L is, naturally, the relation assigned to 'R.' We may not take S as expressing C *tout court* – some interpretations will have S expressing C, others won't. An interpretation J under which S fails to express C may still make S come out true. And if we are able to express C in some other language L*, with resources sufficient to discuss the semantics of L, we may be in position to state – and it can be true – that while S is a sentence of L true under J, J does not conform to C.

A supporter of Putnam might reply that this will be a situation we can recognize as obtaining, and to which we can give expression, if, *but only if*, we can fall back on some other language L*, the reference of whose expressions can be assumed to be (sufficiently) determinate – in particular, there will have to be a sentence of L* by means of which we can give determinate expression to the intended constraint C. And it is precisely at this point, it may be alleged, that the metaphysical realist runs into 'just more theory' trouble. For his predicament is that any language, L* no less than L, will raise just the same problem about determinacy of reference. He can't just assume a more inclusive but referentially determinate L* in which it may be asserted that whilst the sentence S does indeed come out true on a whole host of interpretations (of L), all but a few of these are ones under which S fails to express the proposed constraint, to which they, furthermore, fail to conform. And if he can't simply assume that he can convey this thought in words, he cannot assume that he can think it either.[21] The upshot is, the supporter may claim, that while there is indeed a distinction of the sort Lewis proposes, the metaphysical realist cannot avail himself of it in the situation which matters, when any metalanguage, no less than the language with which we are originally concerned, gives rise to just the same difficulty.

But if this is the best reply that can be made, Lewis is right to cry "Foul!" Just consider the dialectical situation. The metaphysical realist – Field or Devitt, for example – takes up the challenge to say what constitutes determinate relations of reference, only to find that no sooner has he opened his mouth than Putnam gags him with the complaint that he has no right to assume any of his words to be determinate in reference. The resulting situation is therefore really no different from that generated by the boring and jejune variety of

meaning-skepticism which challenges an opponent to explain how meaningful discourse is possible, but won't countenance attempted answers because to presume them meaningful is to beg the question against it. Obviously the metaphysical realist has to be presumed capable of contentful – so, determinately referential – speech if he is to respond to Putnam's challenge, or indeed to any challenge at all. The onus legitimately placed upon him is not to *demonstrate that* determinate reference is possible, but to provide a constitutive account which *explains how* determinate reference works. Accordingly, he is perfectly within his rights to assume, at least *pro tem*, a metalanguage in which a determinate account of the putative mechanics can in principle be given.

VI

If the 'just more theory' move is illicit, that need still be no very serious matter for the overall argument, provided there are good independent reasons for doubting that any naturalistic reduction of reference can be provided. Putnam has assembled in different places a variety of more specific arguments to this conclusion, of – so it seems to us – somewhat differing levels of cogency. We shall briefly review two lines in particular.

The first occurs in "Model-theory and the 'factuality' of semantics" (1989). The form of naturalistic proposal Putnam there envisages is familiar from such natural scientific identifications as those of water with H_2O or of heat with mean kinetic energy of molecules. By identifying heat with mean molecular energy of motion, we accomplish what seems to be the best available explanation of empirically attested correlations involving variations in the temperature and pressure of a mass of gas whose volume is kept constant and so forth, and take this to sanction the identification. Might it not be, likewise, that by identifying the relation of reference with a certain physical relation, R, holding between tokenings of expressions and the worldly items to which they refer, we may achieve the best explanation of certain aspects of our use of those expressions? That is, why should ordinary scientific methodology not turn out to provide the same kind of case for identification of reference with R as for the identification of water with H_2O, or heat with mean molecular motion? (cf. Putnam, 1989, pp. 216–217).

Putnam's objection[22] is that any such proposal, grounded upon explanatory virtue, is viciously circular. Here is a key passage:

> One difficulty … is that this [proposal] uses the notion of *truth*. Our problem … was to explain how a particular reference relation – and that means, also, a particular extension for the notion of truth – gets attached to our words. To say that what does the attaching is the fact that certain sentences … are *true*, … is flagrantly circular. The problem, of course, is that what the semantic physicalist is trying to do is reduce intentional notions to physicalist ones, and this program requires that he not employ any intentional notions in the reduction. But *explanation* is a flagrantly intentional notion.[23]

We can discount what may seem to be the principal complaint in this passage. The general shape of the type of proposal mooted is that it is because a certain physicalistically specifiable relation R holds between our words and their referents that those words do in fact have those referents. It is, therefore, simply a misrepresentation to treat the proposal as asserting that the fact that certain *sentences* are *true* is what explains why our words refer as they do.

That is, it seems quite gratuitous to impute to the physicalist the contention that what 'does the attaching' is the fact that a certain sentence (saying that our words bear R to some object) is true, rather than (simply) the fact which that sentence purports to state. This indifference to the distinction between object- and metalinguistic claims merely invites repetition of the main complaint already leveled at the 'just more theory' move.

The point about explanation made in the second half of the passage may seem more telling: if the semantic physicalist is in the business of giving a reductive account of reference in particular, and intentional notions in general, how can it be permissible to deploy intentional notions in so doing? But this too seems to us of doubtful force. Maybe the question would be appropriate if what was at issue was the standard type of *analytic* or *conceptual* reduction, a purported analysis of necessary and sufficient conditions of application. But the mooted form of proposal actually seeks an *a posteriori* reduction. It is anything but clear that all use of the notion of explanation must be eschewed, if the aim is that of saying what naturalistic relation between words and things in fact underpins reference – if what's on offer is a *theoretical* identification of reference with R, of the same general character as the identification of heat with mean molecular motion.[24] All it seems to be legitimate to impose, by way of a general constraint, is rather that if use is made of an intentional notion in a statement which is part of a program of physicalistic reductions of intentional notions generally, that use must be of a kind ultimately amenable to that form of reduction. It would be necessary to look at the details to see whether a particular physicalistic construal of reference, or explanation, violated this rather vague constraint. In any case, the constraints on legitimate *a posteriori* identification of properties and relations still remain to be clearly worked out.

Putnam is on much stronger ground, however, if it may be assumed that the naturalist proposal must ultimately identify reference with some *specific form of causal relationship* between the item or items that stand as the reference of a term and token uses of that term. Putnam himself, of course, has been prominent among those who have emphasized, as against the once orthodox Fregean conception of the matter, the role of causality in the determination of reference in a wide class of cases. But he warns us that neither his own proposal, nor Kripke's similar idea, were intended to explain from a standing start, as it were, how determinate reference is constituted; clearly they could not do so, since both pictures simply assume from the outset that individuals can be "singled out for the purpose of a 'naming ceremony,'" and say nothing about how that might be done *ab initio*.[25]

Putnam has expressed various doubts about the viability of a reductive causal theory of reference. As he stresses, it will normally be the case that very many of the objects and events that figure in the causal ancestry of a particular utterance of an expression will not be what it refers to. Further, a term's or predicate's reference may be to, or may include, things with which it is not causally linked – items existing only in the future, for instance, are presumably available to be referred to but as yet sustain no causal relations.[26] Part of the problem for the causal theorist, then, is to single out the right causal relationship. Putnam is skeptical that this can be done in purely naturalistic terms without falling back on intentional notions. As against Evans's version of a causal theory, for example, according to which, roughly, a term refers to the dominant source of our beliefs involving it, he justly observes that the dominant source of our beliefs about electrons, say, may well be physics textbooks, rather than electrons themselves.[27]

Obviously these considerations are not conclusive. To the difficulty about future things, for example, it may be replied that in cases where the term introduced is general (perhaps a natural-kind term) it is to be understood that its extension comprises the causally connected

samples and all other things of the same kind.[28] In general, causal theorists will surely agree that work is needed to characterize the appropriate kind of causal link – but why suppose the project to be hopeless?

Well, we suspect the project is hopeless. The core difficulty is to restrict, without ineliminable play with antecedent assumptions about its reference, the utterly disorderly mess of items that are apt to elicit tokenings of any given expression. In his Gifford Lectures (Putnam, 1992, ch. 3) Putnam discusses probably the most sophisticated attempt to date to accomplish this: the proposal of Jerry Fodor (1990) that the extension of a term comprises the smallest class of items which as a matter of natural law cause tokenings of the term, and whose doing so asymmetrically explains all other tokenings of the term. For example, both horses and pictures of horses are apt to cause tokenings of 'horse'; but Fodor's intuition is that horses are the basic cause and therefore qualify as the reference, since it is only because horses cause tokenings of 'horse' that pictures of horses do.

Against this, it may be objected that there really is no clear priority as between 'If horses did not cause tokenings of "horse," neither would pictures of horses' and 'If pictures of horses did not cause tokenings of "horse," neither would horses.' Rather, what seems to be true is that it is because 'horse' refers to horses that *both* horses *and* pictures of horses – and thoughts of horses, and cows in a darkened field, and so on and so forth – elicit, *ceteris paribus*, tokenings of 'horse'! In the jargon of possible worlds, the closest worlds in which pictures of horses do not cause tokenings of 'horse' are worlds in which horses don't either.[29] (For a fuller discussion of difficulties with semantic naturalism, see Chapter 8, A GUIDE TO NATURALIZING SEMANTICS.)

VII

Let us try to take stock. First, to summarize the situation of the three sub-arguments of *Reason, Truth and History*. That the metaphysical realist has no option of explicating reference in terms of intentional states we take to be clear. However, the claim of the permutation argument to have shown that reference is underdetermined by features of the use of whole sentences is, as we saw, open to question. Moreover, the 'just more theory' move *is* a foul, and some of Putnam's own specific criticisms of causalist/naturalist proposals about reference are less than conclusive. However, to observe that the permutation argument as it stands is inconclusive for Putnam's purpose is one thing; but to make the kind of positive, constructive case for the determination of reference by whole-sentence semantics which, if such was her strategy, the metaphysical realist would need, is quite another. It is no clearer how such a case might in detail be made. Moreover, if that is not to be the strategy, then a causal account of reference – broadly construed – is the only remaining avenue to explore, yet the literature justifies nothing but pessimism about reconstructibility of semantic notions in non-intentional, causal terms. Putnam, then, may not have strictly proved all of his three lemmas. But he has done enough to issue a very pointed challenge, and one to which it is by no means clear that the metaphysical realist can satisfactorily respond.

Second, it merits emphasis that Putnam's considerations, even if conclusive, would provide no argument for the indeterminacy of reference as such; rather, what they would establish is that *if* referential relations had to be constituted in a certain kind of way – in the truth-conditions of sentences, for instance, or in causal connections – *then* reference would be indeterminate. The proper conclusion would be merely that a constitutive account of

reference, of what makes it the case that a particular term, thought or spoken, stands for a particular object or kind, cannot proceed along any of the three lines reviewed. If those lines indeed exhaust the possibilities, then a case would have been made that there can be no fully explicit, reductive account at all of what constitutes the reference of a symbol to any particular item or range of items – at least, none which does not take for granted the determinacy of reference of our thoughts as a background. 'Aboutness' would have to be conceived as primitive.[30]

Such a finding would no doubt be of great interest. But it will have been achieved, if it can be achieved, in a way that has no evident selective bearing on the status of metaphysical realism. The argument, if it can be made good, will be an argument for everybody. Moreover, notions which promise to admit of no reductive account are anyway ten a penny. So the questions remain: Why see in the situation a (potential) *problem* to do with reference? And why, if so, a problem *distinctively* for *metaphysical realism*? The crucial task for a would-be sympathetic interpreter of Putnam is to provide convincing answers to these questions. How might such answers run?

To lack a constitutive account – and all prospect of a constitutive account – of a certain kind of subject-matter is not, except in special circumstances, to have a reason to distrust its reality. That Putnam himself intends no skepticism about reference is abundantly clear from his willingness to allow that we can perfectly legitimately and fully adequately specify what 'cat,' for instance, refers to: its reference is to *cats* (and therefore not to cherries, or to the *p*-correlates of cats under some permutation, *p*)! More generally, if it is granted that the language in which we are to state the reference of a term is an extension of the language to which that term belongs, then a homophonic formulation is a perfectly adequate response to someone who challenges us to individuate the reference of that term. If, however, that assumption is not granted – that is, if object- and metalanguage are distinct and the challenge is to justify the assignment of one scheme of reference to the terms of the object language, rather than to a permutation of it – then there are perfectly ordinary canons of interpretation to justify a preference, for example, for the assignment of cats to be the extension of 'chat' in French, rather than cats* – that is, cherries in a world in which cats are on mats and cherries are on trees. These will be canons which have to do, for instance, with the salience of cats in many of the situations which provoke 'chat'-talk among the French and a corresponding salient absence, for the most part, of cherries. That there are correct and incorrect things to say about what expressions refer to is enough for there to be *truths* – at least on the conception of truth favored by the internal realist – about reference.

This is the key to the question of the selective bearing of the argument. What, precisely, might be put in doubt by the kinds of consideration reviewed is the existence of truths about reference *in a more substantial sense of* 'truth,' a concept of truth whose applicability to claims of a certain kind requires, beyond the unimpeachability of those claims in the light of the ordinary discipline that informs their use, some form of robust *fit* between them and the world. For it is not enough for metaphysical realism merely that there be facts about what the expressions of our language refer to: these facts must be facts as metaphysical realism is wont to conceive *all* facts, facts no less sublime than – since constituted by relations to – the sublimated objects and properties which make up the metaphysical realist's world. There is accordingly no question of resting content with the sort of deflated account of them which is all that is provided by the homophonic platitudes and routine methodology of interpretation for which the internalist about truth may settle.

The metaphysical realist, then, owes a perspective on the nature of relations of reference which allows them to stand behind the routine interpretative methodology and which, indeed, explains its adequacy – explains how it is indeed a way of 'getting onto' or 'tracking' these independently constituted relations; a perspective which allows us to construe the truth of ascriptions of reference along robust correspondence lines, and which generally finds a place for such relations in the world as metaphysical realism conceives it. And there is, if Putnam's argument can succeed, no such perspective possible, because there is then nothing to be said about what reference *is*.[31]

In brief, then, we have a rich and complex argument to the conclusion that reference admits of no reductive account, coupled with the claim that metaphysical realism – but not internal realism – is saddled with a world-view that cannot be properly understood unless such an account can, *per impossibile*, be given. The crucial difference is entirely one of explanatory obligation. For metaphysical realism, reference is a matter of relations between robustly distinct existences, items of language and thought on the one side, and items in a stubbornly alien world on the other; and this conception, Putnam's driving idea has it, entrains a commitment to the possibility of some sort of external perspective on the nature and constitution of this relationship – exactly what, if his argument succeeds in detail, cannot be delivered. So the metaphysical realist must, in the end, be driven to obscurantism: a conviction in the reality of relations constituted, he knows not how, between his thought and a world wholly alien to it.[32]

VIII

Why does internal realism incur no parallel obligation? Can the mere currency of standards of correctness for claims about reference really ensure that no issue arises? It is one thing to get a sense of Putnam's thought on this point, another to determine whether it is really convincing. The key idea seems to be that, as Putnam repeatedly expresses it, 'there is no ready-made world': that the division of the world into particular objects and kinds of thing is somehow coeval with, rather than merely *reflected by*, the divisions among our concepts and the expressions for them. If the kind picked out by a term of ours is thought of as originally constituted quite independently of the use of that term and the conceptual resources associated with it, then the question has to arise: What attaches the term on to just that kind, as opposed to another? That is the question which metaphysical realism is charged to answer. If, by contrast, the kind is regarded as in some way having no being independently of our deployment of those very conceptual resources, then there is no real linkage to explain, any more than it wants an explanation, how the patterns on a slide manage to be congruent with the images it casts upon a blank screen.

This kind of simile is convincing enough in its way. The difficulty is to give it substance in the case that matters – to see what the idea that human conceptual activity 'slices up' the world really comes to.[33] But perhaps on reflection there is room to repudiate the metaphysically realist conception of a 'hooking' of language onto a sortally predeterminate world without recourse, natural though it may be, to opposing constructivist metaphors.[34] The crucial point is that, unless the unity of a range of items is in some way fixed in advance of the institution of using a term of which they are the reference, there is no non-trivial question what makes for the connection between that term and that range: the range of items in question just constitutionally is that for which the term in question stands.

That leaves the metaphysical realist the options of faulting the detail of the stages of the argument, or living with its conclusion: that to conceive of the world in a certain kind of robustly autonomous fashion is to consign the relation between the vehicles of our thought and the taxonomy of the world to unaccountability. Putnam effectively ridicules such an upshot. But ridicule, it may be countered, is no substitute for argument. Any broad philosophical system will have its primitive notions and theses. Further argument may be demanded as to why metaphysical realism may not legitimately go primitive at the interface between language and the world. That is what it must do if intentionality – 'aboutness' – is indeed irreducible, as in effect the three ingredients of Putnam's argument combine (if they are sound) to show. To be sure, no aspirant to a purely physicalist version of metaphysical realism could rest content with primitively intentional relations of aboutness. And Putnam may be right to say that "materialism is the only *metaphysical* picture that has contemporary 'clout.' Metaphysics, or the enterprise of describing the 'furniture of the world' … has been rejected by many analytic philosophers … Today, apart from relics, it is only materialists (or 'physicalists,' as they like to call themselves) who continue the traditional enterprise."[35] But it remains to be convincingly explained why "the only sort of metaphysical realism that our time can take seriously" (Putnam, 1989, p. 220) should be a thorough-going physicalism, or why irreducible intentionality should be especially uncomfortable for one of metaphysically realist predilection.

We end with one final reservation about the scope of the argument. If the interpretation offered is sound, then it can engage only a realist who accepts the autonomy of the division of the world into objects and kinds. So far as we can see, it must therefore fail to touch an intermediate, apparently coherent combination of views: the combination which yokes rejection of the idea that there is a 'pre-sliced,' 'ready-made world' – that the world divides into kinds of thing, stuff, and so on quite independently of our efforts to devise a conceptual scheme in terms of which it may be best described and understood – with acceptance of an evidentially unconstrained conception of truth, that is, with realism in the sense Dummett has made familiar (see Chapter 20, REALISM AND ITS OPPOSITIONS). Putnam has sometimes written as if the latter form of realism must fall to his argument. If we are right, that can be so only if a Dumettian, realist conception of truth must in the end consist in the kind of robust correspondence conception which is the essence of metaphysical realism as Putnam conceives it. However, it is one thing to accept that questions about what words refer to make sense, and have determinate answers, only within a conceptual scheme (so that the words cannot be thought of as having reference to an antecedently determinate world of objects and kinds), and another to claim that we cannot combine those words into statements which may, in principle, possess determinate but undetectable truth-values. If the latter *is* a consequence of the former, further argument is needed to show it.[36,37]

Appendix: Permutation Results

In his Appendix to *Reason, Truth and History*, Putnam shows how to prove a relatively strong permutation result to the effect that, given an interpretation I of a (first-order) language L, we can construct another ('unintended') interpretation J which preserves the truth-conditions of all the sentences of L (in his sense, under which sentences have the same truth-condition if they have the same truth-value at all possible worlds), whilst varying the extensions of terms and predicates. Here, we first prove a more basic, weaker result

(to the effect that, given an interpretation of a first-order language, we can always construct an alternative 'unintended' interpretation which coincides with the given interpretation over the truth-values of all the sentences, while varying the extensions of terms and predicates). We then indicate how the method of proof (which differs somewhat from that employed by Putnam) may be extended to obtain, first, a result essentially the same as Putnam's and then some stronger results, for second-order languages and for languages with modal operators.

Weak Permutation

For this, we work with a first-order language L, with logical constants: ¬, ∧, ∃; terms, comprising individual constants a, b, c, … and variables x, y, z, … ; and predicate constants F, G, H, …. The atomic sentences are just the strings $Ft_1, \ldots, t_n$, consisting of an n-place F followed by n occurrences of individual terms. If A,B are sentences, so are ¬A, A ∧ B, and ∃xA(x), where x is any variable and A(x) comes from some sentence A by replacing one or more occurrences of some one individual constant by occurrences of x.

An interpretation I of L consists of a non-empty domain D with assignments of elements of D as denotations of the individual terms and of sets of ordered n-tuples of elements of D, for appropriate choices of n, as extensions of then-place predicates. Thus to each 1-place predicate, I assigns as extension a subset of D – intuitively, the set of elements of D having the property for which, under I, that predicate is taken to stand; to each 2-place predicate, I assigns a set of ordered pairs of elements of D – intuitively, the pairs of elements of D the first of which bears to the second the relation for which, under I, that predicate stands, and so on. 'I(A) = 1' denotes that A is true under I, and is defined as follows:

$I(Ft_1 \ldots t_n) = 1$ iff $\langle I(t_1) \ldots I(t_n) \rangle \in I(F)$

$I(\neg B) = 1$ iff $I(B) \neq 1$

$I(B \wedge C) = 1$ iff $I(B) = I(C) = 1$

$I(\exists xB(x)) = 1$ iff there is an interpretation I° which differs from I at most in its assignment to x, such that $I^{\circ}(B(x)) = 1$

Theorem 1 (weak permutation)

> Let I be any interpretation with domain D, and ϕ be any permutation of D. Let I* be any interpretation with the same domain D such that, for every term t, $I^*(t) = \phi(I(t))$, and for every n-place F, $I^2(F) = \{\langle d_1, \ldots, d_n \rangle \mid \langle (\phi^{-1}(d_1), \ldots, \phi^{-1}(d_n) \rangle \in I(F)\}$. Then for any A, $I(A) = 1 \leftrightarrow 1^*(A) = 1$

Strictly, for the purposes of Putnam-type arguments, we need only establish that for given I, D, and ϕ, there is at least one interpretation meeting the specified conditions on I*, for which the theorem's consequent holds. However, the proof can proceed more smoothly for the theorem as stated. It is obvious that there *are* (non-trivial) interpretations meeting the antecedent conditions.

Proof is by induction on the degree of A, as measured by the number of logical operators occurring in it. So the induction hypothesis (IH) is that the theorem holds for all wffs of

degree < A, and on this hypothesis it is to be proved that the theorem holds for A. More fully stated, IH is:

> If I^1 and I^2 are *any* interpretations with the same domain, such that for each term t, $I^2(t)=\phi(I^1(t))$ and for any n-place F, $I^2(F) = \{\langle d_1, \ldots, d_n \rangle \mid \langle \phi^{-1}(d_1), \ldots, \phi^{-1}(d_n) \rangle \in I(F)\}$, then for any B of degree < A, $I^2(B) = 1 \leftrightarrow I^1(B) = 1$

A is atomic, that is, $Ft_1 \ldots t_n$ for some n.

$$
\begin{aligned}
I^*(Ft_1 \ldots t_n) = 1 \quad \text{iff} \quad & \langle I^*(t_1) \ldots I^*(t_n) \rangle \in I^*(F) \\
\text{iff} \quad & \langle \phi(I(t_1)) \ldots \phi(I(t_n)) \rangle \in I^*(F) \\
\text{iff} \quad & \langle \phi^{-1}(\phi(I(t_1))) \ldots \phi^{-1}(\phi(I(t_n))) \rangle \in I(F) \\
\text{iff} \quad & \langle I(t_1) \ldots I(t_n) \rangle \in I(F) \\
\text{iff} \quad & \langle I(Ft_1 \ldots t_n) \rangle = 1
\end{aligned}
$$

Induction step for ∃

> Suppose $I(\exists xB(x)) = 1$. Then for some I° differing from I in at most its assignment to x, $I°(B(x)) = 1$. Let $I^\#$ be the same as I^* except possibly over its assignment to x, where $I^\#(x) = \phi(I°(x))$. It is easily verified that I° and $I^\#$ meet the conditions on I^1 and I^2 in the induction hypothesis, which then yields that $I^\#(B(x)) = 1$. Hence $I^*(\exists xB(x)) = 1$. The steps are obviously reversible.
>
> Other cases for induction are straightforward. ⊡

Theorem 1 ensures that given any assignment of truth-values to the sentences of L, induced by an interpretation I, there will be a quite different interpretation I^* of L based on a permutation of I's domain, which induces all the same truth-*values* on L's sentences, but makes quite different assignments to the names and predicates of the language.

Strong Permutation

A stronger permutation result will be that given an interpretation I of L, we can get a different interpretation I^* that departs from I over its assignments to names and predicates, whilst giving L's sentences the same truth-*conditions* (in the Putnam sense – the sentences of L coincide in truth-value not just at the actual world, but at every possible world, under the two interpretations). To state and prove this stronger result, we need some preliminary stage-setting:

By a world structure we mean a triple ⟨D,W,σ⟩, where D and W are non-empty sets (intuitively, think of W as the set of all possible worlds, of D as a very inclusive set of objects, containing each object which exists at any of the worlds in W), and σ is a function from W into the non-empty subsets of D (i.e., σ assigns a non-empty subset of objects to each world[38]).

Interpretations I are now assignments as follows: for each i and j, I assigns to the term t_i an element of the domain of w_j as its denotation relative to that world, that is, $I(t_i,w_j) \in \sigma(w_j)$.

And to each n-place F, I assigns, relative to each world w_j, a set of ordered n-tuples from the domain of w_j, that is, $I(F,w_j) \subseteq (\sigma(w_j))^n$.

Truth under I is now of course a relation between sentences of L and worlds, defined thus:

Atoms $I(Ft_1 \ldots t_n, w_j) = 1$ iff $\langle I(t_1,w_j) \ldots I(t_n,w_j) \rangle \in I(F,w_j)$

Molecules $I(\neg B.w_j) = 1$ iff $I(B,w_j) \neq 1$

$I(B \wedge C, w_j) = 1$ iff $I(B,w_j) = 1$ and $I(C,w_j) = 1$

$I(\exists xB(x), w_j) = 1$ iff there is an interpretation I° which differs from I at most in its assignment to x, such that $I^\circ(B(x), w_j) = 1$

Theorem 2 (strong permutation)

Let I be an interpretation of L. Let the ϕ_j be permutations[39] respectively of each of $\sigma(w_j)$ for all the $w_j \in W$. Let I* be any interpretation of L such that for all i and j, $I^*(t_i,w_j) = \phi_j[I(t_i,w_j)]$ and for every n-place F, $I^*(F, w_j) = \{\langle d_1, \ldots, d_n \rangle \mid \langle (\phi_j^{-1}(d_1), \ldots, \phi_j^{-1}(d_n) \rangle \in I(F, w_j)\}$. Then $I^*(A, w_j) = 1 \leftrightarrow I(A, w_j) = 1$

Proof is again by induction on the degree of A – the foregoing proof of *weak permutation* is readily adapted to show what's required for arbitrary w_j, simply by writing in w_j as an extra parameter as appropriate.

A is atomic, that is, $Ft_1 \ldots t_n$ for some n:

$$
\begin{aligned}
I^*(Ft_1,\ldots,t_n,w_j) = 1 \quad \text{iff} \quad & \langle I^*(t_1,w_j),\ldots,I^*(t_n,w_j) \rangle \in I^*(F,w_j) \\
\text{iff} \quad & \langle \phi_j(I(t_1,w_j)),\ldots,\phi_j(I(t_n,w_j)) \rangle \in I^*(F,w_j) \\
\text{iff} \quad & \langle \phi_j^{-1}(\phi_j(I(t_1,w_j))),\ldots,\phi_j^{-1}(\phi_j(I(t_n,w_j))) \rangle \in I(F,w_j) \\
\text{iff} \quad & \langle I(t_1,w_j),\ldots,I(t_n,w_j) \rangle \in I(F,w_j) \\
\text{iff} \quad & I(Ft_1,\ldots,t_n,w_j) = 1
\end{aligned}
$$

As before, the induction step is quite straightforward. Here, for illustration, is the case for $\wedge$:

Suppose $I(B \wedge C, w_j) = 1$. Then $I(B,w_j) = I(C,w_j) = 1$. By IH, $I^*(B,w_j) = I^*(C,w_j) = 1$. Hence $I^*(B \wedge C, w_j) = 1$. Steps obviously reversible.

Strengthening for Second-Order Languages

We extend our first-order language L by permitting binding of (first-level) predicate variables by the second-order existential quantifier ∃f – we use f,g, … as predicate variables. An interpretation of our second-order language L^2 will make assignments to them of entities of the same types as are assigned to predicate constants in the first-order case. 'true under I' is defined as for previous cases, except that we add a clause for the second-order quantifier:

$I(\exists fB(f))=1$ iff there is an interpretation I° which differs from I at most in its assignment to f, such that $I^\circ(B(f)) = 1$

With this addition, we can straightforwardly extend the weak and strong permutation results to the second-order case – all that is needed is an extra case in the induction, dealing with sentences in which the principal operator is second-order ∃. For the second-order extension of Theorem 1, this runs:

Induction step for second-order ∃

Suppose $I(\exists fB(f)) = 1$. Then for some I° differing from I in at most its assignment to f, $I°(B(f)) = 1$. Let $I^{\#}$ be the same as I^{*} except possibly over its assignment to f, where $I^{\#}(f) = \{\langle d_1,\ldots,d_n\rangle \in D^n \mid \langle \phi^{-1}(d_1),\ldots,\phi^{-1}(d_n)\rangle \in I°(f)\}$. Then by the induction hypothesis, $I^{\#}(B(f)) = 1$. Hence $I^{*}(\exists fB(f)) = 1$. The steps are obviously reversible.

Languages with Modal Operators

The addition of a modal operator, say □, to L (or L^2) permits the formation of complex sentences which are not truth-functions of their atomic constituents. That is, we can form sentences B with atomic constituents $A_1 \ldots A_k$ so that B's truth-value at a world w_j is not a function simply of the values of $A_1 \ldots A_k$ at w_j. B's truth-value at w_j is, rather, a function of the values of $A_1 \ldots A_k$ at the other worlds in W.

Does this prevent us from running the permutation argument? Well, it seems that it should *not* do so – just because, while a modal sentence's truth-value at a given world is not a function of the values of its atomic ingredients at *that* world, it is a function of their values at other worlds. But we know from *strong permutation* that we can jiggle the assignments to individual constants and predicates in such a way as to obtain an 'unintended' interpretation which agrees with the original interpretation on the truth-values of all the sentences of L (or L^2) at all possible worlds (so that they have the same truth-conditions, in Putnam's sense). It follows from this that adding □ to L (or L^2), with the usual clause to the effect that $I(\Box B, w_j) = 1$ iff $I(B, w_k) = 1$ for all w_k accessible from w_j, can make no essential difference to the situation. The essential point is this. Given an interpretation I which induces a *pattern* of truth-values on a sentence B across the possible worlds, we can construct a variant interpretation I^{*}, differing from I in its assignments to terms and predicates (and in case of L^2, predicate variables) at those worlds, but agreeing with I on the induced value of B at each world. And that is enough to ensure that I and I^{*} will not diverge over the truth-values of modal functions of B.

Notes

1 "Models and reality," in Putnam (1983, p. 13).

2 Putnam (1981, p. 49): cf. also "A defense of internal realism," in Putnam (1990a, p. 30).

3 The Twin Earth argument was first presented in Putnam's "The meaning of 'meaning,'" see especially Putnam (1975, pp. 223 ff.). An abbreviated statement of it is given in Putnam (1981, pp. 22–29). See also pp. 41–43 for the distinction between pure and impure mental states; and Chapter 8, A GUIDE TO NATURALIZING SEMANTICS.

4 By saying that an assignment of truth-values to sentences meets operational constraints, Putnam means, roughly speaking, that it accords with all the observational data that is available in principle. By theoretical constraints he means whatever further methodological constraints – including pragmatic considerations such as simplicity and economy – guide the optimum choice between theories which meet all operational constraints. Cf. "Models and reality," in Putnam (1983, pp. 3–6).

5 See Putnam's classic characterization of the 'internalist perspective' (1981, pp. 49 ff.).

6 Thus he writes:

> For an internalist like myself, the situation is quite different…. Signs do not intrinsically correspond to objects, independently of how those signs are employed … 'Objects' do not exist independently of conceptual schemes. *We* cut up the world into objects when we introduce one or another scheme of description. Since the objects *and* the signs are alike *internal* to the scheme of description, it is possible to say what matches what…. Indeed, it is trivial to say what any word refers to within the language the word belongs to, by using the word itself. What does 'rabbit' refer to? Why, to rabbits of course. (1981, p. 52)

See also "Models and reality," in Putnam (1983, p. 24).

7 This question has exercised some of Putnam's critics, e.g., Blackburn (1994, p. 27), but needlessly, if we are right.

8 See, e.g., remarks at pp. 25, 27, and 29.

9 Putnam (1981, p. 52). Cf. also:

> if the received view is correct, then we would have an elegant *account of how* intensions and extensions are fixed. [p. 32. our emphasis] One might say that … my 'mental representations' … *refer* to cathood … this may be true, but it just repeats that reference is fixed in one way rather than another. This is what we want to explain and not the explanation sought. [p. 37] To explain reference in terms of (impure) intention would be circular. And the problem of how *pure* mental states of intending, believing, etc., can … constitute reference is just what we have found so puzzling. [p. 43]

10 More about this matter below.

11 Cf. Putnam (1981, p. 34). Putnam's stipulation for (c)-worlds is a little odd – it would have sufficed to have 'cat' refer to cats and 'mat' refer to mats in this case, since all that's required is that 'A cat is on a mat' be false in (c)-worlds.

12 For formal details, see the Appendix.

13 That said, it's worth observing that, even if Putnam's project were to argue for the indeterminacy of reference *tout court*, it's not clear that the permutation argument would be vulnerable to the stated objection. For the proof of the permutability of reference – illustrations apart – is *entirely general*, and following it need involve consideration of no specific suppositions about the reference of particular expressions in the language: suppositions whose status might then be settled by stipulation. Someone – not Putnam – who wanted to harness the permutation argument to a general skepticism about reference *could* quite coherently carry its conclusion forward in the form of the counterfactual: if there were such a thing as determinate reference, it would not be recoverable from the truth-conditions of sentences. And indeed, the overall strategy of arguing for indeterminacy by establishing enough such counterfactuals, with a sufficient variety of consequents ('…, it would not be recoverable from speakers' intentions,' '…, it would not be recoverable from facts about causality,' etc.), is a perfectly coherent one. By the same token, though, the concern – for a supporter of Putnam – that the model-theoretic argument may fail stably to focus against metaphysical realism, dissolving instead into 'Putnam's Paradox,' is not so easily set aside.

14 See, for instance, Ian Hacking (1983, p. 105); though this may not be quite fair to Hacking, who in the relevant passage is mainly raising a doubt about the first-order formalizability, e.g., of physical theory, and is not really emphasizing the failure of the Lowenheim–Skolem Theorem at second order. Cf. Putnam's remarks in n. 11 of Putnam (1989, p. 230).

15 Permutation results for second-order languages and languages with the usual modal operators are outlined in the Appendix.

16 There are, however, reasons to qualify the force of this reservation, whose significance will emerge only when more has been done to explain how Putnam's argument can bear selectively on metaphysical realism. See §VII, and especially n. 31 below.

17 Hartry Field (1972). Field's view is discussed by Putnam (1981, pp. 45–46; 1978, pp. 14–17, 30–32, and 57–58).

18 A reason for thinking the tension merely apparent will anyway emerge in §VI below – see also n. 25.

19 Besides directing it at Field's in the passage quoted, Putnam (1983, p. 18) makes essentially the same move against Evans's (1973) version of the causal theory, and (1989, pp. 219–220) against Devitt's appeal to a causal theory (q.v. Devitt, 1983).

20 This claim appears to run counter to Putnam's own view, as expressed in "Model theory and the 'factuality' of semantics" (1989). He stresses there that his model-theoretic argument is directed against a limited target – *physicalistic* metaphysical realism. Certainly some of the argumentation rehearsed in that paper relies upon the assumption that the metaphysical realist aspires to a physicalist account of reality – including the circularity argument discussed above. Our point is that the 'just more theory' move is *not* subject to this limitation. A similar point is made by David Lewis (1984, pp. 232–233).

21 Something like this may well be the intended thrust of Putnam's complaint (1983, p. xi) that the causal realist "ignores his own epistemological position."

22 Putnam advances two quite distinct objections against the proposal. This is his first objection; we shall discuss the second in due course. Meanwhile, note that the first objection is to any identification of reference with a physicalistic relation, regardless of whether it is made in the interests of defending metaphysical realism.

23 Putnam (1989, p. 217). Putnam has 'requirement' where we have 'proposal.' The requirement to which he refers is presumably that if a relation R is to be the 'intended' reference relation, the supposition that R is the reference relation should yield an explanation of facts about our use of words.

24 A more detailed formulation of this argument is given in "Beyond historicism" (1983, pp. 290–298). We lack space to discuss it here, but it seems to us that it is vitiated by the same gratuitous assumption that anyone who proposes a 'theoretical identification' of an intentional notion – such as *explanation* or *reference* – is thereby debarred from using the notion in question in arguing for the identification. That this might be a reasonable restriction to impose on attempts at *analytic* reductions of intentional notions seems quite irrelevant.

25 Cf. "Models and reality" in Putnam (1983, p. 17). This bears on the interpretative question left dangling in §IV – it is clearly quite consistent with holding that a causal constraint needs to be met in many (or even all) cases of genuine reference to deny that a full constitutive account of reference may be given in purely causal terms.

26 Here is a relevant passage from "Model theory and the 'factuality' of semantics" at p. 219:

> if *E(T)* is the event of someone's using a token of a term *T*, then there is a good sense of 'causal connection' in which *every* event in the backward light-cone of *E(T)* is 'causally connected' to the event *E(T)*; but it will almost never be the case that the term *T*… *refers* to every event in the backward light-cone of *E(T)* (and it will typically be the case that the term does refer to things with which the token is *not* causally connected, e.g., future things).

27 "Models and reality" in Putnam (1983, p. 18). See Evans (1973, pp. 187–208) for his version of the theory. For some further discussion of this approach, see Chapter 35, REFERENCE AND NECESSITY, esp. §4.

28 Putnam would probably concede that the first difficulty may not be insuperable – cf. his acknowledgement that Evans has a proposal, to which he offers no objection – to deal with this problem: see the footnote on p. 18 of "Models and reality," in Putnam (1983). He does press the difficulty a little further, claiming that the distinction between causes and background conditions is inescapably interest-relative; but this shows at best that the relevant causal relations can't be singled out by appeal to that distinction, not that they can't be singled out at all.

29 Further objections, complementing those brought by Putnam (and those discussed in Chapter 8, A GUIDE TO NATURALIZING SEMANTICS), and including a forceful play with the holism of the mental, are developed by Paul Boghossian (1991).

30 Putnam, of course, is well aware of the possibility of this response to his argument, envisaging it explicitly (1989, p. 220); however, he does not regard acknowledging the primitiveness of reference

as a commitment to regarding it as 'simple and irreducible.' *Representation and Reality* is, in effect, an extended argument to the contrary.

31 The astute reader will note that if these considerations are indeed the key to the question of how Putnam's argument can tell selectively against metaphysical realism, then there actually is little force – in the resultant dialectical setting – in the reservation with which our discussion of the significance of the permutation argument concluded in §III. That reservation was, in effect, that while permutation-based reinterpretations of a language might be *consistent* with all data concerning the use of its sentences, they would be likely to be dominated by the preferred interpretation once appropriate constraints on the construction of interpretational theories, beyond adequacy to the linguistic data, are allowed their proper influence. But that, if correct, is a point about the methodology of interpretation – something which can be freely acknowledged from the internal realist point of view as conditioning the concept of truth that applies to ascriptions of reference and other semantic claims, but which takes us no closer to the *constitutive* account which the metaphysical realist needs of the nature of reference, conceived as a network of external relations of which methodologically superior interpretation is, at best, a means of discovery.

32 Recall the complaint which Putnam airs against Lewis's positive view, that it amounts to "saying that we-know-not-what fixes the reference relation we-know-not-how" (1989, p. 220).

33 So far as we are aware. Putnam does not himself explicitly employ the metaphor of 'slicing.' But it is common in discussion of his ideas and implicit in several of his own characterizations of internal realism. For example, "'Objects' do not exist independently of conceptual schemes. *We* cut up the world into objects when we introduce one or another scheme of description" (Putnam, 1981, p. 52). Of a piece with this are his frequent characterizations of external or metaphysical realism as involving – via its commitment to the idea that there is, whether we can discover it or not, just one true theory of the world – a belief that there is a 'ready-made world,' having an intrinsic or 'built-in' structure, comprising a 'fixed totality of mind-independent objects.' Cf., for example, Putnam (1983, p. 211; 1981, p. 49).

34 But an outright repudiation of the idea of sortal predetermination, even if not accompanied by a lurch into constructivist metaphor, would be in at least *prima facie* conflict with retention of the idea, of which Putnam himself has been a principal advocate, that the world encompasses various *natural kinds*. The apparent tension here runs parallel to that noted earlier, between Putnam's advocacy of an externalist account, in broadly causal terms, of how reference is 'fixed,' on the one hand, and on the other, his insistence that no progress can be made on the problem of explaining how reference can be determinate by appeal to causal relations between our words and appropriate bits of the world. So, unless the tension can be argued to be merely apparent, some qualification is needed. We cannot pursue this somewhat delicate issue here, and must content ourselves with one brief cautionary remark. Even supposing that the repudiation of sortal predetermination needs qualification to make space for belief in natural kinds, it would be a mistake, for at least two reasons, to think that this could be exploited to recover a metaphysically realist conception of determinate reference. First, the hypothesis that certain things instantiate a natural kind would, at best, serve to explain the *unity* of a class of things forming the reference or extension of a predicate as distinct from explaining what *constitutes* reference to that class. (This point may, we suspect, contain the germ of a resolution of the apparent tension – but that is a further issue.) Second, however precisely the envisaged qualification might run, it would be restricted in scope in a way which would, even prescinding from the previous point, preclude its yielding a fully general solution to the problem with which Putnam confronts the metaphysical realist. Crucially, we could expect no help with explaining how non-natural-kind terms can enjoy determinate reference. Essentially the same limitation vitiates David Lewis's proposal (1984, pp. 226–229) that some things, such as rabbits, are more eligible to be the referents of our words than others, such as undetached rabbit parts, and that rival schemes of reference may be ranked as better or worse to the extent that their assignments of referents respect 'nature's joints.' Indeed, the difficulty is not just that appeal to natural divisions could afford an at best partial solution to the general problem; it can be seen, on reflection, that it fails to accomplish even that much – the permutation

argument can just as well work to deliver perverse jigglings of perfectly *eligible* referents, and has no need for play with unnatural divisions at all.

35 From "Why there isn't a ready-made world" in Putnam (1983, p. 208).

36 Indeed, Putnam himself has recently shown signs of a cooling in his opposition to realism as Dummett conceives it (e.g., 1994, pp. 503, 510–511).

37 We are indebted to Philip Percival, and to colleagues who attended the Putnam conference in Utrecht in September 1994, especially Putnam himself.

38 The point of this complication is simply to avoid making the needlessly restrictive – and unrealistic – assumption that possible worlds do not differ in point of which objects they contain. In the special case where that assumption holds, we could dispense with the function σ, and need only consider a single permutation ϕ of the domain common to all possible worlds. This special case is, of course, covered by Theorem 2 as stated.

39 Each of the permutations ϕ_j could, of course, be defined to be the restriction to $\sigma(w_j)$ of a single permutation ϕ of the inclusive set D.

Postscript: Recent Work on Putnam's Model-Theoretic Argument

JUSSI HAUKIOJA

During the past 15–20 years, Putnam's model-theoretic argument has no longer been a hot and fashionable topic in philosophy. It has, however, secured its place as one of three central arguments in analytic philosophy where *referential indeterminacy* figures in a central role, the other two being Quine's argument for referential inscrutability (see Chapter 26, INDETERMINACY OF TRANSLATION), and Kripke's Wittgenstein's skeptical paradox about rules (see Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING). Nonetheless, interest in features particular to the model-theoretic argument, its proper interpretation, and its role in Putnam's argumentation as well as in anti-realist arguments in general, has by no means disappeared. A number of articles putting forward interesting new suggestions in these regards have come out, as well as two books (Taylor, 2006; Button, 2013) that build centrally on Putnam's argument, or argumentation directly inspired by it.

In this postscript, I want to highlight two strands in the recent discussions.[1] Both of these can be seen as attempts to bring new life to two ideas that had come under heavy criticism in the earlier debates: the 'just more theory' maneuver that Putnam employs as a part of the model-theoretic argument, and referential magnetism as a way of *responding* to Putnam's arguments.

1 Reconsidering the 'Just More Theory' Maneuver

In discussions of Putnam's model-theoretic argument, a near consensus seemed to have been reached in the 1990s that the 'just more theory' maneuver (henceforth the 'JMT maneuver') is question begging (cf. Hale and Wright, §V). It is one thing to say that, for example, causation singles out the intended interpretation for our theories, and another to say that *causation-talk* does that. The metaphysical realist who appeals to causation intends, of course, the former but not the latter. Therefore, to deny the realist the possibility to appeal to causal constraints in explaining word-world relations – including the word-world relations for terms such as 'causation' – is to beg the question. The JMT maneuver, according to this response, is based on a fairly elementary use-mention confusion.

Some commentators have recently expressed doubts about this consensus, and gone on to present reconstructions of the model-theoretic argument in an attempt to show that there is more to Putnam's maneuver than first meets the eye. A helpful starting point to this is in fact found already in some of Lewis's comments on Putnam (Lewis, 1984, p. 233). The JMT maneuver was clearly intended to work not just against causal constraints, but against *any* constraints that the metaphysical realist could come up with. But if the JMT maneuver were intended as a *completely* general one, we should expect it to work just as well against

"magical," non-naturalistic constraints as against naturalistic ones. But, since Putnam (mockingly) introduces a "magical theory of reference" as the metaphysical realist's only recourse, clearly he thought such a view would be immune to his argument. To be charitable to Putnam, we should at least try to see whether there is something specific to the metaphysical realist's position, and the constraints available to it, to make it vulnerable to the JMT maneuver.

Igor Douven (1999) and Tim Button (2013) have sought to reconstruct the model-theoretic argument in ways that define the intended target[2] of the argument more clearly, as a certain sort of meta-semantic naturalism.[3] According to meta-semantic naturalism, our theory of what singles out an intended interpretation for our words is an empirical theory, completely on a par with other scientific theories. Putnam is assuming that any metaphysical realist will be committed to meta-semantic naturalism, and it is *this* assumption that makes metaphysical realists vulnerable to the JMT maneuver. According to metaphysical realism, as defined by Putnam, an epistemically ideal theory may be false. Given meta-semantic naturalism, an epistemically ideal *meta-semantic* theory may be false: consequently the meta-semantic constraints are 'just more theory' *by the realist's own lights* (cf. Douven, 1999, pp. 488–490).[4]

Button (2013) presents the JMT maneuver as a dilemma posed to the metaphysical realist. Either the realist's proposed attempts to constrain reference have empirical content, or they do not. If they do, they are 'just more theory.' If they do not, then the realist is really invoking something like magic, and not living up to his or her own meta-philosophical ideals. Button goes on to argue, in considerable detail, that although the primary target of Putnam's model-theoretic arguments is a "bracketed empiricist" view – a version of logical positivism, or a direct descendant – the arguments can in fact be used against a variety of present-day varieties of metaphysical realism. The result, according to Button, is that metaphysical realists (or "external" realists, in Button's terminology) who accept that skeptical doubts about the external world make sense, cannot stop a slide from Cartesian skepticism to *Kantian* skepticism, questioning our very ability to represent an external world. However, Kantian skepticism is self-refuting, and we should thus reject the external realism that led to it.

2 Reference Magnetism

Another recent development in discussions of Putnam's model-theoretic argument – as well as of other arguments for meaning skepticism or referential indeterminacy – is the rise of *reference magnetism* as a respectable constraint on interpretation. The central idea, suggested by David Lewis[5] (1984), is that some properties are *reference magnets*, that is, that they are by their very nature more eligible to be the referents of our terms because they are *natural* properties, carving nature at its joints. Lewis's suggestion was long taken to be an *ad hoc* move (or even a piece of "occult metaphysics"; cf. Sider, 2011, p. 27), not to be taken seriously. In recent years, however, many theorists have sought to make the proposal seem more respectable.

The revival started (at least in print) with Weatherson (2003), where it was suggested that the classical analysis of knowledge could perhaps be defended against Gettier-style counter-examples by appealing to the *naturalness* of the category of justified true belief (or its superior naturalness relative to proposals that better respect our ordinary classifications). Williams (2007) and Sider (2011) present a defense of reference magnetism as a

general principle in meta-semantics, attempting to deflect charges of *ad hoc*-ness by deriving it from general doctrines about theoretical virtue. Williams and Sider argue that reference is an explanatory notion, and explanatory properties and relations should, in general, be cast in joint-carving terms: therefore, we have good reason to expect referential relations to be natural (or at least reasonably so).

There are two potential problems with this suggestion. First, it is one thing to say that the *reference relation* should carve nature at its joints, and quite another to say that the properties *connected to our terms* via the reference relation do so. The former may follow from general principles about explanatory virtue, but the reference magnetist is not putting forward the former claim, but rather the latter. And it is not obvious at all why the former should entail, or even give justification, for the latter: why should a joint-carving reference relation relate our terms to natural, rather than gerrymandered properties?[6]

Second, even if we agree that reference is an explanatory notion in semantics, a lot will turn on exactly *which explanatory projects* we expect referential relations to play a central role in. If, as seems plausible, referential relations are centrally involved in the explanation of successful linguistic communication, then it is by no means obvious that reference magnetism adds to the explanatory power of our theories. An example by Schwartz nicely illustrates the second problem: "Suppose a sentence S is systematically used to communicate that a certain state of affairs p obtains: speakers try to utter S if and only if p obtains, hearers take utterances of S as evidence for p, and so on. If magnetism is true, then it is a live possibility that, unbeknownst to everyone, S actually means not p but q, because q concerns objectively more natural properties" (Schwartz, 2014, p. 31).[7]

* * *

It remains to be seen how damaging the new reinterpretations of the model-theoretic argument, presented by Douven and Button, are against present-day versions of metaphysical realism. If they *do* work, then realists will have to renounce their meta-semantic naturalism and admit that meta-semantics is *not* an ordinary empirical enterprise, and try to make this concession somehow consonant with their overall metaphysical realist view.[8] The recourse to reference magnetism can be seen as one way of trying to accomplish this: to say that the choice between empirically equivalent interpretations of the total theory is to be decided by comparisons of relative naturalness is already to admit that the meta-semantics is not determined by empirically available evidence. But there is no reason to think that reference magnetism is the only way of doing this. At the very least, a robustly realist overall position in metaphysics does not seem to depend on a naturalistic conception of meta-semantics – nor is it immediately obvious that a metaphysical realist view as characterized by Putnam, insisting that even empirically ideal theories may be false, could not be combined with a non-naturalist conception of meta-semantics.

Notes

1 Two other strands, which will not be presented in detail here, are Bays's (2001) criticism of Putnam's use of model theory, and Chambers's (2000) claim that Putnam's argument is simply unsound. For criticism and discussion of Bays see Bellotti (2005), Bays (2007), Button (2011); for criticism and discussion of Chambers see Haukioja (2001), Kroon (2001), Chambers (2001).

2 Or rather, especially in Button's case, the proper target of a Putnam-style model-theoretic argument.

3 An earlier (re)interpretation of the model-theoretic argument that is in many ways similar was put forward by Zalabardo (1998): here, the aim of the argument is to show that if the metaphysical realist's conception of how referential facts are determined is right, we would not be able to grasp those very facts.

4 If this is the right way of construing the target of the argument, we can also see the relevant difference between Putnam's argument and Bays's (2008) "astronomical" argument (which Bays claims to be structurally similar to Putnam's): the crucial premise in Putnam's argument, stating that nothing but theoretical or operational constraints can single out the intended interpretation, is a part of meta-semantic naturalism, which Putnam uses as a premise in his *reductio*. The corresponding premise in Bays's "astronomical" argument is not a part of any (sensible) philosophical world view.

5 Schwartz (2014) argues, persuasively, that in fact reference magnetism was not a part of Lewis's account of language (nor was the global descriptivism that he, in responding to Putnam's model-theoretic argument, suggested should be enhanced by reference magnetism), although the naturalness of properties did play a role in blocking unintended interpretations in his theory of mental content.

6 Sider (2011, pp. 28–29) discusses the problem briefly, but concludes, for reasons that remain somewhat unclear, that the problem will not be a serious one if the reference relation is merely "reasonably" rather than "perfectly" joint-carving.

7 For further argument against reference magnetism, along similar lines, see David Chalmers's "Twentieth excursus: reference magnets and the grounds of Intentionality." http://consc.net/books/ctw/excursus20.pdf (accessed October 6, 2016).

8 Another option will, of course, be to reject metaphysical realism. But our problems do not simply disappear if we become anti-realists. Button, for example, finds anti-realism (as well as Putnam's "internal" realism) just as unacceptable as "external" realism, recommending that we, in the end, should steer a middle course between "external" and "internal" realism.

Sorites

MARK SAINSBURY AND TIMOTHY WILLIAMSON

1 The Early History

The logician Eubulides of Miletus, a contemporary of Aristotle, was famous for seven puzzles. One was the Liar: If a man says that he is lying, is he telling the truth? Another was the Hooded Man: How can you know your brother when you do not know that hooded man, who is in fact your brother? There were also the Bald Man and the Heap. In antiquity they were usually formulated as series of questions. Does one grain of wheat make a heap? Do two grains of wheat make a heap? Do 10,000 grains of wheat make a heap? If you admit that one grain does not make a heap, and are unwilling to make a fuss about the addition of any single grain, you are eventually forced to admit that 10,000 grains do not make a heap. Is a man with one hair on his head bald? Is a man with two hairs on his head bald? Is a man with 10,000 hairs on his head bald? If you admit that a man with one hair is bald, and are unwilling to make a fuss about the addition of any single hair, you are eventually forced to admit that a man with 10,000 hairs is bald. The standard ancient terms for the Heap and the Bald Man were "sorites" (from "soros," a heap) and "phalakros," respectively. Later, "sorites" was used for all such puzzles. They were also known as little-by-little arguments.[1]

Many philosophical doctrines have been suggested as the target Eubulides intended his Heap and Bald Man to destroy: the coherence of empirical concepts, the law of non-contradiction, the Law of Excluded Middle, pluralism, Aristotle's theory of infinity or of the mean. The evidence gives little support to any of these suggestions. Eubulides is indeed said to have attacked Aristotle, but in slanderous terms; the sources do not connect the dispute with any of the puzzles. Aristotle betrays no clear awareness of sorites reasoning in any of his extant works. Some later commentators did consider its use against Aristotle's theory of the mean, but without suggesting that either Eubulides or Aristotle had done so. Eubulides's interests were described as purely logical; if he had a specific target in mind, it is likely to have been a logical one.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

Sorites puzzles became a standard weapon of Skeptics in their attacks on Stoic philosophy. A Skeptic does not feel obliged to answer any of the sorites questions; he can simply plead ignorance. If a Stoic is obliged to answer each question "Yes" or "No," he will find himself in an embarrassing position. An obvious focus for Skeptical attack was the Stoic theory of knowledge. It was based on cognitive impressions, which represent real objects with complete accuracy and reliability (compare Descartes's clear and distinct ideas). The Skeptics constructed sorites series from cognitive to non-cognitive impressions, replacing each impression by a virtually indistinguishable one, and took themselves to have undermined Stoic claims to knowledge. Stoic defenses against these attacks were mustered by Chrysippus (*c.*280–*c.*207 BCE), the man with the best claim to have initiated propositional logic.

The Stoics firmly accepted the principle of bivalence: every proposition is either true or false. Chrysippus "strained every nerve" to persuade people of it. For any proposition *P* there is one right answer to the question "*P*?" "Yes" or "No"; for any sequence of propositions P_1, …, P_n there is one sequence of right answers to the questions "P_1?" …, "P_n?" The Stoics used "Are *i* few?" as the schematic form of the *i*th sorites question; thus the right answers to the first and last questions are "Yes" and "No" respectively, and there is a last question, "Are *i* few?" rightly answerable "Yes," immediately followed by a first question, "Are *i* + 1 few?" rightly answerable "No": *i* are few and *i* + 1 are not few; *i* is a cut-off point for fewness.

The Stoics distinguished between sentences and the propositions they are used to assert. The argument from bivalence to the existence of a cut-off point assumes that the sentences "One is few," …, "10,000 are few" express propositions. However, someone who utters "*i* are few" with the sense "A man with *i* hairs on his head is bald" does assert something, which on the Stoic view requires the sentence to express a proposition. The assumption gave no escape from the argument for a cut-off point. Indeed, there is independent evidence that the Stoics accepted the conclusion of the argument. In other cases which look susceptible to sorites reasoning they insisted on cut-off points; for example, they denied that there are degrees of virtue, holding that one is either vicious or perfectly virtuous. An analogy was drawn with a drowning man as he rises to the surface; he is coming closer to not drowning, but he is not drowning to a lesser degree until he breaks the surface, when he is suddenly not drowning at all. Moreover, in rebutting the sorites argument against cognitive impressions, Chrysippus dealt explicitly with the case "when the last cognitive impression lies next to the first non-cognitive one": cognitiveness has a cut-off point. The Stoics were prepared to apply bivalence to sorites reasoning and swallow the consequences: any difficulty in answering the sorites questions must come from our ignorance of the right answers, not their non-existence. The puzzle is an epistemological one.

One might answer the questions "Is one few?" … "Are *i* few?" "Yes," and the questions "Are *i* + 1 few?" … "Are 10,000 few?" "No": but one would be guessing. No one has such knowledge of cut-off points; no one knows both that *i* are few and that *i* + 1 are not few. Such a pattern of answers is forbidden by the principle that one should give an answer only if one knows it to be correct. The wise man, the Stoic ideal, conformed to that principle. Since he was infallible rather than omniscient, he would sometimes suspend judgment. The Stoics did not claim to be wise men, still less to be omniscient; they readily admitted that they did not know whether the number of stars was odd or even and that they could not distinguish between very similar hairs or grains (the examples are ancient). Nevertheless, the aim was to avoid error by withholding assent from what one did not know.[2] The Stoic who did not know enough to be wise should suspend judgment more often than the wise

man. That fits Chrysippus's recommended response to the sorites. At some point in the interrogation one should fall silent.

If sorites questions puzzled the Stoic simply because he did not always know whether to answer "Yes" or "No," like the question about the number of stars, he could confidently face the interrogation armed only with the three possible answers "Yes," "No," and "I don't know." If he knew *i* to be few he would answer "Yes"; if he knew *i* not to be few he would answer "No"; in every other case he would answer "I don't know." Why should an honest admission of ignorance not completely dissolve the puzzle?

However, Chrysippus did not say that one should admit ignorance; he said that one should fall silent. Under interrogation, saying "I don't know" is quite a different policy from saying nothing. The former but not the latter denies knowledge. This undermines the argument that the Stoic could answer each question "Yes," "No," or "I don't know."

The Stoic is supposed to say only what he knows to be correct. "I don't know" in answer to "Are *i* few?" is tantamount to the assertion "I don't know that *i* are few and I don't know that *i* are not few," just as "Yes" is tantamount to "*i* are few" and "No" to "*i* are not few." Thus the Stoic is supposed to answer "I don't know" only if he *knows* that he doesn't know whether *i* are few. The "Yes"/"No"/"Don't know" strategy requires the Stoic to answer "I don't know" whenever he doesn't know. It is therefore available, on Stoic terms, only if whenever one doesn't know whether *i* are few, one knows that one doesn't know whether *i* are few. For simplicity, one may be assumed to know a proposition just in case it is clear, where the logical consequences of what is clear are themselves clear. The prerequisite for the "Yes"/"No"/"Don't know" strategy is then that if *i* are neither clearly few nor clearly not few, *i* are clearly neither clearly few nor clearly not few. This is equivalent on Stoic terms to a pair of simpler principles:

(1a) If *i* are not clearly few, *i* are clearly not clearly few.
(1b) If *i* are not clearly not few, *i* are clearly not clearly not few.

Principles (1a) and (1b) are simply the relevant instances of the "S5" principle for clarity: if something is not clearly so, it is clearly not clearly so. Thus the "Yes"/"No"/"Don't know" strategy is available only if the S5 principle applies. However, the S5 principle is incorrect for clarity in such cases, for clear fewness is as sorites-susceptible as fewness. One is clearly few; 10,000 are not clearly few. By Stoic logic, there is a cut-off point for clear fewness: for some i, $i - 1$ are clearly few and i are not clearly few. Where that point comes is no clearer for clear fewness than for fewness. It is very slightly clearer that $i - 1$ are few than that i are few. But i are too close to being clearly few to be *clearly* not clearly few. One cannot reliably judge whether i are clearly few. In particular, one cannot answer the question "Are *i* clearly few?" just by following the policy: if you hesitate to say "Yes," say "No." If that policy worked, one would unhesitatingly judge that *i* were clearly few if and only if *i* were clearly few; whatever one thought was right would be right. But unless one is reasonably cautious, one will sometimes unhesitatingly judge that *i* are clearly few when they are not in fact clearly few (or even few). Most of us say silly things from time to time. On the other hand, if one is reasonably cautious, one will sometimes hesitate over what turns out to be genuinely clear, for fear of a hidden catch. Principle (1a) is false for some *i*. Principle (1b) fails similarly. Silence is the best policy.

When should the Stoic fall silent? Chrysippus seems to have advised that one should fall silent *before* the end of the clear cases. Stoic constraints may imply that one should

sometimes give no answer to the sorites question "Are *i* few?" even though *i* are clearly few. If one answers "Yes" whenever that answer is clearly correct, on Stoic assumptions one stops answering "Yes" either when it ceases to be clearly correct or later. In the former case one has located the cut-off point for clarity with perfect accuracy; in the latter one has violated the constraint that all one's answers should be clearly correct. Given the failure of the S5 principle for clarity, one cannot reliably locate the cut-off point for clarity with perfect accuracy; thus one will reliably satisfy the constraint that one's answers should be clearly correct only if one stops answering "Yes" before it has ceased to be the clearly correct answer. One must undershoot in order to avoid the risk of overshooting.

The point generalizes. One would like to satisfy two conditions:

(2a) If "Yes" is a good answer, say "Yes."
(2b) If "Yes" isn't a good answer, don't say "Yes."

The goodness of an answer is some truth-related property of it, and does not simply consist in its being given. There is play between the antecedents and consequents of (2a) and (2b); in an imperfect world they will sometimes come apart. In such a case, one either fails to say "Yes" when "Yes" is a good answer, violating (2a), or says "Yes" when "Yes" is not a good answer, violating (2b). If one regards violations of (2a) and (2b) as equally serious, one may simply aim to say "Yes" when and only when it is a good answer. Other things being equal, one's misses are as likely to fall on one side of the target as on the other, and no matter. But one might regard a violation of (2b) as worse than a violation of (2a); one would rather commit an error of omission by not saying "Yes" when it is a good answer than one of commission by saying "Yes" when it is not a good answer. For example, one might prefer failing to make true or warranted statements to making false or unwarranted ones, and follow a policy of saying nothing when in doubt. One decreases the risk of more serious violations by increasing the risk of less serious ones. At the limit, the price of never violating (2b) is sometimes violating (2a). That is the choice the Stoic makes in falling silent before the end of the clear cases, where clarity is goodness. It was worse to say "Yes" in an unclear case than not to say it in a clear one. Those who take the opposite view should fall silent after the end of the clear cases. The Chrysippan strategy can be seen as resulting from two levels of precaution. At the first level, goodness in (2a) and (2b) is simply truth. The Stoics were not alone in holding it to be worse to give a false answer than to fail to give a true one. For truth, (2a) rather than (2b) is to be violated. This preference motivates the constraint that one should give an answer only if it is clear. But then clarity takes on a life of its own as a cognitive end, and again the Stoic takes the cautious option. Condition (2a) rather than (2b) is to be violated for clarity too.

The Skeptics were not satisfied with Chrysippus's silence; it was most notably attacked half a century after his death by Carneades. "For all I care you can snore, not just become quiescent. But what's the point? In time there'll be someone to wake you up and question you in the same fashion." Chrysippus was dialectically no better off than he would have been had he fallen asleep, and Carneades's attitude was that of a chess player with what he takes to be a winning strategy, whose opponent simply refuses to make a move (in a game without time limits).

Suspension of judgment was the Skeptical attitude, and Carneades fastened on the extent to which Chrysippus's strategy allowed it to spread. If Chrysippus suspended judgment in

clear cases, on what basis did he object to the Skeptic's suspension of judgment? The question does not reduce the strategy to immediate incoherence, for some sort of reply is open to Chrysippus: do not suspend judgment when the case is clearly clear. Nevertheless, the Stoics were in a very delicate position. Their epistemological caution enlarged the concessions to Skepticism that their bivalent semantics forced them to make under sorites questioning. The concessions did not amount to surrender, for cases remained in which they could still claim knowledge; but these cases were marked off by a disputed no-man's-land rather than a compelling principle.

So far, the Heap and the Bald Man have been presented, as they usually were in antiquity, as series of questions, not as arguments with premises and conclusions. Yet one speaks of them as paradoxes, and a paradox may be defined as an apparently valid argument with apparently true premises and an apparently false conclusion. In argument form, the sorites goes like this:

Premise 1	1 is few
Premise 2	If 1 is few then 2 are few
Premise 3	If 2 are few then 3 are few
…	
Premise 10, 000	If 9,999 are few then 10,000 are few
Conclusion	10,000 are few

The argument appears to be valid; if its premises are true, its conclusion will be true too. The relevant rule of inference is *modus ponens* (MP), which allows one to infer *Q* from *P* and "If *P* then *Q*"; its validity is hard to challenge. By MP, "1 is few" and "If 1 is few then 2 are few" entail "2 are few." In the same way, "2 are few" and "If 2 are few then 3 are few" entail "3 are few." After 9,999 applications of MP, one reaches the conclusion "10,000 are few." The premise "1 is few" is apparently true and the conclusion "10,000 are few" apparently false. The gradualness of the sorites series makes each of the conditional premises appear true. Thus the apparently valid argument has apparently true premises and an apparently false conclusion. At least one of these appearances is misleading, for the conclusion cannot be both true and false.

The argument is valid by the standards of orthodox modern logic. It is also valid by the standards of Stoic logic. Two logical principles are at stake. One is MP; it was the first indemonstrable (primitive) form of argument in Stoic logic: "If the first, then the second; but the first; therefore the second." The other is the "Cut" principle that valid arguments can be chained together: thus the valid argument from "1 is few" and "If 1 is few then 2 are few" to "2 are few" can be chained together with the valid argument from "2 are few" and "If 2 are few then 3 are few" to "3 are few," giving a valid argument from "1 is few," "If 1 is few then 2 are few" and "If 2 are few then 3 are few" to "3 are few." The relevant form of Cut was the third Stoic rule for the analysis of complex arguments: "If from two propositions a third is deduced and there are propositions from which one of the premises may be deduced, then the other premise together with these propositions will yield the conclusion."

On Stoic terms, the argument is valid, its first premise true and its conclusion false. Thus not all the conditional premises are true. By the Stoic principle of bivalence, at least one of them is false, despite appearances. At this point there is a complication. The truth and falsity conditions of conditionals were the subject of a fierce controversy that went back to Diodorus and his contemporary, Philo, and was taken up by the Stoics. Philo treated the

conditional "If *P* then *Q*" as a truth-function of its components equivalent to "Not: *P* and not Q." In contrast, Diodorus held "If *P* then *Q*" to be at least as strong as "Not ever: *P* and not Q." Chrysippus went still further; for him, a conditional is true if and only if its antecedent is incompatible with the negation of its consequent. Thus "If *P* then *Q*" is equivalent to "Not possible: *P* and not Q." In modern terms, Philo's conditional is material implication, Chrysippus's is strict implication. Later Stoics tended to follow Chrysippus.

In the sorites argument, some conditional premise "If *i* are few then *i* + 1 are few" is supposed to be false. If the conditional is Chrysippan, it is false if and only if "*i* are few" is compatible with "*i* + 1 are not few." However, this conclusion looks banal; who thought them incompatible? Chrysippus might cheerfully allow that all the conditional premises, so taken, are false. To know the falsity of such a conditional is not to identify a cut-off point; it is merely to know that a certain point is not debarred from being the cut-off. For some modern philosophers, sorites puzzles arise because vague concepts are subject to tolerance principles which do rule out the possibility of cut-off points and "*i* are few" does threaten to be incompatible with "*i* + 1 are not few," making the Chrysippan conditional "If *i* are few then *i* + 1 are few" true.[3] But the Stoics did not take that view, and may not have regarded the argument with Chrysippan conditional premises as genuinely challenging.

The most challenging form of the sorites argument uses the Philonian conditional, for it is the weakest connective to obey MP, which is to say that it is the weakest conditional. If the conditional premises are true on any reading, they are true on this one. Since it was not the standard reading of the conditional, the Stoics had to formulate the premises explicitly as negated conjunctions to confront the argument in its most telling form. Just that was done in standard Stoic accounts.

Once the explicit conditional has been eliminated, MP can no longer be used, but Stoic logic still obliges. The sorites argument with negated conjunctions is valid, its first premise is true and its conclusion false. Thus some premise of the form "Not: *i* are few and *i* + 1 are not few" is false. By the falsity condition for the Philonian conditional, *i* are few and *i* + 1 are not few. Thus *i* is a sharp cut-off point for fewness. Since one cannot identify such a point, one is in no position to deny any of the premises; one can only suspend judgment. The challenge "Which premise is false?" is unfair, for one may be unable to find out even though one knows that at least one premise is false.

What is gained by presenting the sorites as an argument with premises and conclusion? Its logical structure was never the point at issue, for the argument is formally valid according to those whom it threatens, the Stoics, who used arguments with that structure themselves. As for the Skeptics, they could suspend judgment on its logical status; it was enough for their purposes that their opponents took such arguments to be valid. The logical structure provides a convenient way of laying out the problem, but so far nothing more.

It is tempting to argue for a dialectical structure behind the logical façade. One point is that the use of conditionals in the sorites argument is a distraction, since the sorites interrogation shows that one can set the puzzle going in a language whose only resources are "Yes," "No," and simple sentences (without logical connectives such as "if," "and," and "not") in the interrogative mood. Moreover, the argument has been persuasive so far not because its premises commanded assent, but because they forbade dissent. The problem was not that one could say "Not: *i* are few and *i* + 1 are not few," but that one could not say "*i* are few and *i* + 1 are not few." One is not presumed to believe the premises of the sorites argument. The point of the questions is to force one to take up attitudes for or against the individual propositions, for any pattern of such attitudes leads one into trouble. Since the premises of

the sorites argument seem compelling only when one is interrogated on their components, the question form takes primacy.

The situation is transformed if the premises of the sorites argument can be given positive support. If they can, the argument form takes primacy: the question form leaves too much unsaid. What is more, Chrysippan silence is no longer an adequate response, for it does not undermine the positive support for the premises. Awareness of the need to provide that support is shown by Galen (AD *c*.129–*c*.199): "I know of nothing worse and more absurd than that the being and non-being of a heap is determined by a grain of corn." Chrysippus could not have suspended judgment on the general claim that one grain does not make the difference between a heap and a non-heap. He must deny it, for it contradicts the existence even of an unknown cut-off point. For him, the addition of one grain can turn a non-heap into a heap.

Galen's interest in sorites puzzles was connected with a long-running dispute between Empiricist and Dogmatic (one might say "Rationalist") Doctors. The Empiricist Doctors based their medical knowledge on inductive inferences, holding it to be reliable only if derived from sufficiently many observations; their opponents applied sorites reasoning against the notion "sufficiently many." The Empiricist Doctors replied that the argument proved too much; if it destroyed the notion of sufficiently many observations, it would by parity of reasoning destroy much of the common sense on which all must rely. They gave the examples of a mountain, strong love, a row, a strong wind, a city, a wave, the open sea, a flock of sheep and a herd of cattle, the nation and the crowd, boyhood and adolescence, the seasons: none would exist if sorites reasoning were to be trusted. The Empiricist Doctors could reasonably claim to know that sorites arguments were unsound, without claiming to know exactly where the flaw lay. Even Chrysippus could not say which premise in negated conjunction form was false.

It was known that for every sorites series which proceeded by adding (as Eubulides's original series seem to have done), a reverse sorites series proceeded by subtracting. Thus examples tend to come in pairs of opposites: rich and poor, famous and obscure, many and few, great and small, long and short, broad and narrow. The awareness of reversibility no doubt helped to check the tendency to think of a sorites puzzle as showing its conclusion to be strange but true, for the conclusion of one sorites argument contradicts the first premise of the reverse argument.

There are also signs of a rather different Empiricist point. The sorites questioner is compared to someone who asks a shoemaker what last will shoe everyone: the question has no answer, for different feet require different lasts. The idea may be that the required number of observations depends on the circumstances of the particular case. There is no general answer to the question, "Are 50 observations enough?" The point has been repeated by modern philosophers, and is correct as far as it goes, but that is not very far; for the questions can be asked about a particular case, and the Empiricist still cannot plausibly claim to know all the answers. The same goes for heaps. Fifty grains may make a heap in one arrangement and not in another; but in any particular process of piling up grains one by one there will be a point at which the right answer to the question "Is this a heap?" is unknown.

As logic declined in later antiquity, so did interest in sorites puzzles. They formed no part of the medieval logic curriculum, perhaps because of their absence from the works of Aristotle. Their revival had to wait for what is usually seen as the corruption of logic in the Renaissance. Lorenzo Valla (1407–1457) was one of the chief instigators of a shift from the formal rigor of scholastic logic to the more literary pursuit of humanist dialectic, and his

preference for Cicero over Aristotle led him to Cicero's account of sorites arguments. Valla rejected them, on the grounds that even one grain makes some difference, in his original treatment of multiple syllogisms. Unfortunately, later writers did not develop his suggestions. Sorites puzzles were known as curiosities. Logic textbooks used the term "sorites" for all syllogisms with more than two premises. Stoic arguments do not count as multiple syllogisms, for they turn on the logic of propositional connectives such as "if" rather than quantifiers such as "all" and "some." The analogy with the original sense of "sorites" lies in the repetition of steps, but the textbooks did not associate sorites syllogisms with paradoxes in any way.

Leibniz knew of the Heap and the Bald Man. For him, unlike the Stoics, the ideas of heap and baldness exemplify indeterminacy: their limits, like those of color ideas, have not been fixed. A borderline case is a matter of opinion, different opinions being equally good.[4] In one respect, Leibniz shared the view which has dominated twentieth-century discussions: that the ignorance associated with vagueness is not a matter merely of not knowing where the cut-off lies, but of there being nothing to know.

2 Recent Approaches

In the first half of the twentieth century sorites paradoxes aroused little interest. An exception is Russell's 1923 article. He takes the paradoxes seriously, and responds as follows:

> [if a hairy man goes bald] it is argued [that] there must have been one hair the loss of which converted him into a bald man. This, of course, is absurd …. there are men of whom it is not true to say they must either be bald or not bald. The law of excluded middle is true when precise symbols are employed, but it is not true when symbols are vague. (pp. 85–86)[5]

More recently, sorites puzzles have been discussed in the form of apparently sound arguments with apparently false conclusions, and philosophers such as Dummett and Wright have advanced grounds for the premises. As noted earlier, this renders Chrysippan silence by itself an insufficient response: the grounds for the premises must be rebutted.

The recent tradition has largely ignored the epistemic view of vagueness, assuming, by contrast, that borderline cases, initially characterized as those where we do not know what to say in answer to a sorites question, are cases in which there is no fact of the matter to be known. Such a view cannot avoid commitment to indeterminacy at the semantic level: for some sentences there is no fact of the matter whether they are true, and for some predicates and some objects, no fact of the matter whether the former apply, or fail to apply, to the latter. So we will refer to the "no fact of the matter" conception of vagueness as the "semantic" conception. (The conception may be coupled with different views about the ontological status of the absence of determinate fact. On one view, once the semantics have been properly formulated, there is nothing more to be said; on another view, the semantic indeterminacy reflects some real indeterminacy in the non-linguistic world itself.)

Developing the semantic conception of vagueness requires abandoning classical semantics or logic. In the context of the rise of formal methods dating from the middle of the last century, it is not surprising that a number of non-classical systems have been designed to accommodate vagueness, semantically conceived; and we will shortly survey some of these theories.

First, however, we present three schemata of sorites-paradoxical arguments (§2.1). Second, we examine arguments which have been given for the truth of their premises or the falsehood of their conclusions (§2.2). Third, we review some formal treatments of vagueness (§2.3); and fourth, we remind the reader of the attractions of the epistemic view of vagueness, but also indicate a potential source of difficulty for the view (§2.4).

2.1 Three Forms of Paradoxical Arguments

With no sand you cannot make a heap of sand; and if you have just one more grain, you cannot make a heap from what is not a heap. Hence there are no heaps of sand. The argument could be schematized so as to fit the standard pattern of argument by mathematical induction, with quantifiers ranging over the natural numbers and "x'" abbreviating "$x + 1$":

$$\text{(A)}\quad \frac{\varphi(0) \quad \forall x(\varphi x \rightarrow \varphi x') \quad \text{(QP)}}{\forall x \varphi x}$$

We refer to the quantified premise as QP. This schema yields the heap paradox itself if we replace "φx" by "a collection of x grains cannot make a heap no matter how it is arranged."

Imagine a painted wall hundreds of yards or hundreds of miles long. The left-hand region is clearly painted red, but there is a subtle gradation of shades, and the right-hand region is clearly yellow. The strip is covered by a small double window which exposes only a small section of the wall at any one time. It is moved progressively rightwards, in such a way that at each move after the initial position the left-hand segment of the window exposes just the area that was in the previous position exposed by the right-hand segment. The window is so small relative to the strip that in no position can you tell any difference in color between what the two segments expose. After each move, you are asked to say whether what you see in the right-hand segment of the window is red. You must certainly answer "Yes" at first. At each subsequent move you can tell no difference between a region you have already called red and the one for which the new question arises. It seems that you must after every move call the next region red, and thus, absurdly, find yourself calling a clearly yellow region red.

This form of sorites can also be molded to schema (A). One could stipulate that the successive positions of the right-hand segment of the window are numbered upwards from 0, and replace "φ" by "… numbers a red region." Equally, and with no difference of substance, we can regard the numerals as simply naming the successive regions, and replace "φ" simply by "red."

One does not need to argue by mathematical induction to have sorites paradoxes. We could, as we saw in §1 (p. 738) write out, say, 10,000 singular conditionals instead of QP, and use *modus ponens* to derive the absurd result that a collection of 10,000 grains, however arranged, cannot make a heap. The schema is:

$$\text{(B)}\quad \frac{\varphi(0) \quad \varphi(0) \rightarrow \varphi(1) \quad \ldots \quad \varphi(9{,}999) \rightarrow \varphi(10{,}000)}{\varphi(10{,}000)}$$

We do not need to use either conditionals or quantifiers in the premises, for example:[6]

$$\begin{array}{ll} (\mathrm{C}) & \varphi(0) \\ & \neg\varphi(10{,}000) \\ \hline & \exists x(\varphi x \,\&\, \neg\varphi x') \quad (\mathrm{QC}) \end{array}$$

An instance might be: A man with 0 hairs on his head is bald, and a man with 10,000 hairs on his head is not; therefore there is some number of hairs such that a man with that number of hairs is bald and a man with one more hair is not. The supposed absurdity is the derivation of the existence of a sharp boundary, represented by the quantified conclusion (QC).

In all cases, the arguments appear to be sound, yet they have what appear to be false conclusions.

The availability of these different formulations, and others we have not mentioned, puts constraints on what sort of solution is acceptable. A reasonable initial hope is that there is a single correct approach to all forms of sorites. If this hope can be fulfilled, it would be no good merely to argue, with schema (A) in mind, that the principle of mathematical induction does not hold for vague predicates, for this would not touch sorites arguments exemplifying schemata (B) and (C).[7] Equally, it would not do to suppose that one need only point out that by adopting an intuitionistic logic, one can deny the QP of (A) without thereby being committed to the seemingly unacceptable classical equivalent of its negation, $\exists x(\varphi x \,\&\, \neg\, \varphi x')$ (cf. Putnam, 1983; Read and Wright, 1985; Putnam, 1985); for paradoxical arguments modeled on the other schemata are not touched by this point.

2.2 Arguments for the Premises or against the Conclusions

We will consider two kinds of argument: (a) from the nature of observation; and (b) from the nature of vagueness.

2.2.1 Observational Predicates

Perhaps one can always apply "red" or at least "looks red" correctly, under suitable circumstances, just by looking. If so, then if under such circumstances two things look the same, and the predicate is true of one, it is true of the other. With "red" or "looks red" inserted as before into the replacement for "φ," this line of thought justifies the conditional premises in schema (B), the QP in (A), and the negation of the conclusion of (C) (that is, not-QC). The conditionals would be justified by the fact that, given that adjacent regions on the wall look the same, the truth of an antecedent of the form "x is (or looks) red" would be enough for the truth of a consequent corresponding to "x' is (or looks) red." The QP of (A) would be justified by the fact that, given the same feature of the wall, "red" (or "looks red") must apply to both or neither of adjacent regions; and this would also establish the falsehood of the QC of (C).

Since the truth-values of the atomic premises and conclusions are uncontroversial, this would take care of all that is controversial in showing that the arguments have true premises and false conclusions. If one takes this result at face value one must regard classical logic, and any other logic upon which arguments molded on any of the schemata (A)–(C) are valid, as incorrect.

"Red" (or "looks red") is meant to be an example of a more general phenomenon: the "observationality" of certain predicates. Dummett suggests that an observational predicate is one "whose application is determined by mere observation" (1975, p. 261), and "can be

decided merely by the application of our sense-organs" (p. 265). Dummett takes it to be a consequence of the observationality of a predicate like "red" that it is "governed by the principle that, if I cannot discern any difference between the colour of *a* and the colour of *b*, and I have characterized *a* as red, then I am bound to accept a characterization of *b* as red" (p. 264). The justification is that a predicate could not be applied simply on the basis of how things look, and so could not be observational, if an indistinguishable difference could determine the predicate's differential applicability.

To use this thought to ensure paradoxical truth-values for the elements of sorites arguments, we could define the observationality of φ as follows:

> if α satisfies φ and, under normal circumstances for observation for φ, β is indistinguishable from α, then β satisfies φ.

If adjacent members of a sorites series count as indistinguishable, this ensures that observational predicates are paradoxical. But it is questionable whether there are any non-trivial observational predicates, thus defined. Consider "looks red" as a strong candidate. Suppose that α and β are indistinguishable under, say, standard lighting conditions, and so on. Then one might argue: their indistinguishability entails that they look the same; so if α looks red, so does β; so the condition for "looks red" being observational is met. So there is at least one observational predicate.

The notion of indistinguishability is crucial to this argument, but it has not been adequately explained. To show the complexity, consider a case in which regions on the wall are exposed to a subject in a random order (the "random sorites"), and he is asked to say of each region whether it looks red. We then score the result by writing a "Y" beneath a region if the subject said "Yes" with respect to that region, an "N" if he said "No," and a "0" otherwise. What would the score of a perfectly rational subject look like, assuming conditions of observation to be normal for "looks red," and assuming that his eyesight and mastery of the predicate are both perfect? There will certainly be a "Y" beneath at least one of the left-hand regions, and an "N" beneath at least one of the right-hand regions; there will be no "0" to the left of a Y, and no "N" to the left of a "0." But there will certainly be a Y-region, call it α, which has a "0" or "N" adjacent to it and to its right, that is, at α'.

Given the assumptions about the rationality of the subject and the perfect conditions for observation, one might conclude that he has not made a mistake about how things looked to him, even though distinct rational subjects, and the same subject on different occasions, will draw the line in different places. This means that there is no mistake in supposing that α satisfies "looks red" and α' does not. We could infer that adjacent regions of the wall are not, after all, indistinguishable, for a rational subject, without error, made a distinction between them. In that case, we will be hard put to find sorites series with indistinguishable members, and so will be hard put to use the notion of observationality to justify the premises of arguments of types (A) and (B).

Alternatively, we might insist that the adjacent regions of the wall are indistinguishable (for example, because they look the same when co-presented), but then we must say that "looks red" does not satisfy the envisaged condition for being an observational predicate.

Either way, observationality has no impact on the sorites paradoxes.[8] This is what one would have predicted on the supposition that all sorites paradoxes should be accounted for in the same way, for there are many sorites-paradoxical predicates which have little claim to observationality, such as "child," "dog," "know," and "few." Even for those for which observationality is

at issue, like "red" or even "heap," we can generate a sorites series in which the adjacent members are discriminable. Intuitively, a patch which differs only just discriminably from a red patch should count as red; and, as we saw, the paradox of the heap is quite impervious to the assumption that the various collections differ in size, in a potentially knowable way.

2.2.2 The Nature of Vagueness

The semantic conception of vagueness holds that it is of the nature of a vague predicate to draw no sharp boundary between the things to which it applies and those to which it does not. Arguably, this could be expressed precisely as the QP of schema (A), as the conditionals of schema (B), and as a denial of the QC of schema (C). So we have an argument for the paradoxical distributions based on a claim about the nature of vagueness.

Resisting this argument requires, from the perspective of the semantic conception, adjustments to classical logic or classical semantics or both. Perhaps one can persuade oneself that an adequate account of the nature of vagueness should not entail QP. We don't believe a tadpole can turn into a frog in a millisecond, but perhaps we can refrain from holding that it is in general true that anything which is a tadpole at a time is also a tadpole a millisecond later: we see too clearly where that belief would lead. So perhaps there is no immediate argument from the nature of vagueness to the truth-value distributions required to make arguments of type (A) paradoxical.[9] But there is a less immediate argument. Suppose we are happy to resist QP, that is, to hold that it is not true. Then the natural thing to say is that it is false; but this commits us to the truth of its negation, which is classically equivalent to QC: $\exists x(\varphi x \,\&\, \neg\, \varphi x')$. So we sever a direct connection between the nature of vagueness and the paradoxical truth-value distributions, only to force into view a less direct connection. Perhaps we could hold that QP is not true, yet not that it is false; perhaps this would be enough to avoid the unwelcome QC and also avoid the paradox-inducing QP. However, we would need an account of an appropriate non-classical semantics, and a justification for the specific treatment of QP.[10] The general moral, then, is that a semantic view of vagueness requires non-classical semantics and/or non-classical logic.

2.3 Alternative Logics and Semantics

On the semantic view, it would be desirable to be able to say that QP is not true without being forced to say that QC is true; and desirable to be able to say that at least one conditional from schema (B) fails, without having to say that one of them is false. (The envisaged conditionals are material, so a false one has a true antecedent and a false consequent.)

To do this, one would have to abandon bivalence. There are two ways to proceed. We can use a bivalent metalanguage to describe a non-bivalent object language. Well-known examples are given in §2.3.1 and §2.3.2. Or we can use a non-bivalent metalanguage to describe our non-bivalent object language. An example is sketched in §2.3.3. On the first alternative, we can keep to classical conceptions of sets and models: vagueness is then tamed, described in essentially non-vague terms. On the second alternative, vagueness is never eliminated, never sharply described.

2.3.1 Supervaluations

If an expression is vague, we believe it could, in theory, be replaced by a more precise one. Thus we could replace the vague "child" by the more precise "minor" (meaning person who has not yet reached the day of his or her eighteenth birthday). Not every replacement would

be acceptable: if "minor*" is defined as a person who has not yet reached the day of his or her fifth birthday, the word is nowhere near "child," since it would be clear that some children are not minors*. Equally, the expression "minor′," defined as a person who had not yet reached his or her thirtieth birthday, would be unacceptable, since it would be clear that some minors′ are not children.

An important line of thought about vagueness is that this notion of an acceptable way of making an expression more precise can be used to specify the meaning of a vague expression: its meaning will be given in terms of all the ways in which it could acceptably be made precise, where an acceptable way is one not precluded by the meaning it has. An acceptable way does not make the extension of the term too narrow, like that of "minor*," or too wide, like that of "minor′." A sentence containing a vague expression is to count as true, if it is true however that expression is made precise, and to count as false if it is false however that expression is made precise. This makes room for cases in which the sentence is true on some ways of making it precise, false on others; and, hence, in which it is neither true nor false.

In a classical model, a (unary) predicate is associated with a set of entities from the domain. Using the idea of the previous paragraph, we could associate a vague unary predicate with a range of sets, the sets corresponding to the acceptable ways in which it could be made precise.

This approach has been developed with formal elegance in a kind of model theory called supervaluation theory.[11] In addition to starting from an appealing conception of vagueness, it offers two further charms: it promises a precise description of a vague language; and it promises to preserve classical logic.

Let us think of a model, M, for a language, L, as an ordered pair $\langle D, F \rangle$ of a domain, D, and a family F of valuation functions, each mapping each unary predicate of L on to a subset of D and each name of L on to a member of D. (For simplicity, we will assume that all the non-logical symbols of L are either unary predicates or names.) Suppose that for some predicate, φ, of L, every member f of F meets these conditions:

if x is in D and is definitely a satisfier of φ then x is in $f(\varphi)$.
if x is in D and is definitely not a satisfier of φ then x is not in $f(\varphi)$.

Then we shall say that M is *appropriate* for φ. A model is appropriate for a language iff it is appropriate for all its expressions.[12] An appropriate model is *maximal* iff any addition to its family of valuations would render it inappropriate. Maximal models are supposed to represent the semantics of languages with vague predicates.

Within any model, truth-relative-to-a-member-f-of-F (abbreviation: truth$_f$) is defined in the usual classical way:

⌜φα⌝ is true$_f$ iff f(α) is in f(φ);
⌜A & B⌝ is true$_f$ iff f ⌜A⌝ is true$_f$ and ⌜B⌝ is true$_f$;
... and so on.
⌜A⌝ is false$_f$ iff ⌜A⌝ is not true$_f$.

Truth and falsity (relative to a model) are defined by generalizing over valuation-relativized truth: ⌜A⌝ is true in M iff ⌜A⌝ is true$_f$ for every f in F; ⌜A⌝ is false in M iff ⌜A⌝ is false$_f$ for every f in F. Truth and falsity are thus "supervaluations" relative to the basic bivalent valuations in F. This allows for borderline cases to induce a failure of bivalence in maximal

models. Suppose that a member α of D is not definitely a satisfier of φ and also not definitely not a satisfier of φ. And suppose that $M = \langle D, F \rangle$ is maximal. This means that there is a member of F, say f_1, such that $f_1(\varphi)$ contains α, and a member of F, say f_2, such that $f_2(\varphi)$ does not contain α. So "φα" is true_{f1} and false_{f2}. So "φα" is neither true nor false in this model.

Although supervaluation theory treats the object language as non-bivalent, the Law of Excluded Middle is preserved, that is, the schema $\ulcorner A \vee \neg A \urcorner$ is valid. Consider the instance of it with φ and α as in the previous paragraph. It will be true_f for every f, since for every valuation either $f(\alpha)$ is in $f(\varphi)$ or it is not, and in the first case the disjunction will be true_f in virtue of the truth_f of its first disjunct, and in the second case in virtue of the truth_f of its second. In supervaluation theory, a disjunction can be true without either disjunct being true.

Validity can be defined as usual: an argument is valid iff every model in which all the premises are true is one in which the conclusion is true. The class of valid arguments thus defined is identical with the class of classically valid arguments.[13] Hence arguments following schemas (A), (B), and (C) are all supervaluationally valid; but sorites instances of schemas (A) and (B) are unsound. We will first show how this is so, and then consider what the supervaluational theory has to say about instances of (C).

By the definition of appropriateness, the valuations in an appropriate maximal model will place intuitively definite cases in the extension of any vague predicate, and exclude intuitively definite non-cases from its extension. For "heap," each f will associate the predicate with a set of collections (of grains of sand, say), where one collection is the smallest, and the set also contains all larger ones.[14] In other words, every f will associate the predicate with a sharp threshold, though, because of the predicate's vagueness, the different valuations will associate it with different thresholds. For any f in F, one conditional is false_f: the conditional which, for the line drawn by f, has an antecedent referring to an object on one side of the line and a consequent referring to an object on the other. Hence at least one conditional (typically, several conditionals) in the premises of schema (B) will fail to be true.

Similar facts ensure that QP in schema (A) is not merely not true, but false. The singular instances of QP are the conditionals which are the premises of (B). Since every f in F falsifies one of these conditionals, every f falsifies QP.

Many objections have been leveled at supervaluational theories. We list two.

The Truth of QC

The supervaluational theory has it that instances of (C) are sound, and thus have a true conclusion, QC: $\exists x(\varphi x \,\&\, \neg\, \varphi x')$. If we find this hard to swallow, we are asked to remember that, in the presence of vagueness, quantifiers do not work in the normal classical way. In particular, using "satisfies" on the lines of "true," there is no sound inference from the truth of QC in the model to the conclusion that there is something in the domain of the model which satisfies "$\varphi x \,\&\, \neg\, \varphi x'$." The supervaluation theorist could claim that only the existence of such an object would amount to the existence of a sharp cut-off; so the truth of QC does not entail a sharp cut-off; so one is confused if one thinks that one wants to deny QC.

By itself, this is unlikely to be very persuasive. It seems plain that one can use our ordinary language to express absence of a cut-off, without having to ascend into the metalanguage, as this response supposes.

However, it is plausible that an object-language account of what it is for a predicate to be vague involves, at least in the first instance, the use of some expression representing definiteness, or, equivalently, vagueness. One wants to say, for example, that "red" is vague because there are things which are neither definitely red nor definitely not red; or that it is

vague because there are things concerning which there is no fact of the matter whether they are red or not. More formally, we might say that any vague language could be expected to be capable of expressing its vagueness, perhaps by a sentence operator, "Def," expressing definiteness.[15]

The supervaluation theorist would do well to claim that something like this operator must be used in saying what we want to say about vague predicates and cut-offs: what we really want to say is that there is no *definite* cut-off point. This is properly expressed not by denying QC, but rather by denying "$\exists x\mathrm{Def}(\varphi x \,\&\, \neg\, \varphi x')$." This means extending supervaluation theory to deal with "Def."

From a supervaluationist's point of view, "Def" should resemble an object-language expression of the notion of truth (by supervaluational lights).[16] Thus "Def A" should be true-on-a-valuation iff A is true (that is, true-on-every-valuation). This makes "Def" in some ways like "$\Box$" ("$\Box$A" is true-at-a-world iff "A" is true-at-every-world). In particular, taking the analogy in the most straightforward way, "Def" would eliminate vagueness: applied to any sentence, the result is one which is true on all or on no valuations.

However, there are two important points of disanalogy between "Def" and "$\Box$." First, if the supervaluationist retains the definition of validity as, in effect, necessary preservation of truth, he must agree that once "Def" is added to the object language, certain classical forms of reasoning (conditional proof, *reductio ad absurdum*, and *or*-elimination) cannot be allowed to be valid.[17] Second, if there is higher-order vagueness, then vagueness should not be eliminated by "Def."

Problems with Higher-Order Vagueness

A supervaluational model is intended to divide the sentences of the language into three sets: the truths, the falsehoods, and the remainder. There will be adjacent members, α and α', of a sorites series such that α is the last truth in the series and α' the first non-truth. But many find this unacceptable: they claim that there is no more a sharp boundary between the truths and the borderline cases than there is between the truths and the falsehoods.

The notion of a supervaluation is itself vague: it is defined in terms of an acceptable model, which is in turn defined in terms of what definitely falls under a predicate and what definitely does not. These notions admit of borderline cases: the reasons for saying that, for example, there is no fact of the matter whether certain color patches are red support with no less strength the conclusion that there is no fact of the matter whether certain patches are *definitely* red. Equally, the reasons for thinking that there is no last region of the wall which counts as red support with no less strength the conclusion that there is no last region on the wall which is definitely red. If the conclusion is correct, there will be a valuation such that there is no fact of the matter whether or not it is appropriate.

One ensuing problem is that in an object language in which there is higher-order vagueness, "Def A" is neither true nor false for some A; so the truth-conditions for "Def" cannot be given in the simple way envisaged earlier ("Def A" is true-on-a-valuation iff A is true). One response draws inspiration from possible-worlds semantics for modality: one would need to introduce an analogue of the accessibility relation, holding between valuations, and this would need to be reflexive (to validate "Def A → A") but not transitive (in order not to validate "Def A → DefDef A").

A deeper problem is that the supervaluationist's notion of truth as truth-on-all-appropriate-valuations must itself be vague. This means that a potential charm of supervaluation theory is lost: it cannot, after all, give a precise description of a vague language. It

also raises the question whether the supervaluational concept of truth is correct. Many believe that truth must satisfy Tarski's disquotation schema:

(T) True (A) iff A.

But then, by reasoning which the supervaluationist endorses, it follows that if A is not true it is false.[18] The supervaluationist category of neither-true-nor-false sentences would vanish, and with it the basic idea of supervaluation theory.[19] So the supervaluationist must deny that his concept of truth is disquotational, and this raises the question whether it is, properly speaking, a concept of *truth* at all.

2.3.2 Degrees of Truth

Not all borderline cases for a vague predicate are equal (or so it may reasonably seem). Two patches α and β might both be borderline cases of red, yet one redder than the other: one has a greater degree of redness. So one might be tempted by the following progression: it is closer to the truth to say that α is red than to say that β is red; so truer to say that α is red than to say that β is red; so "α is red" has a greater degree of truth than "β is red."

It is certainly an important feature of many vague predicates, and perhaps of all those which are sorites-susceptible, that the relevant cases are subject to an underlying comparative relation. However, this cannot be taken as any kind of knockdown argument for the existence of degrees of truth, for we have yet to distinguish between the relatively innocuous suggestion that some sentences are nearer to stating the (absolute) truth than others, and the controversial suggestion that some sentences are truer than others. We might make some progress towards the more exotic suggestion by reflecting on the following lines: truth is what one should aim at in belief, but for borderline cases the best you can aim at is degrees of belief; so we must be able to make sense of a notion of degrees of truth.

Whatever the philosophical motivation, semantics based upon degrees of truth have been claimed to dispel sorites paradoxes.[20] In the models $\mu = \langle \delta, \Phi \rangle$ which we now consider, δ is a domain of individuals, and Φ assigns to every name in the language a member of δ, and to each predicate, φ, a J-set, $\Phi(\varphi)$. A J-set is a mapping of members of δ into the real numbers in the closed interval [0,1]. Intuitively, the idea is that the number which is the value of the mapping for the member of δ which is the argument – the "J-value of $\Phi(\varphi)$ for δ" – represents the degree of truth, relative to assignment Φ, associated with affirming φ of that member. The value 1 represents an object to which the predicate definitely applies, the value 0 represents an object to which the predicate definitely does not apply, and the intermediate values represent intermediate cases. Writing $[P]_\Phi = n$ to express the fact that the sentence P is assigned the degree of truth n by function Φ, atomic sentences are assigned degrees of truth by rules like: $[\varphi\alpha]_\Phi$ is the J-value of $\Phi(\varphi)$ for argument $\Phi(\alpha)$. Appropriate models assign J-sets which reflect actual usage, that is, lead to assignments of degrees of truth to atomic sentences which both preserve our intuitive orderings (such as our ordering of how red the patches on the wall are) and conform to our intuitions about definite truths (assigned 1) and definite falsehoods (assigned 0).

The theories we discuss treat the logical constants as degree-functional: that is, the degree of truth of a complex is a function of the degrees of truth of the constituents. There are various possible functions. One standard approach is to stipulate as follows:

$$\begin{aligned}
&\left[\neg \mathrm{P}\right] = 1 - \left[\mathrm{P}\right] \\
&\left[\mathrm{P} \,\&\, \mathrm{Q}\right] = \min\left\{\left[\mathrm{P}\right], \left[\mathrm{Q}\right]\right\} \\
&\left[\mathrm{P} \vee \mathrm{Q}\right] = \min\left\{\left[\mathrm{P}\right], \left[\mathrm{Q}\right]\right\} \\
&\left[\mathrm{P} \rightarrow \mathrm{Q}\right] = 1, \text{if} \left[\mathrm{Q}\right] \geq \left[\mathrm{P}\right], = 1 - \left(\left[\mathrm{P}\right] - \left[\mathrm{Q}\right]\right) \text{otherwise.} \\
&\left[\forall v \mathrm{A}v\right] = \mathrm{glb}\left\{\left[\mathrm{A}^{a} / v\right] : \text{for all a}\right\} \\
&\left[\exists v \mathrm{A}v\right] = \mathrm{lub}\left\{\left[\mathrm{A}^{a} / v\right] : \text{for all a}\right\}^{21}
\end{aligned}$$

The functions give the classical results if the arguments are restricted to 1 and 0. The specific idea behind the equation for ¬ is that there is no difference between departing from definite truth (that is, value 1) and approaching definite falsehood, and that predicates have paradigm borderline cases (such as α for φ) for which we want [φα] = [¬φα]. The specific idea behind the equation for → is that a conditional should fall short of perfect truth to the extent that truth leaks away as between antecedent and consequent.

One standard account of validity within degree theory is based on a generalization of the notion of truth-preservation: a valid argument is one such that every model assigns a degree of truth to the conclusion no lower than that assigned to the lowest-valued premise. However, Edgington (1992) has argued that it would be better to give a different account, based on the idea that validity does not permit additional falsehood: a valid argument is one such that every model assigns a degree of falsehood to the conclusion which does not exceed the sum of the degrees of falsehood it assigns to the premises.

One impact of this view upon the sorites is that arguments of type (A) and type (B) will be seen as having at least one premise which is not entirely true. Thus the truth-values of the components of the conditionals of (B) progressively fall, and a conditional with a consequent less true than its antecedent will not be entirely true. For similar reasons, the QP of (A) is also not entirely true. Hence, on this approach, the impression that the sorites arguments are sound is, for these cases, supposedly dispelled by dispelling the appearance of (fully) true premises.

On the more common definition of degree-theoretic validity, generalizing from truth-preservation, none of the argument patterns we have discussed is valid. For example, type (B) is not, because *modus ponens* is, by this standard, not valid in degree theory. For suppose that $[P] = 0.9$, and $[Q] = 0.8$. Then $[P \rightarrow Q] = 0.9$. So an argument of the form:

$$P, P \rightarrow Q \therefore Q$$

has a lowest-valued premise of 0.9, and a conclusion valued 0.8.

Whichever definition of degree-theoretic validity one uses, arguments of type (C) are invalid, for the premises will have degree 1 and the conclusion a degree of around 0.5. So the apparent soundness of some versions of the sorites arguments is supposedly dispelled, through dispelling the appearance of validity.

However, the degree-theoretic account is open to various objections. We mention three.

It Does Not Do Justice to QC

In connection with (C), natural assumptions about the existential quantifier in degree theory have the result that QC does not come out as false (=0) but only as midway true. A defense of degree theory would have to claim that what should really have degree 0 is not QC itself, but rather "$\exists x\mathrm{Def}(\varphi x \,\&\, \neg\, \varphi x')$." The required extension of the theory to an object language containing "Def" is not straightforward. If the sentence just quoted is to receive degree 1, it would seem that [DefA] = 0 iff [A] < l. This means that "Def" would eliminate vagueness, and thus would not allow for higher-order vagueness.

Its Logic is Unintuitive and Unmotivated

People have found the assignments of degrees to complexes unintuitive and unmotivated. For example, "P v $\neg\, P$" will be as true as "P & $\neg\, P$" when $[P] = 0.5$. Similar unintuitive results are obtained when the sentences stand in non-formal logical relations. Thus suppose Eve is definitely female but a borderline case for being an adult, so that [Eve is an adult] and [Eve is a woman] are both 0.5. Degree theory cannot distinguish between "Eve is a woman if and only if Eve is an adult" and "Eve is a woman if and only if Eve is not an adult," assigning both 1.[22]

Even certain sentences which may be critically involved in some versions of sorites arguments are treated by this degree theory in an unintuitive way. Thus a classical equivalent of QP, "$(\forall x)\neg\, (\varphi x \,\&\, \neg\, \varphi x')$," will be assigned a value of about 0.5, whereas intuitively it ought to come out as nearly true.

It Does Not Do Justice to Higher-Order Vagueness

The degree-theoretic property of having degree of truth 1 is supposed to correspond to some intuitive property (or else the formal semantics cannot connect with the informal judgments of truth and validity which underlie sorites paradoxes). Perhaps it is that of being true, or of being definitely true, or of being completely, definitely, and unimpugnably true. Whatever property we choose, we have something unsatisfactory: since having degree 1 is a sharp property, the corresponding truth-related intuitive property must be sharp too. In any sorites series there is a last sentence having truth to degree 1; hence there is also a last sentence with the relevant truth-related intuitive property. But it is natural to suppose that there is no such sharp cut-off: whatever property we consider, true to a certain degree, absolutely true, definitely true, or completely, definitely, and unimpugnably true, there are no adjacent members of the sorites series one of which lacks, while the other possesses, this property.[23]

2.3.3 A Non-bivalent Metalanguage

It is hard to see how there could be a more accurate account of what you should aim to do, in using a vague word like "red," than that, if you want to keep to the truth, you should apply it just to red things. This suggests that we should look for a semantic theory which unashamedly uses vague vocabulary in the metalanguage. In particular, we wish to mention a theory recently proposed by Michael Tye (1994).[24]

His proposal is based on three semantic values: true, false, and indefinite. The connectives are assigned values as follows: a negation is true iff its component is false, false iff its component is true, otherwise indefinite; a conjunction is true iff both components are, false iff one component is, otherwise indefinite. Universal quantifications are true iff all their instances are, false iff an instance is, otherwise indefinite. So the premises of sorites arguments of schemata (A) and (B) are indefinite, and not true. These argument-patterns are not sound.

Merely having three values is of no help in itself, once higher-order vagueness is admitted, as we saw in the case of supervaluation theory. For example, suppose that in a sorites series of sentences there is a last which is assigned truth. It makes no difference whether the next sentence is assigned falsehood or some other value: either way, we have a boundary where, according to many intuitions, no boundary should be. Tye deals with this by saying that there is no fact of the matter whether all sentences have one of the three truth-values. Hence the claim that, for example, there is a last true sentence in a sorites series is vague, and not true. Once again, we would not have the making of soundness in sorites arguments. If this strategy works at all, it should work as well with just two truth-values, distributed in a similarly vague way.

To obtain truth-conditions for atomic sentences, Tye associates a predicate with a vague set, a set concerning which there are things for which it is vague whether they are members of it. Thus the approach involves recognizing vague extra-linguistic entities, which is controversial.

A problematic feature of his account is that indefiniteness in a component of a complex sentence can render the whole sentence indefinite regardless of its form. Thus "if *P* then *P*" is indefinite if *P* is, yet many find it compelling to regard it as true however things are with *P*. To take an example closer to the sorites, consider the reverse of QP:

RQP $\quad \forall x\left(\varphi x' \rightarrow \varphi x\right)$

Applied to the wall, this says that if a region further to the right (towards the yellow end) is red, so is the adjacent region to the left; so it is intuitively true. But on Tye's semantics, it is not true, since the truth of a quantification requires the truth of its instances, and some of these conditionals will have indefinite components, and thus be themselves indefinite. Intuitively, however, RQP is true, and corresponds to what some would see as a constitutive principle: anything redder than a red thing is red.

It is not clear which features of Tye's account are essential. As we have mentioned, the third value could not be essential to dealing with the sorites (even if it is required for the best description of the use of language). It may be that the apparently implausible features can be removed, or shown not to be implausible after all. However, if higher-order vagueness is a genuine semantic phenomenon, there cannot be a precise semantic theory for a vague language. It is plausible to infer, as Tye in effect does, that in this case we must abandon a conception of semantics as making, for every sentence of a language, some definite pronouncement (such as that it is true, false, or indefinite): there will have to be sentences for which there is no definite fact of the matter concerning what the semantic theory says about them, and this must be distinguished from the semantic theory saying that there is no definite fact of the matter concerning their semantic value. Thus Tye's approach requires semantic theories to be, in a sense, incomplete.

2.4 The Epistemic View[25]

All these problems would be solved on the epistemic view, according to which there really are sharp cut-offs, though we cannot identify them. We cannot identify them because we do not have the required fineness of discrimination: we must allow for a margin of error in our cognitive mechanisms. If we know of a region of the wall that it is red, we could not know of its neighbor to the right that it is not red (even if in fact it is not red); for we could not reliably distinguish shades which differ so little.

Arguments of type (C) are seen as sound demonstrations of the epistemic view. Arguments of types (A) and (B) are valid on the view, and establish the falsehood of a premise by *reductio ad absurdum*. There is no problem about denying QP and accepting QC, and no problem about regarding one of the conditionals in type (B) arguments (though one does not know which) as having a true antecedent and false consequent. One can retain all the simplicity of classical logic and semantics.

The epistemic view thus has plenty to be said for it, yet it often evokes incredulity. Those who see any merit in the rule-following considerations advanced by Wittgenstein, and his denigration of the notion of imperceptible rails upon which the correct usage of language is supposed to run, are likely to be particularly hostile to the epistemic position. However, it is easier to identify generalized hostility than precisely formulated opposing arguments. In this section, we try to give voice to two connected objections.

There is No Evidence that Vague Concepts Induce Sharp Cut-Offs

The point of this objection is to claim that the main reasons in favor of the epistemic view are quite general, like arguments of type (C), whereas what would be needed would be a detailed examination of how specific vague concepts actually work. The suggestion is that nothing in the details of how they work would ground the view that they are associated with sharp cut-offs.

However, at least for some vague concepts, close examination reveals some surprisingly rich cut-off-determining principles. Consider that paradigm of vagueness, "heap."[26] A heap of φs must be heaped up, and this involves at least one φ stably above another, but not in virtue of glue-like attachment. Thus grains of sand spread out in such a way that no grain is on top of another cannot be a heap, however many grains there are. Moreover, gluing grains together in such a way that some grains are on top of others is not a way of making a heap. It seems to be of the essence of heaps that they are held together by gravity alone. The arrangement must also not be that of a stack: a dry stone wall is not a heap of stones. If we think of roundish things like grains of sand, it would appear that the smallest stable arrangement meeting these conditions requires four of them: three grains close together supporting a fourth on top. Here we arguably have a sharp cut-off. (The governing principles may well not determine the same cut-off for every shape of object.) An argument of this kind is at best suggestive, and it is always open to the conventional theorist to say that we were wrong in counting as vague some predicates for which such cut-off-determining principles can be discovered. The conventional theorist may be on safest ground with color predicates.

The Epistemic View Does Not Do Justice to the Fact that Meaning Supervenes on Use

"Meaning is use": that is, semantic facts concerning a language supervene on facts about the linguistic behavior of masters of that language. Can the epistemic view do justice to this?

By "meaning supervenes on use" one might mean just that if two communities used a language in just the same way, then every sentence of the language would have the same meaning in both communities. By this standard, the epistemic theory of vagueness can certainly claim that meaning supervenes on use.

A much more stringent demand is that a theorist should provide explicit details of how meaning supervenes on use. Since no theorist of any kind (whether or not vagueness is at issue) has given any such detailed account, the fact that the epistemic theorist has not should not count against the theory.

However, the supervenience doctrine can be used to generate demands of a strength intermediate between the extremely weak and extremely strong demands of the previous two paragraphs. For there may be *a priori* principles relating to conditions under which supervenience is possible.

One proposed principle of this kind is verificationism. On the verificationist view, meaning can supervene on use only through knowledge: a sentence cannot have a meaning such that it would be impossible for those who understand it to determine whether it is true or false. Since the epistemic view holds that it is impossible for us to know where the cut-offs come, the view is inconsistent with the verificationist constraint upon the supervenience relation. However, since verificationism, at least in the strong form envisaged, now has few supporters, it does not pose a serious threat to the epistemic view.

One does not have to be a verificationist to feel qualms about whether the epistemic view can do justice to the supervenience of meaning on use. For example, one might hold that if a predicate stands for a manifest property (one which under some conditions detectably obtains), then under optimal conditions for manifestation, if there is a fact of the matter whether or not it obtains, that fact is detectable. This is not full-blown verificationism, for it is consistent with there being properties which are not manifest, and consistent with it being impossible for us to detect even manifest properties, to the extent that it is impossible for us to bring about optimal conditions. Yet, it might be claimed, we can view a region of the colored wall under optimal conditions without being able to detect the presence or absence of redness; and the view then delivers that there is no fact concerning whether the region is or is not red.

Clearly the epistemic theorist will take issue with this line of thought, challenging, among other things, what is taken for granted in the notion of optimal condition for manifestation (cf. Williamson, 1994, pp. 180–184). Until these issues are clarified and resolved, some caution about the epistemic view is called for. However, we are not aware of any decisive refutation of it, and it would provide a breathtakingly simple solution to sorites paradoxes.[27]

Notes

1 The account of the sorites in antiquity draws heavily on Barnes (1982) and Burnyeat (1982). The most important ancient texts are translated in Long and Sedley (1987, vol. 1, pp. 221–225). For more on the history of the sorites see Williamson (1994).

2 The Stoics were not sure that any wise men had lived; they may also have held that only a wise man would know anything at all. Nevertheless, knowledge was what the Stoics aimed at. The argument in the text could still be made with "justified true belief' in place of "knowledge."

3 See below, §2.2.

4 Leibniz (1961, III v 9 and III vi 27); see Wiggins (1980, p. 124).

5 It is now customary to distinguish between the Law of Excluded Middle, which requires the validity of the schema "Either *A* or not *A*," and the principle of bivalence, of which one formulation is that every sentence is true or false. (In §2.3.1 below we describe a theory which preserves the Law while rejecting the Principle.) Russell is best understood as rejecting the latter.

6 For this formulation, see Rolf (1984, p. 220).

7 Cf. Dummett (1975, pp. 251–252). Kamp (1981, pp. 226–27) provides an independent reason for the same conclusion.

8 The reason offered here for this conclusion can be found in Wright (1987, p. 283, especially n. 13) and Williamson (1990, pp. 88–103).

9 In particular, it is reasonable to suggest that our intuitions about vagueness are properly expressed only using some expression for definiteness. Cf. Wright (1987; 1992).

10 We would, in particular, need an account which allowed that something not true can yield a falsehood, without itself being false.

11 This form of theory was systematically applied to vagueness by Dummett (1975), Fine (1975), Kamp (1975), and Lewis (1970). Fine traces the origins of the idea, as applied to vagueness, to Mehlberg (1958). The use of the expression "supervaluation" goes back to van Fraassen (1966), though he was concerned not with vagueness but with the semantic paradoxes. A glimmering of the idea is found in Russell's suggestion that vagueness is a matter of a one–many relation between words and world (1923, p. 89). Supervaluation theory can be cast in a bivalent metalanguage, and this may have been part of the theory's appeal. However, it can also be cast in a non-bivalent language, as we in effect point out elsewhere (p. 748 and n. 17).

12 Complex predicates must be included, since an appropriate valuation must respect what Fine (1975) has called "penumbral connections" between predicates. Thus a valuation which ensures that "Eve is a female child" is true must also ensure that "Eve is a girl" is true, to respect the intuition that, definitely, nothing satisfies "*x* is a female child and not a girl." Vague names, if there are such things, could be treated just like vague predicates: different valuation functions within a model's family may assign them to different things. But for the moment it will be best to imagine that all assignment functions, or at least all appropriate ones, agree on what they assign to names.

13 If the envisaged definition of validity is retained, this depends upon the assumption that "Def" is not in the object language; see p. 748 and n. 17; and see Williamson (1994).

14 This makes the assumption that arrangement is held constant. It follows that if an *n*-membered collection is a heap, so is any collection with more than *n* members.

15 Thus Wright (1987; 1992) suggests that the notion of there being no sharp boundary can be non-paradoxically expressed using such an operator, whereas removing it leads to immediate paradox.

16 This means that it can do something like the work done by the metalinguistic denial that there is something in the domain of the model which satisfies "$\varphi x \,\&\, \neg\, \varphi x'$."

17 Cf. Williamson (1994, pp. 147–153). For example, although one can validly infer "Def A" from "A," if validity is defined in terms of truth-preservation, this does not guarantee the validity of "If A then Def A": if for some model *M*, some valuation, *f*, "A" is true_f, and for some valuation, *g*, "A" is false_g, then the conditional is false_f and so not true in *M*, so not valid. The supervaluationist might, therefore, prefer to exploit, in his account of validity, a different similarity with the classical definition. His idea is that questions of truth arise only relative to ways of making precise, and he extends this from atomic sentences to complex ones in terms of making the whole complex sentence precise. In this spirit, he might treat validity similarly, defining it in terms of making precise the whole argument. Then, the right thing to say would be that a valid argument is one for which every valuation verifying the premises verifies the conclusion. (As sentence connectives are, in supervaluation theory, valuation-functional but not truth-functional, so with arguments.) It would seem that this would restore the classical character of supervaluational validity. (We are grateful to Dominic Hyde for discussion of this point.)

18

(1)	not True (A)	assumed
(2)	True (A) iff A	(T)
(3)	not A	from (1) and (2) by classical prop. logic
(4)	True (not A) iff not A	(T)
(5)	True (not A)	from (3) and (4) by classical prop. logic
(6)	False (A)	from (5), given that a negation is true iff what it negates is false

This argument will not be persuasive for those theorists who adopt some non-classical logics, e.g., those involving distinct notions of negation.

19 For discussions of the relation between supervaluation theory and higher-order vagueness, see Fine (1975, especially §5), and Williamson (1994, pp. 156–164). On higher-order vagueness more generally, see Heck (1993) and Wright (1992).
20 A classic formulation is Goguen's (1969).
21 "glb" and "lub" abbreviate "greatest lower bound" and "least upper bound" respectively. These are the infinitary analogues of min and max. "$[A^a/v]$" abbreviates "the result of replacing every occurrence of "v" in "Av" by some name not in "Av." Cf. Forbes (1985, p. 174).
22 Supervaluation theory, by contrast, treats the first as neither true nor false and the second as false. This is the problem Fine (1975) calls that of "penumbral connection," and he regards the way in which supervaluation theory handles it as an important merit of the theory.
23 Degrees of truth can be defined within the supervaluational approach: roughly, $[\sigma]$ is the probability of σ being true on a randomly chosen sharpening. Cf. Lewis (1970), Kamp (1975), Edgington (1992), and Williamson (1994, pp. 154–156). However, the two accounts differ on the proper treatment of the logical constants, and they have very different philosophical motivations.
24 See also Horgan (1993), who offers a different non-bivalent account in an article which came to our attention too late to be discussed here. We saw above that supervaluation theory could be modifed so as to allow that its concept of a sharpening is vague (and we mentioned that certain objections would still remain); so it could have featured in both the bivalent and non-bivalent categories of our taxonomy.
25 Early postwar versions of the theory can be found in Cargile (1969) and Campbell (1974). For more recent versions, see Williamson (1992), Sorensen (1988, pp. 217–252), Sperber and Wilson (1986), and Williamson (1994, pp. 185–247).
26 Cf. Hart (1991/1992), though he does not embrace the epistemic view.
27 We thank the editors, Bob Hale and Crispin Wright, for helpful comments on an earlier draft.

Postscript

AIDAN MCGLYNN

Vagueness and the sorites paradox have continued to be areas of intense focus in the past 20 years. This short appendix cannot possibly do justice to the rich and sophisticated treatments developed in this period, and so instead I offer an overview of some central trends, positions, and points that have emerged.[1]

1 Supervaluationism, Degree Theory, and Epistemicism Revisited

Each of the three principal solutions discussed by Sainsbury and Williamson has continued to be refined and defended. For reasons of space and continuity, I'll focus on the objections raised in Sainsbury and Williamson's discussion.

First, recall Sainsbury and Williamson's objection that adopting supervaluationism forces us to give up certain classically valid rules of inference once we introduce a 'definitely' operator, D, into the object language. Rosanna Keefe has responded that from a supervaluationist perspective, such deviations from classical logic are to be welcomed. D "brings to the object-language the non-classicality of the semantics, since it can be used to capture the fact that some sentence takes the non-classical indeterminate truth-value status" (2000, pp. 178–179), permitting us to express the vagueness of a sentence within the object language. So "the logic of the D operator is appropriately non-classical" (2000, p. 181). Robbie Williams (2008) has questioned whether supervaluationists are committed to logical revisions, arguing that given a plausible assumption about how supervaluationists should understand logical consequence, all of the disputed classical rules are valid even with D in the object language. Moreover, Williams contends that even versions of supervaluationism that are logically revisionary aren't 'damagingly' so, since these logical revisions do not require any revisions to our inferential practices.[2]

Recent work by degree theorists tries to resist the claim that the logics they propose are, as Sainsbury and Williamson allege, 'unintuitive and unmotivated.' For example, if a proposition P receives the value 0.5, then both "$P \wedge \sim P$" and "$P \vee \sim P$" will also be true to degree 0.5, and this has struck many as clearly wrong.[3] John MacFarlane observes that such objections often treat degrees of truth as the *chance* that a proposition is true, and so interpreted it does seem clear that an outright contradiction should receive the value 0. But as MacFarlane notes, "if we are certain that [a contradiction] has degree 0.5, then we will take it to have *no* chance of being completely true" (2010, p. 459). The value 0.5 doesn't reflect maximum *uncertainty* regarding whether a proposition is true, but rather a certain kind of *ambivalence*; it means that one regards it as just as true as false (2010, p. 447).[4] Nicholas Smith (2008, p. 86) also finds the supposedly absurd consequences of degree theories quite intuitive, and he suggests that ordinary speakers frequently agree.[5]

Roy Sorensen has offered a very different version of epistemicism to that defended by Williamson, complaining that the latter makes the unknowability of where the boundary in a sorites series lies too contingent on human epistemic limitations; the kind of ignorance to be explained is '*absolute*' (2001, pp. 13–15, 177). Sorensen's treatment of the sorites paradox is inspired and motivated by his treatment of the 'no-no' paradox. Suppose that you have a sheet of card, and on each side the following statement is printed: 'The statement on the other side of this card is false.' What truth-values should these statements be assigned? We get liar-paradoxical inconsistencies if we try to assign both statements the value true or both false, but the two asymmetrical assignments are consistent. How could one of these statements be true and the other false, though, given their symmetrical situations?

Sorensen's answer is that the no-no is a counter-example to the thesis that every truth has a truthmaker; one of the statements is true and the other false, but *nothing* makes it the case that things are this way around. This explains our absolute ignorance about which statement is the true one; such truths are 'epistemic islands,' since there is no access to them via their truthmakers (2001, p. 175). Sorensen extends this account to explain both how one of the conditionals linking adjacent items in a sorites series could be false while its neighbors are true, and our ignorance of which conditional is the false one.

However, Sorensen's treatment of the no-no paradox has been subject to some serious objections (e.g., López de Sa and Zardini, 2007; 2011; Greenough, 2011). Moreover,

Sorensen's whole account has been subjected to forensic scrutiny by Dorothy Edgington (2005; 2010), and she makes a strong case against it.

2 Quandaries and Intuitionism

A much more radical break with Williamson's epistemicism is Crispin Wright's intuitionism (e.g., 2001; 2003a; 2003b). Wright accepts Williamson's contention that vagueness is at root an epistemic phenomenon, but rather than using this idea to defend classical logic and semantics, Wright takes it as a basis for an argument for intuitionist revisions. Wright treats the paradox as a *reductio ad absurdum* of its major premise, (QP), and so he concludes

$$\sim\forall \mathrm{x}\left(F\mathrm{x} \rightarrow F\mathrm{x}'\right),$$

while refusing to make the (classically valid) step to the 'Unpalatable Existential':

$$\exists \mathrm{x}\left(F\mathrm{x} \wedge \sim F\mathrm{x}'\right).$$

The question is how to motivate such intuitionist restrictions to classical logic.

Borderline cases, according to Wright, present us with *quandaries*, where a proposition *P* presents a quandary to a thinker T just in case: T has considered whether *P*; T does not know whether or not *P*; T does not know any way of coming to know whether or not *P*; T does not know whether there is any way of coming to know whether *P*; and T does not know whether it is even metaphysically possible to know whether *P*. Wright's primary argument for logical revision also requires the thesis that knowledge is closed under known logical entailment (or some refinement of it) and the thesis that propositions making vague predications are known to be subject to a principle of Epistemic Constraint:

$$\left(\mathrm{EC}\right) P \rightarrow \text{it is feasible to know } P$$

Let Bob again be a borderline case of baldness, and let us suppose that the relevant instance of the Law of Excluded Middle,

$$\text{Bob is bald} \vee \text{Bob is not bald}$$

is known. It follows that the following is also known:

$$\text{It is feasible to know that Bob is bald} \vee \text{it is feasible to know that Bob is not bald}$$

But to recognize that borderline cases are quandaries is to recognize that this disjunction is *not* known. Hence, if we know that (EC) holds, we can reject the initial supposition that we know that the Law of Excluded Middle holds in this instance, and this puts pressure on the claim that the Law of Excluded Middle is a logical law (Wright, 2001, p. 66).[6]

I'll briefly mention two objections to Wright's solution. Luca Incurvati and Julien Murzi (2008) contend that a parallel argument can be run against the logical status of the law of non-contradiction, and so Wright's revisionary argument is much more revisionary that he intends, while Sven Rosenkranz (2005) has made a plausible case that Wright's quandaries conception of borderline cases is in fact incoherent (see also Rosenkranz, 2003, and Wright, 2003b).

3 Dialetheism as a Unified Solution

Graham Priest has revived Bertrand Russell's suggestion that the paradoxes of self-reference – the Liar paradox, Russell's paradox, the Burali-Forti paradox, and so on – share a common underlying structure, and so should receive a unified solution (e.g., Priest, 2002). Priest classifies these paradoxes as *inclosure* paradoxes, since they fit *the inclosure schema*. We have an inclosure paradox just when there are monadic predicates φ and Ω and a one-place function δ such that we can construct apparently sound arguments for the following claims:

1. There is a set Ω such that $\Omega = \{x : \varphi(x)\}$ (Existence)
2. If $X \subseteq \Omega$,
   a. $\delta(X) \notin X$ (Transcendence)
   b. $\delta(X) \in \Omega$ (Closure)[7]

Consider the Burali-Forti paradox, which shows that there cannot be a set of all ordinal numbers on pain of contradiction. Here's how to represent the paradoxical reasoning as an inclosure paradox (Priest, 2010, p. 70). $\varphi(x)$ is 'x is an ordinal,' and so Ω is the set of ordinals, which we'll take to be defined as von Neumann ordinals (so that each ordinal is taken to be the well-ordered set of all smaller ordinals). Let $\delta(X)$ be the least ordinal greater than every member of X. $\delta(X)$ satisfies Transcendence and Closure by definition. In the special case where $X = \Omega$, we get the contradiction $\delta(\Omega) \in \Omega$ and $\delta(\Omega) \notin \Omega$: intuitively, the least ordinal greater than every member of the set of ordinals both is and is not a member of the set of ordinals.

To be faced with an inclosure paradox, it's not required that the arguments for Existence, Transcendence, and Closure ultimately prove sound or even valid. However, *dialetheists* like Priest argue that the best response to the paradoxes of self-reference involves taking the apparent soundness at face value, and accepting the resulting contradictions. Triviality is avoided by adopting a *paraconsistent* logic: one lacking the principle of explosion (*ex falso quodlibet*).

Priest (2010) has recently argued that the sorites paradox is also an inclosure paradox, and so since the paradoxes of self-references are to be given a dialetheic solution, so should the sorites.[8] Let F be our vague predicate, and we'll assume it obeys (QP):

$$\text{(QP)}\ \forall x\ \left(Fx \supset Fx'\right)$$

Let $\varphi(x) = Fx$, so that $\Omega = \{x : Fx\}$. This gives us existence. Ω is a proper subset of the series, since the last item in the series is not F. If $X \subseteq \Omega$, then X must also be a proper subset of the series. So there must be a first item in the series not in X. Let this be $\delta(X)$. By definition $\delta(X) \notin X$, giving us Transcendence. But also by definition, $\delta(X)$ is the successor of an item in $X \subseteq \Omega$. So by (QP), $F\delta(X)$, in which case $\delta(X) \in \Omega$. And so we have Closure too. When we let $X = \Omega$, the resulting contradiction is that $\delta(\Omega) \in \Omega$ and $\delta(\Omega) \notin \Omega$, or as Priest puts it (2010, p. 71), the first item in the series that is not F is F. Intuitively, the clash here is between (QP) and the thought that, since the set of Fs is a proper subset of the entire series, then given the ordering of the series there must be a first item in the series *not* in that set.

Note that while Priest thinks that this soritical inclosure reasoning is sound (and so requires dialetheism), he doesn't think that "sorites arguments themselves" are sound (2010, pp. 72, 79–80); that's to say, he doesn't accept the argument from the premise that the first

item in a sorites series is *F* and (QP) to the conclusion that every item in the series is *F*. Different dialetheists have addressed this point in different ways; according to Priest, sorites arguments are blocked by the fact that in a paraconsistent setting, *modus ponens* isn't valid for any conditional that renders (QP) defensible.

Many philosophers find dialetheism deeply unattractive, and importantly, there are specific concerns that can be raised to its application to the sorites. The most pressing begins with consideration of Curry's paradox; one can derive an arbitrary proposition *P* as a theorem, starting with a self-referential conditional that says

If this statement is true then *P*,

and appealing only to the standard introduction and elimination rules for the conditional and Tarksi's disquotational schema (or something like it).[9] Unless blocked, Curry's paradox renders our logic trivial, and crucially it does so without requiring us to pass through a contradiction, and so without an appeal to the principle of explosion. J. C. Beall (2014a; 2014b) has argued at length that Curry's paradox has at least as much of a claim to count as an inclosure paradox as the sorites, but it can't receive a dialetheic solution, putting pressure on the argument for a dialetheic treatment of the sorites.[10]

4 Contextualism and Interest-Relativity

According to *contextualism* about vagueness, vague expressions are characteristically context sensitive in ways that go beyond what we standardly recognize (such as the fact that whether someone counts as 'tall' in a conversational context depends on the relevant comparison class), and these hidden dimensions of context sensitivity explain the allure of (QP), even though it is not true. Though the details vary, the general idea is roughly that when any two sufficiently similar items in a given sorites series are considered, the interpretation of the vague predicate shifts (if it needs to) so that the first falls under it only if the second does too. So whenever we consider whether a pair of adjacent items in a sorites series is a counter-example to the major premise of the relevant paradox, that very act ensures that it is not (e.g., Raffman, 1994). Crucially, though, there is no single context in which every instance of the major premise is true. Contextualism might offer a way to defend classical logic and semantics; however, it is not wedded to a classical picture (e.g., Soames, 1999, ch. 7; 2002).[11]

Jason Stanley takes contextualism to be committed to the claim that vague expressions are indexicals (2003, p. 271), and he contends that this renders the contextualist's explanation of why (QP) is attractive insufficiently general. First, he argues that indexicals do not shift their interpretation under verb phrase ellipsis. Consider an example:

(1) John likes me, and Bill does too.

As Stanley notes, "[t]here is no available interpretation of (1) in which John and Bill are said to like different people" (2003, p. 271). Stanley then constructs a sorites series that exploits verb phrase ellipsis. He imagines a series of arrangements of sand that starts with a clear heap, and where each successive arrangement contains one less grain. Pointing at each arrangement of sand in turn:

> If that$_1$ is a heap, then that$_2$ is too, and if that$_2$ is, then that$_3$ is, and if that$_3$ is, then that$_4$ is, … and then that$_n$ is. (2003, p. 272)

The explanation of why we find each of these conjuncts compelling cannot be that shifts in the interpretation of 'heap' ensure that each conjunct is true as we consider it, Stanley concludes, since there are no such shifts.

Jonathan Ellis (2004) has disputed Stanley's claim about indexicals, while Diana Raffman (2005) contends that contextualists should deny that vague expressions are indexicals. Delia Graff Fara (2000) offers an account that's closely related to contextualism, and which allows her to offer a similar treatment of the sorites paradox while evading Stanley's objection. According to Fara, vague expressions are no more context sensitive than ordinary thought, but "the semantics of vague expressions renders the truth-conditions of utterances containing them sensitive to our interests" (2000, p. 49). Here the role our interests play is not in fixing the interpretation of an expression like 'heap' in a context; rather, they play a role in determining whether the (relatively) context-invariant standards for being a heap are met.[12]

However, Stanley's objection is a version of a more general worry, namely that (QP) remains compelling even when we hold fixed all of the features relative to which any boundaries in the associated sorites series supposedly shift. If that's right, then the general explanation of why we are taken in by (QP) cannot be that hidden shifts ensure that we never confront a counter-example to it.[13]

Notes

1 To keep things manageable, I bracket issues concerning higher-order vagueness, though I offer references in the notes and in the suggested further reading.

2 See McGee and McLaughlin (1994) and Asher, Dever, and Pappas (2009) for other developments of broadly supervaluationist approaches that claim to preserve classical logic, and see Keefe (2000, ch. 8) and Asher, Dever and Pappas (2009) for supervaluationist treatments of higher-order vagueness.

3 I leave aside versions of degree theory on which the connectives are not truth-functional and so which lack this result (e.g., Edgington, 1997); see Smith (2008, pp. 263–264) for discussion.

4 Unlike other defenders of a degree-theoretic approach to vagueness, MacFarlane doesn't think that this approach solves the sorites paradox.

5 A recent empirical study by David Ripley (2011) partially bears Smith's claim out. For degree-theoretic treatments of higher-order vagueness see, e.g., Smith (2008, pp. 304–315) and MacFarlane (2010).

6 This sketch of Wright's arguments ignores some subtleties addressed in his 2001. Wright also explores some arguments that don't appeal to (EC). See Wright (2003a, pp. 102–104; 2003b, pp. 472–473).

7 Actually, this is Russell's schema (Priest, 2002, p. 129), which Priest's inclosure schema generalizes. The difference won't matter here.

8 See also Weber (2010), and see Weber *et al.* (2014, p. 813, fn. 1) for some background to Priest's discussion.

9 Curry (1942); see Cook (2013, pp. 71–77) for a more accessible presentation.

10 See Weber *et al.* (2014) for critical discussion of Beall. An alternative unified solution to the paradoxes (potentially including Curry's paradox) involves placing restrictions on the *structural* rules built into classical logic (as opposed to the *operational* rules that govern the various logical constants). For such approaches to the sorites paradox, see, e.g., Ripley (2013) and Zardini (2008).

11 See also Shapiro (2006) (though his treatment of the sorites paradox is rather different to that sketched in the text), and see Keefe (2003) and Greenough (2005) for criticism.

12 For critical discussion of Fara see Stanley (2003, pp. 277–279); but see Fara (2008) for a reply. See also Heck (2003, pp. 119–120).

13 This general worry is critically discussed in Åkerman and Greenough (2010a). Keefe (2007) offers a battery of further arguments against contextualism: see Åkerman and Greenough (2010b) for discussion.

Further Reading

Cook (2013) is an accessible introduction to paradoxes in general, and it includes a chapter on the sorites as well as coverage of many other topics discussed here. Keefe and Smith (1997) is an anthology of now classic papers on vagueness, while Beall (2003) and Dietz and Moruzzi (2010) are collections of recent work on the topic that both include important discussions of all of the issues covered here, as well as several key papers on higher-order vagueness. Important recent monographs on the sorites include Keefe (2000), Sorensen (2001), Shapiro (2006), Smith (2008), and Raffman (2014).

29

Time and Tense

BERIT BROGAARD

1 Introduction

Two of the main debates in philosophy of language concerning time and tense are the debate about the semantics of the tenses in the English language and the debate over whether propositions can be transiently true or false as opposed to always being eternally true or false. The latter quarrel is also known as the 'temporalism–eternalism debate.' Given standard semantics, the two debates are not logically independent, as we will see. Those who believe propositions are eternally true or false needn't treat the tenses as operators. Their opponents, on the other hand, appear to be committed to an operator theory of the tenses, given a standard semantic framework. In this chapter I will focus primarily on these two debates.

There are many other debates about time in philosophy of language. For example, there is a question about how we can best account for the cognitive significance of claims like 'Today is February 5, 2014' or *de se* beliefs such as John's belief that it's 3 o'clock now. On a standard account of propositional content, 'Today is February 5, 2014' expresses the proposition that February 5, 2014 is February 5, 2014. But the latter is trivially true and not something anyone needs to discover empirically. Finding out that today is February 5, 2014, on the other hand, can be an important empirical discovery. If you got married on February 5, knowing that today is February 5, 2014, may help you not getting into trouble with your spouse. John's *de se* belief that it's 3 o'clock now presents its own problems, because this belief clearly isn't the same as the belief that it's 3 o'clock at 3 o'clock. So, beliefs cannot simply be relations to the propositions of standard semantics. Although these other debates about time are interesting, they are not exclusively about time. Accounting for the cognitive significance of claims like 'I am Brit' or *de se* beliefs such as John's belief that he is the shopper who is making a mess, presents the same challenges to standard semantics as the analogous examples involving time. For this reason I shall not deal with these issues except in passing.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

At the end of the chapter I will briefly look at the relevance of debates about tense and eternalism/temporalism to metaphysical debates about time. I will argue that the debates in philosophy of language are not logically independent of the debates in metaphysics.

2 Temporalism versus Eternalism

2.1 Times in Propositions versus Time Neutrality

Mark Richard (1981) calls the thesis that propositions are unable to change their truth-values over time 'eternalism' and the opposing view 'temporalism.' Temporalism is committed to the view that either some propositional attitudes have temporal propositions as their objects or sentences that lack time adverbials (e.g., 'now,' 'when John was born,' 'at 2 p.m. July 6, 2005') express, relative to a context of use, temporal propositions. Propositions of this sort may vary in truth-value over time. For example, the proposition expressed, relative to a context of use, by 'This tree is covered with green leaves' may be true in the summer but false in the winter.

Whether eternalism or temporalism is correct will depend on which of the two views (if any) best accounts for the features that propositions have traditionally been said to have. Traditionally, propositions have been thought to play a number of distinct theoretical roles: Propositions are (i) the semantic values of truth-evaluable sentences, (ii) the objects of the attitudes (e.g., belief, doubt, hope, wish, and so on), (iii) the objects of agreement and disagreement, (iv) what is transferred or shared when people communicate successfully, and (v) the contents intensional operators operate on (e.g., modal operators or tense operators). It may turn out that neither temporalism nor eternalism can ensure that propositions play all of these roles. The verdict (if any) will then depend on which view allows us to preserve most of these roles, or most of the roles that we regard as most important.

One feature that has traditionally been regarded as important is that propositions are the entities that modal operators and tense operators operate on. Taking something like this claim for granted, David Kaplan (1989) has offered a now well-known argument for the view that there are temporal propositions, that is, propositions that are capable of changing their truth-values over time. The argument runs as follows.

Kaplan's Argument
(A) There are non-redundant tense operators in English.
(B) Tense operators operate on propositions.
(C) Tense operators that operate on eternal propositions are semantically redundant.
(D) Hence, tense operators operate on temporal propositions.
(E) Hence, there are temporal propositions.

Kaplan takes premise (A) to be empirically evident. In Kaplan's opinion, premise (B) is relatively innocent as well. It should be said, however, that Kaplan does not insist on the term 'proposition.' In fact, his use of scare quotes reflects his 'feeling that this is not the traditional notion of a proposition' (1989, p. 503). However, the claim that tense operators operate on content rather than, say, linguistic meaning is an important corollary of the theory of Kaplan's "Demonstratives." Premise (C) is the key premise of the argument, as far as Kaplan is concerned. The argument for premise (C) runs as follows. Consider a sentence containing a past tense operator, such as:

(1) It has been that John is a firefighter.

The past tense operator 'it has been that' shifts the time feature of the circumstance of evaluation at which the content of sentence (1) is evaluated from the time of speech to some time in the past. If, however, the content of 'John is a firefighter' were eternal, it would have the same truth-value with respect to any time of evaluation. So 'It has been that John is a firefighter' would have the same truth-value as the operand sentence 'John is a firefighter,' which is to say that 'it has been that' would be semantically redundant. The argument is nicely summarized in this footnote from "Demonstratives":

> Technically, we must note that intensional operators must, if they are not to be vacuous, operate on contents which are neutral with respect to the feature of circumstance the operator is interested in. Thus, for example, if we take the content of S to be [eternal], the application of a temporal operator to such a content would have no effect; the operator would be vacuous. Furthermore, if we do not wish the iteration of such operators to be vacuous, the content of the compound sentence containing the operator must again be neutral with respect to the relevant feature of circumstance. This is not to say that no such operator can have the effect of *fixing* the relevant feature and thus, in effect, rendering subsequent operations vacuous; indexical operators do just this. It is just that this must not be the general situation. A content must be the *kind* of entity that is subject to modification in the feature relevant to the operator. (Kaplan, 1989, pp. 503–504, n. 28)

Intensional operators must operate on contents whose truth-value varies with the feature shifted by the operator. Otherwise, they are semantically redundant. Since the truth-values of eternal propositions do not vary with time, tense operators that operate on eternal propositions are semantically redundant. Hence, if there are non-redundant tense operators in the language, then they operate on temporal propositions.

Premises A and B, however, are not as innocent as they may at first seem. As we will see below, premise A, *viz*. the claim that there are tense operators in the English language, has been disputed by both philosophers and linguists. It is a minority view among linguists today but is still fairly commonly accepted among philosophers. One alternative to the operator view is the quantifier view, defended by, for example, Jeff King (2003). On this view, 'it was the case that it was raining in St Louis' expresses the proposition that there is a time t that is earlier than the time of utterance t^*, and it is raining in St Louis at t. We will return to the debate about the tenses below.

Premise B, *viz*. the claim that tense operators operate on propositions, has also been rejected by several philosophers, including Michael Dummett (1991), Nathan Salmon (1989), and Jason Stanley (1997a; 1997b). Although these thinkers accept that there are tense operators in the English language, they deny that they operate on propositions. They distinguish between the assertoric content and the compositional semantic value of a sentence. Tense operators, they say, operate on the compositional semantic value, whereas assertoric contents serve as the objects of belief and the contents of utterances. Assertoric contents, they say, serve as propositions, whereas compositional semantic values do not serve as propositions. The former are eternally true or false, whereas the latter can take on different truth-values at different times. So, drawing this distinction allows its defenders to advocate for eternalism without having to reject the claim that there are tense operators in the English language. Although the distinction between assertoric content and compositional semantic values is not uncontroversial (see Brogaard, 2012, ch. 6), a knock-down argument against this view has still to be provided. So, Kaplan's argument cannot currently be considered a successful argument for temporalism.

In his dissertation, Clas Weber (2013, ch. 2) has provided a variation on Kaplan's argument that he says avoids the problematic intensional assumptions of Kaplan's argument. He calls this argument 'the substitution argument.' It starts with the observation that for eternalists sentences without an explicit time specification express the same eternal propositions as the sentences in which the time specification is made explicit. So, 'it is raining in Canberra' and 'it is raining in Canberra at t^*,' where t^* is the time of utterance, are semantically equivalent for the eternalist. He calls pairs of sentences of this kind 'eternalization pairs.' Now consider the following eternalization pair:

(2) It is raining in Canberra.
(3) It is raining in Canberra on the 22nd of August 2010 at 2:36 p.m.

Because (2) and (3) are an eternalization pair, they are semantically equivalent as far as the eternalist is concerned. Despite this, (2) and (3) cannot be interchanged *salva veritate* within the temporal construction *It is always the case that*.

(4) It is always the case that it is raining in Canberra.
(5) It is always the case that it is raining in Canberra on the 22nd of August 2010 at 2:36 p.m.

Weber argues that (4) is false, whereas (5) is not. (4) implies that Canberra, like Seattle, always requires you to bring an umbrella when you go out. (5), on the other hand, implies that it is eternally true that it is raining on a particular day in Canberra. Because substitution fails in the temporal context, Weber says, (2) and (3) cannot be semantically equivalent after all. So, eternalism is false.

However, I don't think Weber is right that the substitution argument does not rest on the intensional assumptions of Kaplan's argument. Kaplan's argument relies on, for example, the assumption that there are tense operators in the language (e.g., 'It is always the case that'). So does the substitution argument. It is clear that the argument does make this assumption, otherwise substitution would be illicit for different reasons. For example, substitution of 'it is raining at t_1' for 'it is raining' is illicit in the following context if the tenses are quantifiers rather than operators:

(6) It was the case that it is raining.

If this is analyzed as 'there is a time t such that t is earlier than the time of speech, and it is raining at t,' then substituting 'it is raining at t_1' for 'it is raining' is clearly illicit. The same holds for 'it is always raining.' If this is analyzed as 'for all times t, it is raining at t,' then it is illicit to substitute 'it is raining at t_1' for 'it is raining.' So, the substitution argument does, in fact, rest on the assumption that there are tense operators in the English language. Only these kinds of operators would make the substitution illicit for reasons relevant to the temporalism–eternalism debate.

But if 'it was the case that' is a tense operator, then it is open to defenders of the distinction between assertoric content and compositional semantic values to argue that the reason we cannot embed (2) and (3) within the scope of this temporal operator is that temporal operators operate on compositional semantic values. So, when (2) is embedded under 'it is

always the case that,' then it has a different content than when it is not embedded. This explains why substitution is elicit. The substitution argument thus does not seem to fare better than Kaplan's original argument.

2.2 Richard's Argument

Another well-known argument central to the temporalism–eternalism debate was set forth by Mark Richard (1981). The argument is supposed to show that there are obviously invalid arguments that would come out valid if temporalism were true. So temporalism is false. Here is one such apparently invalid argument:

(A)
Mary believed that Nixon was president.
Mary still believes everything she once believed.
Therefore, Mary believes that Nixon *is* president.

According to Richard, "this argument is not a valid argument in English. As speakers of English use sentences such as [premise 1] and [premise 2], [the conclusion] simply does not follow from them" (1981, p. 4). Or, as Salmon puts it, "such an inference is an insult not only to Mary but also to the logic of English, as it is ordinarily spoken" (1989, p. 345). Yet, says Richard, the temporalist must regard (A) as valid. On behalf of the temporalist, Richard assigns the following metalinguistic truth-conditions to (A):

$$\exists p \exists t(t < t^* \,\&\, p = [P_n] \,\&\, Bmpt)$$
$$\forall p(\exists t(t < t^* \,\&\, Bmpt) \rightarrow Bmpt^*)$$
$$\exists p(p = [P_n] \,\&\, Bmpt^*)$$

(p ranges over propositions, '$<$' means 'is earlier than,' t^* is the time of speech, m is a constant that refers to Mary, and $[P_n]$ is the temporal proposition that Nixon is president). The first premise is true iff there is a time t such that t is earlier than the time of speech t^*, and a proposition p such that p is *Nixon is president* and at t Mary believes that p. The second premise is true iff for all propositions p, if there is a time t that is earlier than the time of speech t^* and Mary believes that p, then at the time of speech t^* Mary believes that p. The conclusion is true iff there is a proposition p such that p is *Nixon is president*, and at the time of speech t^* Mary believes that p. But this is valid. So the temporalist is committed to the validity of an apparently invalid argument.

The eternalist is not so committed. For the eternalist takes the first premise to mean that there is a time t such that t is earlier than the time of speech t^*, and Mary believes at t that Nixon is president *at t*. From this and the assumption that Mary still believes everything she once believed it does not follow that Mary believes at t^* that Nixon is present at t^*. In other words, the difference between the verdicts of temporalism and eternalism is that temporalism takes the objects of beliefs to be temporally neutral, whereas eternalism takes them to be temporally specified.

As I have argued on previous occasions, the main problem with this argument is that there are structurally analogous arguments that seem to us to be valid, which is what temporalism would predict (see, e.g., Brogaard, 2012, ch. 2). Here are a few examples:

(B)
John will be thinking that Mary is hungry.
Everything John will be thinking he is thinking now.
Therefore, John is thinking that Mary is hungry.

(C)
Yesterday John believed that Arnold Schwarzenegger was the president of the United States.
Today John believes whatever he believed yesterday.
Therefore, John believes that Arnold Schwarzenegger is the president of the United States.

(D)
Yesterday John pretended that he was a famous actor.
Now he is pretending that same thing again.
Therefore, John is pretending that he is a famous actor.

(E)
Yesterday John dreamed he was the president of the United States.
Now he is dreaming the same thing as yesterday.
Therefore, John is dreaming that he is the president of the United States.

Unlike eternalism, temporalism correctly predicts that these arguments are valid (the verdict of untutored informants). Although these arguments are structurally analogous to Richard's argument (A), our intuitions differ in these cases. So, our intuitions regarding argument (A) cannot be used to establish that temporalism is false. The temporalist might say that what goes wrong in argument (A) is that the conclusion is so outrageous ('an insult to Mary') that we automatically reject it, despite the fact that it follows from the premises. If the conclusion were less outrageous, perhaps our intuitions would be less strong. We might test that hypothesis by considering the following argument:

(F)
Mary believed that Obama was president.
Mary still believes everything she once believed.
Therefore, Mary believes that Obama *is* president.

Most people asked about the status of this argument seem to think it is perfectly fine, or at least it does not seem obviously invalid to them. So, it may be that argument (A) seems outrageous because the conclusion is outrageous. It is hard to envisage that Mary could be that stupid.

2.3 Belief Retention

Richard (1981) also argues that the temporalist has a problem accounting for belief retention. Consider the following example of belief retention:

(G)
I, Mary, believed that Nixon was up to no good in the White House, and I still believe that.
Therefore, I, Mary, believe that Nixon is up to no good in the White House.

Intuitively, (G) is invalid. Yet, says Richard, the temporalist is committed to its validity. For, given temporalism, the premise is true iff there is a time *t* such that *t* is earlier than the time of speech t^* and Mary believes at *t* that Nixon is up to no good in the White House, and at t^* Mary still believes that Nixon is up to no good in the White House. From this, of course, it follows that at t^* Mary believes that Nixon is up to no good in the White House.

Eternalism, on the other hand, is not committed to this result. According to the eternalist, the objects of the attitudes are eternal. So, the premise is true if and only if there is a time *t* such that *t* is earlier than the time of speech t^* and Mary believes at *t* that Nixon is up to no good in the White House at *t*, and at t^* Mary still believes that Nixon is up to no good in the White House at *t*.

Richard (1981, p. 6) considers the possibility of the temporalist offering an alternative account of belief retention. On this view, "to retain a belief is *not* to continue to believe the very same proposition. Rather, it is to believe a proposition related in some special way to the proposition originally believed" (1981, p. 6). To believe what one once believed is to believe that it was the case that what one once believed obtains. For example, if Mary once believed that Nixon is president, and she retains this belief, then she now believes that Nixon was president. This move would block Richard's argument. For from the assumption that Mary once believed that Nixon is president but now believes that Nixon *was* president, it does not follow that she believes that Nixon *is* president. Richard thinks this account of belief retention is unacceptable.

However, as it turns out, (G) is not a good way of refuting temporalism for the same reason that (A) is not a good way to refute temporalism. It may simply be that we find Mary's claim that she believes that Nixon is still in the White House so stupid that we implicitly reject the entire reasoning process, in spite of it being valid.

What Richard does not realize is that it is a much greater challenge to come up with an adequate account of how belief is retained over time if the objects of belief are eternal propositions. The problem for the eternalist is that we rarely retain belief for the long term by remembering the same eternal proposition. Presumably, when we store a belief about a present occurrence, we store it as a past-tensed proposition. For example, if at 15:13 on January 5, 2010, I see a red car leave a crime scene, I will likely store the information as a past-tensed proposition; for example, I may store the information in the form *it was the case on that day where I observed the horrible crime that a red car left the crime scene*.

Because eternalists are committed to the claim that all propositions make reference to a time, they cannot account for this way of storing information. They might say that the information I store has the form 'there is a time *t* such that *t* is prior to or identical to t^*, and Brit observes a terrible crime just before *t* and a red car is leaving the crime scene at *t*,' where 't^*' refers to the time at which the belief information is stored, for example, 15:13 on January 5, 2010. But surely this is not the kind of information that is likely to get stored. To store this kind of information the brain would need to be in a position to track the time precisely at the time of storage. It is just plainly implausible that the brain would have tracking powers like that. If, on the other hand, the brain stores a temporal proposition, then belief retention consists in continuing to stand in the belief relation to the same temporal proposition. So, eternalism is false.

The eternalist may insist that they have a way of dealing with this sort of case. What I store in my hippocampus is not a proposition that refers to a specific time but rather a proposition that quantifies over times. I observe the crime and see the red car escape and then I form the belief that there is a time *t* such that Brit observes a terrible crime just before

t and sees a red car escape at *t*. While this gets around the problem of how the brain stores information about specific times on the basis of observations of a scene with no clocks, it runs into trouble of a different kind. When I retrieve the stored information, my retrieved memory can be true even if I never observed a crime in my life. It could be true if I were to observe a red car escape a crime scene 10 years from now. Our ordinary life experiences tell us that it is unlikely that I falsely remember the details about an event that then occurs in the same way 10 years later. But memories need not be very detailed. If I am told at time *t* that I got an A for my essay about Columbus, this may be all I am able to recall later about the situation in which I learned this fact and about the essay. But if my brain stores the information that there is a time at which I get an A for my essay about Columbus, then what I recall could be true, even if the only essay I ever wrote about American history was about Lewis and Clark. It would be true if I were to go back to school later and were to earn an A for my essay about Columbus. Belief information clearly is not stored in memory in this kind of tense-neutral way. Information about the past is stored for the long term in a past-oriented way.

We don't always continue to believe a proposition by storing the information in storage memory. Sometimes I continue to believe something over time without storing the information in storage memory at all. This is the case when we keep information available in working memory. For example, if I want to call you, I may look up your phone number in the phonebook. As phone books are reliable sources of information, I rationally come to believe that your phone number is, say, 283-1759. I can keep this information available in working memory for the few minutes it takes me to find my phone and dial the number. The information I keep available in working memory for the few minutes it takes me to find my phone and dial the number is hardly indexed to a specific time. I don't continue to believe that your number is 283-1759 by believing that your number is 283-1759 at 15:00 on July 5, 2010, that your number is 283-1759 at 15:01 on July 5, 2010, and so on. The information I keep in mind is just the non-indexed information that your phone number is 283-1759. For as long as I keep that information available in my mind, I stand in a belief relation to the information. So, it is possible to stand in a belief relation to temporal content. This is in conflict with eternalism.

In general, it seems that information can be retained over time in two different ways. One can retain it in the past tense, or in the present tense. Information about occurrences typically is stored in the past tense, whereas information about things that continue to exist over time may be stored in the present tense. When I saw the red car leave the crime scene, that's an occurrence, and the information is therefore stored in the past tense together with some temporal markers. Since phone numbers exist over time and do not change very quickly, information about phone numbers may be stored as a present-tensed proposition that does not make reference to a time.

The duality in how we retain belief is reflected in the language we use to talk about it. If I say "Four years ago I believed that John was a firefighter, and I still believe it," then I can either mean that I still believe that John is a firefighter or that I still believe that he was a firefighter then. But the standard version of eternalism cannot account for the duality in the meaning of these sentences. The standard version is required to interpret the second clause as being a time-indexed claim about John four years ago. At best this captures the second reading. The other reading is unaccounted for.

The following examples shed further light on the difficulty that the duality in the meaning of these sentences presents for eternalism (Brogaard, 2012, ch. 2):

DECEIT

WIFE: When I married John I thought he was a police officer. Thirty years later I still believed he was a police officer. Turns out that he was fired two years into our marriage.

LOST LOVE

FRIEND: Yes, Barbara did love you 10 years ago. So you were right back then. But you still believe that she loves you, don't you Peter?

DEFENSE

STUDENT: I think my dissertation is done.

SUPERVISOR: You do? Well, I think you are wrong. Work on it for a few more weeks. Then read it again. If you *still* think that it's done, then we'll talk.

It is important to note here that these cases are about still believing that something is the case rather than believing that something still is the case. So, in LOST LOVE, for example, the friend claims that Peter still believes that Barbara loves him. The latter claim is distinct from the claim that Peter believes that Barbara still loves him. The two claims may be closely related but it is the former construction I am interested in here.

Eternalism holds that what we believe when we believe something that is not in the past tense is a time-indexed proposition. So, in the envisaged example outlined in DECEIT, the wife's original belief has the propositional content *my husband is a police officer at t*, where *t* is some time 30 years ago. If 'still believes' requires the content of the beliefs be the same, then the propositional content of the wife's belief after 30 years is *My husband is a police officer at t*.

Likewise, in the envisaged example outlined in LOST LOVE, Peter's original belief has the propositional content *Barbara loves me at t*, where *t* is some time 10 years ago. If 'still believes' requires the content of the beliefs be the same, then the propositional content of Peter's belief after 10 years is *Barbara loves me at t*.

Finally, in the envisaged example outlined in DEFENSE, the supervisor's original belief has the propositional content *S's dissertation is done at t*, where *t* is the time of the student and her supervisor's exchange. If 'still believes' requires the content of the beliefs to be the same, then the propositional content of the advisor's belief a few weeks later is *If you still think that it's done at t, then we'll talk*.

But it is hardly the case that the wife in DECEIT means that she still believes the same time-indexed proposition after 30 years, *viz*. the proposition *my husband is a police officer at t*, where *t* is some time 30 years ago, that the friend in LOST LOVE means that Peter still believes the proposition *Barbara loves me at t*, where *t* is some time 10 years ago, or that the supervisor in DEFENSE is asking *S* to return if *S* still believes the proposition *S's dissertation is done at t*, where *t* is the time of their exchange. To my mind, such cases raise one of the most pressing kinds of problems for eternalism.

2.4 Arguments from Disagreement

Eternalism holds that present-tensed sentences make implicit reference to the time of speech. 'John is a firefighter,' for example, expresses, relative to a context, the proposition that John is a firefighter at t^*, where t^* is the time of speech. But once we insist that the

contents of our utterances refer to a fixed time, it becomes difficult to see how we can have proper agreements and disagreements over extended time periods. So, successful communication over time must at least sometimes involve temporal contents. Or so I will argue.

The style of argumentation here is similar to the one used by relativists and non-indexical contextualists to refute more general forms of contextualism. This style of argumentation has received its fair share of criticism most recently in Herman Cappelen and John Hawthorne's (2009) *Relativism and Monadic Truth*. This is not the place to engage in the broader debate about whether this form of argumentation can be successfully employed in a refutation of indexical contextualism. Here I will just look at the localized case of eternalism. I reply to Cappelen and Hawthorne's criticisms pertaining to this localized case below.

One way in which arguments from disagreement presented against eternalism differ from arguments from disagreement presented against indexical contextualism more generally is that the former arguments are specifically directed at the claim that all tensed propositions make reference to specific times. But conversations take place over extended periods of time, and most of these conversations are not about specific times in the recent or not so recent past but about some other subject-matter altogether. Specific times may be completely irrelevant to what is discussed. So, it seems that the information that is passed on and that is the subject of discussion in many cases is temporally neutral. It should therefore not come as a surprise if conversations that take place over time become real challenges for eternalism even if they provide no real problem for broader indexical contextualist theories.

To see why the eternalist may have trouble accounting for how information is passed on in ordinary conversations, consider the following exchange:

FIRED FIREFIGHTER
(A and B are talking on the phone. B is standing outside the door of an office where a conversation is taking place between John and his superior).
A: … John is a firefighter.
(Behind closed door the superior is shouting: "you are fired!")
B: I guess you are right. But John is not a firefighter. He was just fired.

The discourse fragment is supposed to sound odd. If you don't have that intuition, the argument does not even get off the ground. However, most people seem to have the intuition that the discourse fragment sounds odd. But let us look now at the predictions yielded by a standard version of eternalism that takes propositions to make reference to a specific time. On such a version of eternalism, A says that John is a firefighter at t_1, and B then replies that A is right but adds that John is not a firefighter at t_2. Notice that there is nothing wrong with the translation I just provided. It doesn't sound odd at all, and for good reasons. If A said that John is a firefighter at t_1, then we should expect B's reply to be acceptable. For it is still true at t_2 that John is a firefighter at t_1.

However, in the envisaged scenario, it would make much more sense for B to have replied: "No, you are wrong. I am standing outside the superior's office, and the superior just told him that he was fired."

Note that this argument, as formulated, does not rest on any intuition about whether A asserts a proposition denied by B. Rather, the argument rests on the oddity of the discourse fragment together with a version of eternalism that takes propositions to make reference to specific times. In other words, if FIRED FIREFIGHTER sounds odd, but the eternalist translation does not, then the eternalist translation is likely mistaken.

Tsompanidis (2013) raises several objections to this type of argument, which I presented in *Transient Truths* (Brogaard, 2012). I will briefly review what I consider his main objection to this type of argument. He argues that the eternalist could turn to interval semantics to account for agreement and disagreement. For example, 'John is a firefighter' might mean 'John is a firefighter *at least up to* and *including* the time of *the entire conversation*.' This type of account may be able to explain what is wrong with dialogues like the one presented in FIRED FIREFIGHTER. As Tsompanidis notes, I *do* consider this kind of reply at length in the book but let me address the specific account he proposes. One major problem for defenders of this type of proposal is to give precise truth-conditions for sentences, given that conversations do not have clear boundaries. A further, related, problem is that the time of the entire conversation cannot always serve as a reference time. Consider the following sentences:

(7)
(a) Mary is falling down from the tree
(b) Afghanistan is at war
(c) I am alive.

If (7a) is uttered during an extended conversation that may continue for hours while Mary is taken to the hospital, the relevant time interval cannot be one that includes the entire conversation. In this case, it may be suggested that the time interval is determined by the duration of the event. However, this suggestion cannot be right. I might utter (7a) because I believe that Mary is falling down from the tree, even though she is not. In that case, there is no event to determine the relevant time interval. While there are many other proposals that could be considered, the sentences in (7a–c) suggest that it will be difficult to give a systematic account of the time intervals that the present tense is supposed to make reference to. Though I agree with Tsompanidis that there are very many points that need to be settled about how language makes reference to time, I think that the problems the eternalist encounters with respect to agreement and disagreement give us a strong reason to prefer temporalism to eternalism.

In their monograph *Relativism and Monadic Truth* Cappelen and Hawthorne provide evidence against disagreement data and argue that the best test for whether an expression is context-sensitive or not is one that gives "center stage to the verbs 'agree' and 'disagree'" (2009, p. 54). The test can be illustrated by means of an example. If A says 'Mary has had enough. She has had three slices of cakes' and B says 'Mary has had enough. She is going to leave her husband,' then we cannot correctly infer 'A and B agree that Mary has had enough.' The oddity of the agreement report is supposed to show that 'had enough' is context sensitive. It has different meanings in different contexts.

The reason the test works as a true test of shared content, Cappelen and Hawthorne say, is that it is hard to hear 'agree' in agreement reports as distributive. Cappelen and Hawthorne then argue that the test shows that propositions are not temporally neutral. Here is one of their examples. John says 'Bill has died' in response to the question 'Why did Bill not show up at the pub last week?' And Janet says 'Bill hasn't died' in answer to the question 'Why did Bill's children not get their inheritance last year?' They conclude that "The claim 'Janet and John disagreed about whether Bill had died' is clearly infelicitous" (2009, p. 98).

However, Cappelen and Hawthorne's test fails. For disagreement to take place it is not sufficient that one speaker denies something that another speaker asserts. Interesting

disagreement requires that there is a time at which two speakers are, or pretend to be, in the same conversational context and are prepared to assign different truth-values to the same content.[1] In the envisaged scenario, John and Janet are not, and do not pretend to be, in the same conversational context. So, they don't disagree in any interesting sense. Hence, the disagreement report is false.

Consider the following modified example: John and Janet are having a dispute about whether Bill has died. John says: 'Bill has died. He didn't show up at the pub last week.' Janet replies: 'No, Bill hasn't died. His children didn't get their inheritance.' Given this conversational context, the disagreement report 'Janet and John disagree about whether Bill has died' comes out true.

Cappelen and Hawthorne argue that 'debated' has the same properties as 'agree' and is equally suitable for testing for context sensitivity (2009, p. 57). Substituting 'debated' for 'agreed,' however, gives us the same results. 'Janet and John debated whether Bill had died' is false in the first case and true in the second.

To further see that the disagreement test fails, consider the following example. John says 'Bill died at 2 p.m., December 11, 2010 EST' in response to his drinking buddy's question 'Why did Bill not show up at the pub last week?' And Janet says 'Bill didn't die at 2 p.m., December 11, 2010 EST' in response to her husband's question 'Why didn't Susan win the bet?' Here the claim 'Janet and John disagreed about/debated whether Bill died at 2 p.m., December 11, 2010 EST' is clearly false, despite the fact that Janet denies what Bill asserts. This becomes even more apparent if we make the innocent move of substituting 'had a disagreement about' for 'disagreed about.' Janet and John did not have a disagreement about anything. But we cannot take that to mean that 'Bill died at 2 p.m., December 11, 2010 EST' has different meanings in different contexts.

2.5 Temporalism and the Problem of Intentionality

The arguments provided above give us some reason to favor temporalism over eternalism but the most compelling argument, in my opinion, turns on the problem of intentionality. The problem of intentionality is that of explaining how a set or a mereological sum of objects and properties comes to represent anything. How does a set of individuals and properties come to have intentional properties? This is a problem that goes back at least to Frege and the early Russell. It is also sometimes misleadingly known as the 'problem of the unity of the proposition.' Recently, several philosophers of language have argued that the problem cannot be cracked if we keep treating sets of individuals and properties as the entities that do the representational work (see, e.g., Soames, 2013; Brogaard, 2014). Although we still need to figure out what '(conscious) representation' means, a first step in the right direction is to realize that intentionality is first and foremost a property of cognitive states. What is called a 'proposition' (or a 'content') is best understood as a kind of generalization based on token cognitive states. We can take propositions to be types of cognitive acts, an act of predicating involved in perceptual states, belief states, agreements, and so on. Propositions thus have representational properties only in a derivative sense. They themselves are generalizations based on token cognitive states. It's the token cognitive states that are the primary bearers of intentional properties.

But, now, not all token mental states represent times. Here is a counter-example to the assumption that all mental states represent times. Mary is pregnant on December 24, 2014, and is expected to give birth on January 15, 2015. But on the morning of December 24,

2014, John and Mary are in a car accident. Mary and the baby are fine. But John is in a coma. Exactly four months later John wakes up and remembers the accident, up to his losing consciousness. He believes it is still December, 2014, and says: 'Where is Mary? She is pregnant.' It is reasonable to think that John really believes that Mary is pregnant. But it just isn't true that John believes on April 24, 2015, that Mary is pregnant on April 24, 2015. He knows human pregnancy cannot take 12 months. He believes Mary is pregnant because he believes it's still December, 2014. So, John's belief that Mary is pregnant cannot plausibly be taken to represent that Mary is pregnant on April 24, 2015. A more plausible suggestion is that John believes in a temporally neutral way that Mary is pregnant. Cases like this give us good reason to think that not all mental states represent times.

If cases like this one aren't sufficiently convincing, we can turn to the case of perception. Perceptual experience does not seem to represent times. You can perceive the same visual scene at 1:01 p.m. and at 1:02 p.m. without the phenomenology of your visual experience having changed one bit. So, the phenomenology of visual experience does not always represent times, which is to say that not all acts of predicating represent a time. But propositions are generalizations from acts of predicating involved in perception, belief, and wishing, and so on. We generalize away differences. As not all acts of predicating represent times, propositions do not in general represent times. But if they do not, then eternalism is false.

3 The Quantifier View versus the Operator View

3.1 Evidence against the Operator View

As we saw above, Kaplan's argument for temporalism rests on the premise that there are tense operators in the English language. This makes the debate about tenses directly relevant to the debate about temporalism versus eternalism. But there are other reasons to consider the two debates logically interconnected. Though temporalism is not articulated as a view about how to treat the tenses in English, on the most natural understanding of temporalism, the debate between temporalism and eternalism is not orthogonal to the debate about how to treat the tenses. Standard versions of eternalism require that the time of speech is a constituent of all propositions. As the time of speech is variable, sentences that express eternal propositions must have a hidden variable in the sentence structure that takes times of speech as its values. This type of sentence structure follows as a natural consequence of a treatment of the tenses as quantifiers. Where t^* is the time of speech, 'John is a firefighter' is of the form 'John is firefighter at t^*,' 'John was a firefighter' is of the form 'there is a time t such that t is earlier than t^*, and John is a firefighter at t,' and 'John will be a firefighter' is of the form 'there is a time t such that t is later than t^*, and John is a firefighter at t.'

Temporalism, by contrast, must treat the tenses as sentential operators, at least given standard semantics. It may be thought that it is possible to combine temporalism with a quantificational account of the tenses. For example, it may be thought that 'John was a firefighter' could be treated as having the following underlying form:

(8) $\exists t(t < t_n$ & John is a firefighter at $t)$,

where t_n is an unarticulated constituent that takes different values across time. If (8) expresses a proposition with an unbound variable, then that proposition will have different

truth-values at different times. The problem with this view is that a content that contains an unbound variable isn't a complete proposition, given standard semantics. In standard semantics, sentences, relative to context, express complete propositions that do not require further satisfaction by context. So, unless we adopt some special semantics, (8) expresses an eternal proposition, *viz*. the proposition that results from substituting the time of speech for t_n. It thus seems that within a fairly standard semantic framework, temporalism is committed to a treatment of the tenses as sentential operators, whereas eternalism is committed to a treatment of the tenses as quantifiers over times or some similar view (e.g., a treatment of the tenses as quantifiers over events or as discourse variables).

The problem for the temporalist is that a wide range of empirical evidence suggests that the tenses function as quantifiers (or perhaps variables) and not as circumstance-shifting operators. I cannot cover the full range of evidence here. But a few illustrative examples are in order. King (2003) offers three main pieces of evidence to motivate a shift from the operator view to the quantifier approach. One consideration against the standard treatment is that it gives us the wrong truth-conditions for sentences with time adverbials. Consider, for instance (King 2003, p. 216; Dowty, 1982, p. 23):

(9) Yesterday, John turned off the stove.

According to King, traditional tense logic would treat (9) as featuring two operators, namely the simple past tense (P), and 'yesterday' (Y). Y shifts the time of speech to some time yesterday, and P shifts the time of speech t^* to some time t such that t is earlier than t^*. Since (9) contains two operators, says King, it should have the following two readings:

(9)
(a) Y(P(John turns off the stove))
(b) P(Y(John turns off the stove)).

(9a) says that the day before some time in the past John turned off the stove, whereas (9b) says that John turned off the stove some time before yesterday. But (9a) and (9b) do not give us the correct readings for (9). (9a) is true just in case John turns off the stove the day preceding some past time, and (9b) is true just in case John turns off the stove at some time past of yesterday. So (9a) and (9b) may both be true if John turned off the stove 10 days ago; but (9) would be false. Thus, a traditional tense logic yields the wrong truth-conditions for sentences like (9). King's quantificational analysis makes the correct predictions. On King's analysis, (9) cashes out to: 'there is a past time t such that t was some time yesterday and John turns off the stove at t.'

A second reason King offers against a treatment of the tenses as sentential operators is that it would make the wrong predictions in cases like the following (2003, p. 217):

(10) Sheila had a party last Friday, and Sam got drunk.

As Barbara Partee (2004) has made vivid, the English tenses can be anaphoric on other tenses in much the same way that pronouns can be anaphoric on quantifiers or terms. The idea is that (10) is similar in important respects to:

(11) Sam took the car yesterday, and Sheila took it today.

In the case of (11), the pronoun 'it' in the second clause is anaphoric on 'the car' in the first sentence. On one theory of unbound anaphora, defended by Stephen Neale (1990) and others, unbound anaphoric pronouns go proxy for definite descriptions recoverable from the antecedent clause. The 'it' in 'Sheila took it today,' for example, goes proxy for the definite description 'the car Sam took yesterday.' Likewise, in (10) the past tense of the first clause picks out a time interval that is supposed to fall within the time interval picked out by 'last Friday.' The past tense of the second clause is anaphoric on the interval picked out by the past tense of the first sentence. The second clause is thus interpreted as meaning that Sam got drunk at Sheila's party last Friday.

The problem for theories that treat the tenses as sentential operators is that if 'last Friday' in (10) and the past tense of the first clause are treated as independent operators, then the second conjunct in (10) receives the implausible interpretation that Sam got drunk at some time in the past, which – if Sam is like most of us – is obviously true. Again, a treatment of the tenses as sentential operators seems to yield the wrong truth-conditions.

According to King, a more debilitating problem for theories that treat the tenses as operators is that they are unable to give a convincing account of Kamp/Vlach sentences such as:

(12)
(a) One day, all persons alive now will be dead
(b) Once all persons alive then would be dead.

The problem that such sentences present is that they have no satisfactory paraphrase using only the resources of traditional tense logic. In traditional tense logic the future tense operator (F), when unembedded, shifts the time of evaluation from the present time to some time in the future. Anything that occurs within the scope of the future tense operator is evaluated with respect to that time, which makes it difficult to translate (12a). (12b) presents a different problem. The problem here is that the past evaluation time is lost when the future evaluation time is introduced. To translate (12a) and (12b), King says, we need to introduce something like Hans Kamp's (1971) doubly indexed N operator, and Frank Vlach's (1973) doubly indexed K operator, which requires a rather complicated and undesirable semantics.

3.2 Complex Tense Operators

In previous work I have responded to the first two pieces of evidence by introducing complex tense operators (see, e.g., Brogaard, 2012, ch. 4). Complex tense operators are complexes of basic tense operators and time adverbials. The time adverbial needn't be explicitly mentioned but may be implicitly assumed in the context.

King argued that one apparent problem with a treatment of the tenses as tense operators is that it gives us the wrong truth-conditions for sentences with time adverbials. This problem goes away, however, if we allow the tenses to interact with time adverbials, as in 'it was the case yesterday.' If we allow complex tense operators in the semantics, we can provide the following paraphrase of (9):

(9*) It was the case yesterday (that John turns off the stove).

'It was the case yesterday' functions as a circumstance-shifting operator that maps *John turns off the stove* to the true iff *John turns off the stove* is true at a past circumstance of evaluation whose time feature belongs to the class of times picked out by 'yesterday.' Of course, English requires that the embedded clause in (9*) occurs in the past tense. So, in ordinary English, (9) should be paraphrased as 'It was the case yesterday that John turned off the stove.' On the relevant reading, the past tense of the embedded clause is vacuous. There is also an alternative reading where the past tense of the embedded clause is not vacuous. For example, if John turned off the stove the day before yesterday, we can truthfully utter the sentence 'It was the case yesterday that John turned off the stove two days ago.'

Related considerations help to address cases where the tense of one clause is anaphoric on the tense of a preceding clause, repeated from above:

(10) Sheila had a party last Friday, and Sam got drunk.

Here the past tense of the first sentence picks out a time interval that falls within the time interval picked out by 'last Friday.' The past tense of the second clause is anaphoric on the interval picked out by the past tense of the first clause. Two key cases cited as evidence against the operator account thus turn out not to present a threat to the account.

3.3 Montague Grammar

That still leaves us with Kamp/Vlach sentences. Such sentences, it turns out, can be dealt with satisfactorily in Montague grammar (PTQ – proper treatment of quantification in ordinary English; Montague, 1973), which is a tense logic. Consider:

(13) A colleague of mine who was a child prodigy got her PhD from Harvard.

It is tempting to think that we can get the following reading with nested clauses: '$\exists x$(colleague x & P(get PhD x & P(prodigy x))).' On this reading, (13) says that there is someone who is currently at colleague who got her PhD from Harvard at some point in the past and who was a child prodigy before that. Unfortunately, this reading cannot be yielded compositionally.

Compositionality requires that a meaning is yielded for the noun phrase 'A colleague of mine who was a child prodigy,' and that this meaning is then combined with the meaning of 'got a PhD from Harvard.' So, given a compositional interpretation of English syntax (with the exception that noun phrases can scope out), it is not possible for the past tense in 'was a child prodigy' to have wider scope than 'colleague of mine.'

The reason that a meaning is yielded for the whole noun phrase 'A colleague of mine who was a child prodigy' is that within the whole noun phrase 'A colleague of mine who was a child prodigy,' the relative clause is a self-contained syntactic constituent. This constituent has the syntax of a full sentence except that it lacks a noun phrase. Instead of a noun phrase it has a variable that is bound by the noun phrase. So, the relative clause is of the form 'x who was a child prodigy,' where the variable 'x' is bound by 'a colleague of mine.' The compositional structure of 'A colleague of mine who was a child prodigy' is as follows. 'A colleague of mine who was a child prodigy' is composed of the indefinite article 'a' and the noun phrase 'colleague of mine who was a child prodigy.' The latter is composed of 'colleague of mine' and 'who was a child prodigy,' which in turn is composed of 'who' and 'x

was a child prodigy.' Finally, '*x* was a child prodigy' is composed of the past tense morpheme and '*x* is a child prodigy.'

As PTQ observes compositionality (with the exception of the 'quantifying in' rule), it yields the following readings for (13):

(13) A colleague of mine who was a child prodigy got her PhD from Harvard.
(13a) $\exists x$(colleague x & P(prodigy x) & P(get PhD x))
(13b) P($\exists x$(colleague x & P(prodigy x) & get PhD x))

(13a) translates as 'some colleague is such that it was the case that she is a prodigy, and it was the case that she gets her PhD' and (13b) translates as 'it was the case that some colleague, who was a prodigy, gets her PhD.' In (13a) there is quantifying in: the whole noun phrase 'A colleague of mine who was a child prodigy' has wider scope than the main clause, in (13b) there is no quantifying in. So the whole noun phrase 'A colleague of mine who was a child prodigy' has scope under the tense of the main clause.

Dan Zeman (2013) has responded to these sorts of strategies that the temporalist might offer to preserve a fairly traditional tense logic that while the temporalist no doubt can come up with an operator account of the tenses that can accommodate most, if not all, of the phenomena that normally are cited in support of the quantificational account, true supporters of temporalism might want "positive, decisive arguments for the view that tenses are to be interpreted as circumstance-shifting sentential operators, rather than, say, quantifiers over temporal variables verbs come endowed with" (Zeman, 2013, p. 325).

I agree with Zeman that there are very few empirical data concerning the semantics of tense that cannot be accommodated by both operator accounts and quantificational theories of the tenses (as well as many other theories of the tenses). I also agree that debates about the tenses are not going to settle the debate about temporalism. Rather, what is ultimately going to settle the debate between temporalism and eternalism is an argument that is independent of how we treat the tenses in the English language. If the debate can be settled in favor of temporalism, as I have argued above, that gives us good reasons for revisiting an operator theory of the tenses.

4 From Philosophy of Language to Metaphysics

4.1 The Incompatibility of Presentism and Semantic Eternalism

I will now turn to the important question of whether the debate about temporalism versus eternalism has any bearing on the debate about presentism versus metaphysical eternalism. In *Transient Truths* (2012) I argue that the answer is 'yes.' Semantic eternalism, for example, appears to be inconsistent with presentism, a particular version of the A-theory. The argument is this. Presentism holds that only present things exist. But according to the standard version of semantic eternalism, all propositions include a timestamp (e.g., the sentence 'Mary is hungry' may express the proposition that Mary is hungry at 2:05 p.m. on October 1, 2013 EST). Most of these timestamps are past and future times. So, if presentism is true, then the vast majority of these propositions do not exist. The presentist could construe times as ersatz times (sets of propositions) (Brogaard, 2013). But on pain of circularity, this requires granting that there are temporal propositions (without a timestamp). So, presentism is at odds with semantic eternalism.

Giuliano Torrengo (2013) has replied that the book's argument doesn't work, because temporalism is consistent with there being some eternal propositions, for example, the propositions that there are wholly past objects and that I am giving a talk at Stanford University on May 15. Yet, Torrengo argues, "it is the thesis that *some* eternal propositions exist that is at odds with presentism" (Torrengo, 2013, p. 316). This is a nice point. However, I disagree with Torrengo that presentism is at odds with the thesis that there are *some* eternal propositions. As Torrengo himself points out, it is the stronger view that there are *no* temporal propositions (i.e., semantic eternalism) that prevents the presentists from construing times as ersatz times. The weaker view defended in *Transient Truths* (i.e., temporalism) leaves us with all the resources (i.e., temporal propositions) needed to construe times as sets of propositions non-circularly.

That said, Torrengo is perfectly right that if presentism is true, then the temporalist cannot accept all of the eternal propositions ordinary language appears to commit us to. Some temporalists (myself included) argue (while bracketing metaphysical issues) that there are eternal propositions that make explicit reference to times, for instance, the proposition that I am giving a talk at Stanford on May 15. If presentism is true, then that proposition does not currently exist. Presentists must, therefore, reject the existence of these kinds of propositions. (They can, of course, accept the existence of metaphysical propositions such as *there are wholly past objects*, as these types of propositions do not have times as constituents.) The thought that sentences, such as 'I am giving a talk at Stanford on May 15,' do not express a proposition at all and therefore are false is not entirely unmotivated. It could be argued that while an utterance of the sentence 'I am giving a talk at Stanford on May 15' may seem true, this kind of speech is, in fact, idiomatic much like 'the sun is rising.' Idiomatic speech is literally false (or untrue) but conveys something true.

4.2 The Incompatibility of Metaphysical Eternalism and the Quantifier Theory of the Tenses

How we treat the tenses also seems to have metaphysical implications. There is some reason to think that if metaphysical eternalists adopt the quantifier account of the tenses (that is, the semantic eternalist's common account of the tenses), then they will have difficulties making certain metaphysical claims (Brogaard, 2012, ch. 7). The gist of the argument runs as follows. The metaphysical eternalist wants to say that past and future objects exist *simpliciter*. Consider:

(14) Socrates exists.

According to the metaphysical eternalist, Socrates existed in the past but does not presently exist. So, the metaphysical eternalist holds that (14) is true on one reading but false on another. Now combine metaphysical eternalism with the quantifier account of the tenses. On the quantifier account, all propositions are indexed to a time. So, where t^* is the time of speech, (14) is equivalent to the proposition expressed by (15):

(15) Socrates exists at t^*.

But here is the problem. If (15) specifies a false proposition expressed by (14), then what is the nature of the true proposition expressed by (14), according to the metaphysical eternalist?

Torrengo has replied to this sort of argument that "once we accept the distinction between a temporally restricted and a temporally unrestricted reading of quantification (and something analogous for predication), the worry is spurious" (Torrengo, 2013, p. 318). However, this misses the point of the argument. The argument is that if the metaphysical eternalist accepts a quantificational account of the tenses, then she cannot account for the unrestricted reading of (14). (14) can, of course, be read as follows (as Torrengo suggests):

(16) $\exists x(x = \text{Socrates})$, where the domain of values is temporally unrestricted.
(17) $\exists x(x = \text{Socrates})$, where the domain of values is restricted to the present.

According to the metaphysical eternalist, (16) then is true and (17) false. However, this proposal is compatible with a version of temporalism that utilizes quantifier restriction. My own proposal was similar. On the view I prefer, (14) has a reading that determines a function from worlds to extensions and another reading that determines a function from world-time pairs to extensions. The first reading is the 'unrestricted' reading, whereas the second is the 'restricted' reading.

Notice, however, that neither of these proposals utilizes a quantifier account of the tenses. In fact, they are inconsistent with the standard version of semantic eternalism, which requires that all propositions are indexed to a time. And that was just the point of the argument, which was not an argument against metaphysical eternalism but one in favor of temporalism (on the assumption that metaphysical eternalism is true).

A second worry that Torrengo raises is that the presentist cannot claim that (14) is false, on an unrestricted reading. The reason for this, he says, is that I hold that an eternal proposition such as *Socrates exists* is "evaluable as true or false *simpliciter* only in a context in which either Socrates is an instantaneous object, or Socrates always (or never) exists" (2013, p. 318). However, this is not my view. What I said was:

> I think that one *could* use 'John has a straight shape' to mean the eternal proposition that John has a straight shape. But such an eternal claim is truth-evaluable at a world *w* only if (i) John is an instantaneous object at *w*, (ii) John always has a straight shape at *w*, (iii) John never has a straight shape at *w*, or (iv) Lewis is right that the *eternal* proposition *John has a straight shape* is true at *w* iff John has a temporal part that has a straight shape. (Brogaard, 2012, p. 150)

I made this remark in the context of discussing Lewis's problem of temporary intrinsics. The reason 'John has a straight shape' cannot be evaluated except under these conditions is that if John sometimes has a straight shape and sometimes has a bent shape, then relative to the world as a whole the proposition is neither true nor false (or both true and false). The same point does not apply to the proposition that Socrates exists (as existence does not come and go).

A third concern that Torrengo raises also concerns the unrestricted reading of sentences like (14). He argues that my view implies that the unrestricted readings of sentences are never true for the presentist, not even when the entity in question is present. This has the consequence, he says, that "the presentist and the eternalist necessarily disagree on what *presently* exists" (Torrengo, 2013, p. 320), which seems odd.

I agree with Torrengo that that would be odd. However, I don't think the temporalist is committed to this view. Consider:

(18) Obama exists.

If presentism is true, then (18) is true when read restrictedly and unrestrictedly. On the restricted reading, 'Obama' determines a function from world-time pairs to extensions. Since the extension is non-empty, (18) is true on this reading. On the unrestricted reading, 'Obama' determines a function from worlds to extensions. Since this extension is also non-empty, (18) is true on this reading. Torrengo thinks I cannot say this, because I argue that on the unrestricted reading, (18) entails that it will be the case that Obama exists. However, even if we bracket Obama's future existence, there is no problem here, because this kind of tensed sentence is innocuous. It is the result of affixing a tense operator to a sentence given an unrestricted reading. But when tense operators are affixed to an operand sentence that expresses an eternal proposition, the tense operators will be redundant (Brogaard, 2012, p. 150). So, the presentist can agree with the metaphysical eternalist that (18) is true on both its restricted and its unrestricted reading.

Torrengo is right that if the presentist holds that Obama is not fully present but is unfolding in time, then it would seem that she should reject (18). After all, if only some of Obama's parts exist, how could (18) be literally true? I think this is a genuine puzzle but not one that is specifically about the unrestricted reading of (18). It appears to be equally problematic on the restricted (ordinary) reading of (18). The puzzle is not a consequence of accepting presentism or temporalism. Anyone who holds that ordinary material objects are four-dimensional space–time worms needs a way to talk about the properties the present parts instantiate. This is a familiar issue from the metaphysical literature (see, e.g., Sider, 2001). It is true that Obama is speaking even if it's only his present part that is speaking. Yet how can this be if he is extended four-dimensionally? One standard reply is that proper names ordinarily refer only to stages of objects. Whether this is the best reply to the worry is not something I can address here. But let me point out that most three-dimensionalists who take ordinary material objects to endure are faced with a version of this problem. It is commonly agreed upon that events perdure: they have temporal parts located at different times. Yet even if a soccer match takes a considerable amount of time, it can nonetheless still be true to say that you are currently watching one. So, the problem of how to correctly predicate properties of four-dimensional entities may arise regardless of one's particular view of how ordinary material objects persist through time.

4.3 The Passage View and Monadic Truth

As argued above, presentism necessitates the existence of temporal propositions. In reply to my arguments John Hawthorne (2013) has argued that the need for the index of evaluation to contain a time parameter goes away if one accepts what we might call 'the passage view.' Unlike presentism, which holds that only present things exist, the passage view holds that future and past things exist but that they have a different status compared to presently existing things. One option is to treat past and future objects as abstract and present objects as concrete. Another option is to say that only present events are happening, which is Hawthorne's preferred version of the view. The details of this position need not concern us here. What matters is that the passage view, like presentism, can hold that there is something special about the present moment, but unlike presentism it does not need to deny the existence of past and future entities. Because presentism and the passage view take the present to be special, Hawthorne argues, presentists and defenders of the passage view need not relativize contents to times or stipulate that there are times in the index of evaluation.

According to him, we can simply take propositions to bear truth-values *simpliciter*. This renders temporalism obsolete. However, I think this argument is unsound. I have already argued that the presentist is committed to the existence of temporal propositions. A different argument is required to show that the defender of the passage view is also committed to the existence of temporal propositions and indices of evaluation that include times. Consider the sentence:

(19) It was the case that (there is a time t, and dinosaurs exist at t).

On the passage view, the domain of objects remains constant across time, as no object comes into existence or ceases to exist. An individual might become abstract after having been concrete but it doesn't go out of existence. But when we have a constant domain of individuals, then the Barcan and converse Barcan formulas are true. Hence, (19) entails:

(20) There is an x such that it was the case that x is a time and dinosaurs exist at x.

So, there are two times: the present time and x (a past abstract time). But if there are two times, then it seems that we need to relativize to times, even on the passage view.

5 Conclusion

Two of the main debates about tense and time in philosophy of language concern the eternalism–temporalism dispute and the semantics of the tenses. I have argued here that while these debates are far from settled, there are currently more significant pointers to temporalism than eternalism as an adequate account of propositions. This may impact our choice of semantics of the tenses in the English language. Temporalism seems to require a more traditional tense logic that treats the tenses as circumstance-shifting operators.[2]

Notes

1 If you disagree with Aristotle that, say, love is a union, then you are not in the same conversational context, but you pretend to be by entering a dialogue with the asserter of the claims you find problematic.

2 For helpful comments on a previous version of this paper I am grateful to Alex Miller and Bob Hale.

Relativism

PATRICK SHIRREFF AND BRIAN WEATHERSON

Relativism, in the sense we're interested in here, is the view that the truth of a sentence is relative both to a context of utterance and to a context of assessment. That the truth of a sentence is relative to a context of utterance is uncontroversial in contemporary semantics. If the authors of this chapter were to both utter the sentence "I'm Canadian," then one of us would say something true, and the other something false. And that's because the truth of the utterance "I'm Canadian" is sensitive to a feature of the context of utterance, namely the identity of the speaker. And that in turn is explained by the fact that the proposition expressed by that sentence is different in different contexts. Relativists deny that this simple story can explain all the ways in which context affects language.

A core motivation for relativism comes from looking at the problems with other views. So let's start by thinking about what might be happening when a speaker says, "This is tasty." (Call this utterance, which we'll come back to a bit, U, and its speaker S.) The demonstrative 'this' is context-sensitive, but let's assume it is clear what is being referred to, and think about what contribution the predicate is making. There are two natural proposals that are simple, easy to fit into familiar frameworks, and most likely wrong.

First, the predicate might pick out an objective property of tastiness, and when S utters U, she ascribes this property to a thing. This objective view has a number of problems. First, there is a metaphysical problem: Just what is this objective tastiness? Second, there is an epistemological problem. Typically, a speaker like S could be prepared to utter U after taking one bite of the thing. But for most plausible answers to the first question, it is unclear how they could know that the object had that property. The two problems reinforce each other; the more plausible answers to the metaphysical question make the property sensitive to very abtruse conditions, such as how idealized observers would react to ingesting the substance. But that makes it even more unlikely that typical utterances of U satisfy the epistemological requirement. (The points we're making here are well known, but our presentation owes a lot to Lasersohn, 2005.)

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

Second, the predicate might be context-sensitive. For concreteness, let's focus on a very simple contextualist theory of 'tasty.' An utterance of U is true, relative to a context *c*, iff the speaker in *c* likes the taste of the referent of 'this' in *c*. So "This is tasty" and "I like the taste of this" express something very close to the same proposition. (At least they express propositions that are necessarily materially equivalent, but the relation between the two is probably closer than that.) Again there are two problems, both of them to do with the different dynamics of "This is tasty" and "I like the taste of this." A hearer H, who does not like the taste of this substance, could more readily disagree with "This is tasty" than with "I like the taste of this." If H doesn't like its taste, he'll nevertheless concede that S's utterance of "I like the taste of this" is true, but won't concede that "This is tasty" is true. And a similar phenomenon occurs when S herself changes her mind. If later she dislikes the taste of the substance, she will be disposed to retract her utterance of "This is tasty," but not of "I like the taste of this." So both disagreement and retraction data pose problems for the contextualist. (On disagreement, see especially Tamina Stephenson, 2007. On retraction, and most everything else we'll talk about in this paper, see John MacFarlane, 2014.)

If the objectivist and contextualist solutions fail, the relativist suggests that they have a useful alternative. Say that truth is doubly relativized, both to contexts of utterance and to contexts of assessment. So the utterance U, or perhaps just the proposition expressed by it, is true relative to a context of assessment c_a and context of utterance c_u iff the agent at c_a likes the taste of the denotation of 'this' in c_u. So now the truth of the utterance is relative both to the context of utterance and to the context of assessment. This solves the metaphysical problem; talk about what a person likes is unproblematic. It solves at least a version of the epistemological problem; a speaker knows what they like, so can make utterances that are true in their context. It solves a version of the disagreement problem; if H doesn't like the taste of the stuff, he can truly say that what S uttered is not true, since it isn't true in his context. And it explains the retraction data, since once S changes her taste, what she uttered is no longer true relative to her new context, and hence should be retracted.

As everywhere else in philosophy, arguments and claims can be and are contested. In the quick case for relativism we've described so far, there are at least four points where one could readily disagree.

1. Whether objectivism is really vulnerable to the combination of the metaphysical and the epistemological arguments.
2. Whether this version of contextualism is vulnerable to the disagreement and retraction arguments, and if so, whether these problems can be avoided by a more sophisticated contextualist theory.
3. Whether relativism really does avoid the four problems posed for the other theories.
4. Whether there are other theories that also avoid the problems, without running into the problems facing relativism or problems of their own.

In this chapter, we'll focus on the last three points, since they are more widely discussed in the literature than the first one. And indeed, the last three points have been extremely actively debated in recent years. We won't try to take sides in those debates, though we will note that at no point is the final picture nearly as rosy for the relativist as this initial sketch may suggest.

We've so far focused on one particular predicate, 'tasty,' though the points we've been making generalize to most predicates of personal taste. But this is far from the only area

where relativist theories have been proposed. There has been a lot of discussion of relativist theories of epistemic modals. The arguments here are fairly similar to the arguments about predicates of personal taste (though see the discussion below about syntax and control). And MacFarlane has argued for relativist treatments of future contingents, and knowledge ascriptions. We will not spend much time on those constructions explicitly, but the issues they raise are broadly similar to the issues raised by predicates of personal taste, and by epistemic modals.

We will largely bypass two quite different areas where relativist theories have been proposed. Mark Richard (2008) has argued for a relativist treatment of comparative adjectives. And Brian Weatherson (2011) argued for relativist treatments of certain areas of discourse where common assumptions about the area are false and a relativist treatment might be the most charitable fix. As interesting as we find these proposals, they haven't occasioned nearly as much discussion as the proposals discussed above, and so we'll set them aside.

What we will do is first clarify some of the many ways in which the term 'relativism' has been used in recent debates, then review some technical material about indices and contexts that is essential for understanding some relativist views, then look at the main line of recent debate concerning relativism, the one centered on issues about retraction and disagreement, and finally look at some syntactic evidence for relativism.

1 Varieties of Relativism

As we noted in the very first paragraph, it is uncontroversial that sentence truth is sensitive to the context of utterance. It is extremely contentious just how many such sentences are sensitive to the context of utterance. (See, for instance, DeRose, 2009; Harman and Thomson, 1996; Cappelen and Lepore, 2005, for some of the disputes.) But that there is some sensitivity here is uncontroversial. The view that a sentence-type's truth is sensitive to its context of utterance is sometimes called "indexical relativism" (Kölbel, 2004; Einheuser, 2008). For some purposes this is a useful name. In particular, the view that the content of moral predicates, and hence the truth-value of ascriptions of moral predicates, is sensitive to the context of utterance does seem like a form of moral relativism, as that term is standardly understood. It is, for instance, the view that Harman (1975) defends in a self-proclaimed defense of moral relativism. (That this was traditionally known as relativism is stressed in Cappelen and Huvenes, 2014, who draw some interesting conclusions from this fact.) But for present purposes we want to clearly exclude those views, and focus on much more radical proposals that have been recently made.

There are two (overlapping) families of views that have been called relativist, and which we will be concentrating on for the bulk of this chapter. They are:

- Relativism about propositional truth – Whether a proposition is true is not an absolute fact. Propositions can be true relative to some contexts of assessment, and false relative to others.
- Relativism about utterance truth – Whether an utterance is true is not an absolute fact. Utterances can be true relative to some contexts of assessment, and false relative to others.

It isn't always clear whether a particular author, in defending relativism, is primarily defending the first or second of these claims. But it is natural to interpret most relativists as defending relativism about propositional truth. This is most clearly true for Kölbel (2002) and Egan (2007), but there are few relativists that it is hard to interpret as taking this to be the primary focus. The one big exception, however, is the most prominent defender of relativism in the contemporary literature, John MacFarlane (2014). He takes relativism about utterance truth to be the only genuine form of relativism, though he also endorses relativism about propositional truth. We will stay neutral when it comes to the dispute over what is *really* a relativist view and instead we'll just describe a pair of views that are relativist in one of these senses but not the other, to explain how the two senses come apart.

First, let's think about how to make propositional truth, but not utterance truth, relative. Assume that Suzy actually swims, but that she might not have. Then, on a natural way of thinking about modality, the proposition *Suzy swims* will be true relative to the actual world, but false relative to any possible world in which she does not. So propositional truth is relative, with the relativity being to possible worlds.

Cappelen and Hawthorne (2009) argue that the reasoning of the previous paragraph misunderstands the nature of truth and modality. The proposition *Suzy swims* is, they say, simply true. It might have been false. But that doesn't mean it is merely true relative to some world or other; it just means that it might have had a different property than it actually has. Schaffer (2012) argues that the things we say and think, that is, propositions, typically have worlds in their content, so what we express by the sentence "Suzy swims" is the proposition *Suzy swims at @*, and that proposition has a non-relative truth-value.

Even if all that is wrong, and the contents of sentences like "Suzy swims" are propositions that are true in some worlds, false in others, there is a reason not to call this 'relativism.' After all, other worlds don't exist, or at least don't exist in the way ours does. So it isn't true that the proposition expressed by "Suzy swims" is true relative to something and false relative to something else; there isn't a something else for it to be false relative to.

Taking the last point on board, a serious relativism about propositional truth should say that there is a proposition p, and two relata a and b such that p is true relative to a, and false relative to b. One way to do that, as seen in for example Kaplan (1989), is to make truth relative to times, and believe that other times exist. (The contrast here is with the eternalist view of propositions defended by Evans, 1985.) But the radical view that has been central to many recent versions of relativism has been to say that truth is relative to world, time, individual triples. So there is a proposition, for example, that is true relative to a triple $\langle w, t, a \rangle$ iff in w, the individual a disapproves of murder at t. Perhaps, on a relativist framework, this just is the proposition that murder is wrong. The picture of propositions here owes something to the discussion of *de se* beliefs in Lewis (1979), since Lewis thought the contents of such beliefs were sets of such triples. But Lewis put this forward as a theory about mental content; the move to extending it to linguistic content is more recent.

On this view, the contents of utterances will be propositions that can be true relative to one individual (in a world, at a time) and false relative to another. But the utterances themselves will naturally be thought to have absolute truth-value. Think back to the view that propositional truth is just relative to worlds. Then an utterance of "Suzy swims" will, intuitively, be true iff Suzy swims in the world in which the utterance is made. When we think about a counterfactual utterance of "Suzy swims" in a world where she does not, we don't think the utterance is true just because its content is actually true. So although this is a form of relativism about propositional truth, it is not yet a form of relativism about

utterance truth. MacFarlane, who takes utterance relativism to be central, calls this view 'non-indexical contextualism,' with the name meant to highlight that it isn't, by his lights, genuinely relativist.

Now turn to relativism about utterance truth. A simple way to implement this is to say that the propositional content of an utterance is relative to an assessor. So consider a very simple, and surely false, view about 'you' in English. It holds that the content of an utterance of 'you,' relative to a context of assessment, is the agent of that context. And it says that the utterance is true at a context of assessment iff the proposition it expresses relative to that context is (absolutely) true. So an utterance of "You swim" will express a different proposition relative to contexts with different agents. And since some of those propositions will be true, and some false, we have a version of relativism about utterance truth. But this view is consistent with the view that propositional truth is absolute, not relative even to worlds.

So the two versions of relativism are dissociable. But it is also possible to hold them simultaneously, as MacFarlane (2014) does. To set up MacFarlane's view, it is helpful to review the framework against which it was developed.

2 Index, Context, and Content

The existence of indexical terms, like 'I,' means that we can't give a theory for truth-conditions of sentences as such. The sentence-type *I am in Ann Arbor now* doesn't have truth-conditions; only occurrences of this sentence do. So a natural move is to build up a theory that assigns to each term a function from contexts to contents, and use that to provide a theory of which contexts a sentence is true in. It turns out that there are reasons to endorse more complications than this. In particular, sentences like (1) show the need for relativizing truth-conditions relative to both a context and an *index*.

(1) It might have been the case that my actual parents never met.

That's true. But think of how we might naturally provide truth-conditions for it. First, we define the context-relative truth-conditions for "My actual parents never met." The context will provide a world for 'actually' (i.e., the actual world), and an agent for 'my' (i.e., the speaker). Then, we say that the modal operator shifts the world of evaluation. Intuitively, *Might p* is true iff *p* is true in some possible world. So we need some way to see if the content of "My actual parents never met" is true in some other world. But that's hard to do, since (given origin essentialism), there will be no context in which "My actual parents never met" can be truly uttered, so its content will be the function that maps every context into false. And that's the same content as, for example, "Two plus two is five," and so it can't be possibly true.

There are actually two related problems here. One is that while we need to look around the other worlds to see whether some thing is true, the nature of that thing is fixed by the actual context. So if the sentence is uttered by Sasha Obama in this world, the content is something like *It might have been the case that Barack Obama and Michelle Obama never met*. We need to fix the values of the contextually sensitive terms ('my' and 'actual') even when they appear inside operators. The second problem is that something as coarse-grained as a function is very hard to 'shift' in just one respect.

There is a well-known solution to this, developed primarily by Hans Kamp (1971), then put to important philosophical use by David Lewis (1980) and David Kaplan (1989). Say

that our semantic theory will assign a function from both contexts and indices to terms. Ultimately, each sentence will get as its semantic value a function from contexts and indices to truth-values. Lewis describes the distinction between contexts and indices thus,

> A context is a location – time, place, and possible world – where a sentence is said. It has countless features, determined by the character of the location. An index is an n-tuple of features of context, but not necessarily features that go together in any possible context. Thus an index might consist of a speaker, a time before his birth, a world where he never lived at all, and so on. (Lewis, 1980, p. 79)

Indices are structured, and so they can be 'improper,' meaning that it might consist of things that don't go together in the actual world or any possible world. If the index contains just worlds and individuals, the index could be $\langle w, \text{Sasha Obama}\rangle$, even if Sasha doesn't exist in w. Such an index will play a central role in making (1), as uttered by Sasha Obama, true. A context, on the other hand, will by its nature be proper; contexts will go together in the actual world or some possible world. They will pick out a world, and a time in that world, and a person existing at that time in that world, and so on.

Indices are, unlike contexts, 'shiftable.' There can be sentential operators that say the truth-value of the whole sentence is given by looking at the truth-value of the embedded sentence at some different index. Assume, for example, that there is a world parameter in the index, so the index is $\langle w, x\rangle$, where x contains everything else in the index. Then *Might* p will be true relative to context c and index $\langle w, x\rangle$ just in case for some w', p is true relative to context c and index $\langle w', x\rangle$. Note that in this definition, we do *not* shift c; so if c determines that the referent of 'I' is Sasha Obama, that stays even if we 'shift' the index to a world where Sasha does not exist.

The separation between context and index was developed to solve some technical problems, but it can do some philosophical work. The theory associates each sentence with a function from contexts and indices to truth-values. Equivalently, it associates sentence-context pairs with functions from indices to truth-values. So it is natural to say that the content of an utterance is (or is at least intimately connected to) the function associated with the pair consisting of the sentence uttered and the context it was uttered in. If the index is simply a world, then the contents will be functions from worlds to truth-values, as defended by classical contextualists such as Robert Stalnaker (1984). David Lewis (1980) objected that assigning contents at just this stage was arbitrary; why not associate contents with functions from context to truth-values instead? François Recanati (2007) responds well to Lewis's arguments, although his defense requires making indices much more complex. In particular, he includes parameters for times and individuals in the index, leading him to support relativism about propositional truth.

With this background, we can more easily describe two distinctive features of MacFarlane's views. First, he makes indices very complicated indeed. The index might include, among other things, an information set (for interpreting epistemic and deontic modals), a standard of taste (for interpreting predicates of personal taste), relevant alternatives (for interpreting knowledge ascriptions), a time (for handling future contingents), and perhaps many more things. For simplicity, we'll call these things collectively a *perspective*, and say that indices are world-perspective pairs. (Though note that our terminology here requires perspectives to be structured entities, and for them to be potentially improper.) If

the propositional content of an utterance is (intimately connected to) a function from indices to truth-values, then the one proposition will be true relative to one perspective and false relative to another.

So far we only have relativism about propositional truth, or what MacFarlane calls non-indexical contextualism. MacFarlane argues for a second revision to contextualist orthodoxy. Assume that we have a particular utterance U of a sentence S in context of utterance c_u, and that utterance is being assessed in context c_a. And assume that $w(c)$ is the world of context c, and $p(c)$ is the perspective of context c. Sentence S is associated with a function f_S from context-index pairs, that is, context-world-perspective triples, to truth-values. The relativist about propositional truth, but not utterance truth, says that U is true iff $f_S(c_u, w(c_u), p(c_u)) = TRUE$. MacFarlane's relativist[1] says that U is true iff $f_S(c_u, w(c_u), p(c_a)) = TRUE$.[2] Crucially, we assess the utterance itself, and not just its content, by the perspective of the assessor and not from the perspective from which it was uttered. MacFarlane argues that this move allows a better understanding of disagreement and retraction, which were central to the phenomena that motivated relativism. So let's turn to how well relativism explains the phenomena it was designed to explain.

3 Retraction and Disagreement

3.1 Retraction

Contextualists have a difficult time explaining why we retract earlier claims involving predicates of personal taste or epistemically modal assertions when our perspective has changed in the intervening time. Consider this example:

> Kim (age 8): Lunchables are delicious.
> Kim (age 27 being reminded of previous assertion): I take it back/I was wrong/what I said was false. Lunchables aren't delicious.

When Kim retracts her earlier assertion, it is natural to use any of the three forms of retraction listed here. It isn't natural to say either of the following things:

- Lunchables were delicious back then, but they aren't delicious any more.
- When I said that back then, I only meant that they were delicious to me back then.

There is a contrast with how clearly context-sensitive terms like 'here' are used. It isn't natural to use any of the three forms of retraction we attribute to Kim below.

> Kim (in a café): It is pleasant here.
> Kim (in an oil refinery, reminded of previous assertion): I take it back/I was wrong/what I said was false. It isn't pleasant here.

On the other hand, it is natural to say things like:

- It was pleasant where we were, but it isn't pleasant where we are now.
- When I said that back then, I only meant it was pleasant where we were.

Predicates of personal taste, like 'delicious,' don't behave like explicitly context-sensitive expressions like 'pleasant here.' We see the same pattern with epistemic modals.

HAKEEM: It might be snowing outside.
FABIAN: No/that's wrong/that's false, it can't be snowing. I just looked out the window and there were clear skies and the sun was out.
HAKEEM: Really? Then I guess I was mistaken.

If *It might be that p* is true iff the speaker's knowledge is compatible with *p*, as it is on a simple contextualist theory, then none of this conversation makes any sense. But, argue relativists, it is perfectly natural. A natural move here is to argue that the problem with simple contextualism isn't the contextualism, but the simplicity. Exploring the moves that can be made here will take us too far afield; MacFarlane (2014) goes through a number of possible alternative contextualist theories and shows how examples like the ones involving Kim, Hakeem, and Fabian can be generated to raise problems for each of them. Instead, let's look at how the relativist handles the cases.

According to MacFarlane, relativists are committed to the following principle about retraction:

> The speaker ought to retract the assertion if she has good grounds for thinking that its content is false (as assessed from the perspective she currently occupies).

Given that Kim and Hakeem are evaluating their earlier utterances from new perspectives, perspectives where the assertions are now judged to be false, they both should retract their earlier assertions because they now take them to be false. But arguably this principle overgenerates. Consider this example from von Fintel and Gillies (2008).

ALEX: The keys might be in the drawer.
BILLY: (Looks in the drawer, agitated) They're not. Why did you say that?
ALEX: Look, I didn't say that they were in the drawer. I said they might be there – and they might have been. Sheesh. (von Fintel and Gillies, 2008, p. 81)

The lesson they draw from the example is that retraction is somewhat voluntary. Despite what relativists claim, it is not always true that 'might' claims are retracted or rejected in light of new evidence. Instead, what seems to be true is that solipsistic readings for the modals are virtually always available. They say that the relativist can't easily explain this data. MacFarlane (2014, ch. 10) responds by saying, in effect, that epistemic modal claims sometimes mean what contextualists say they mean, and this is compatible with relativism.

3.2 Disagreement and Agreement

The data about retraction are closely related to a phenomenon that classically was central to debates about relativism. A traditional argument for relativism is that it is necessary to explain 'faultless disagreement.' If one person says Vegemite is tasty, and another says that it is not, the alleged datum is that they are disagreeing, but neither is wrong. Objective treatments of taste save the phenomenon of disagreement, but lose the faultlessness. Contextualist,

or otherwise subjective treatments of taste, save the faultlessness but lose the disagreement. Relativism was alleged to keep both. Faultless disagreement plays a big role in Kölbel (2002), but it has dropped out of the recent literature somewhat. But the focus on disagreement remains, with the central claim being that contextualists cannot explain why some conversations are genuinely disagreements. The following is how MacFarlane puts the point using an example from predicates of personal taste:

> If the truth of my claim that a food is "tasty" depends on how it strikes me, while the truth of your claim that the same food is "not tasty" depends on how it strikes you, then our claims are compatible, and we do not disagree in making them. But it seems that we do disagree – even if we are aware that the source of our disagreement is our differing tastes. (MacFarlane, 2014, p. 8)

This is no argument against any kind of objectivist treatment of predicates of personal taste. The issue is solely whether relativism or contextualism does a better job of explaining the facts about disagreement. We'll look at a couple of reasons for thinking that the problem is less pressing for contextualists than it might first seem, then at an interesting attempt to resolve the problems that remain for contextualism, then at some reasons for doubting that relativism helps solve the remaining problems.

3.3 Clarifying the Data

The puzzle for contextualism is supposed to be that there is a big difference between the felicity of Mark's reply in the following two cases.

SALLY: This chili is tasty.
MARK: I disagree. It's too hot.
SALLY: I'm from Barcelona.
MARK: I disagree. I'm from Oslo.

Assume Sally and Mark are both being sincere. So Sally does like the chili and is from Barcelona, and Mark doesn't like it and is from Oslo. In neither case can Mark sincerely repeat the words that Sally uttered. Indeed, he can sincerely utter the negations of the sentences Sally uttered. But in the first case, this seems to amount to a disagreement, and in the second case it does not. If the context sensitivity of 'tasty' and 'I' is explained the same way, this is mysterious.

But note that there are other examples that do not seem to be amenable to a relativist treatment where Mark can express disagreement with Sally.

SALLY: I like this chili.
MARK: I disagree. It is too hot.

What seems to be going on there is that Mark is disagreeing with an attitude that Sally has, but not with any proposition she expressed. After all, Mark presumably agrees with the proposition that Sally likes the chili. That's why he knows he is disagreeing with her. And that's the content of what he uttered. So some disagreements that are triggered by assertions are not with the content of what is asserted. This might be the germ of an idea for how contextualists can explain the data about disagreement, one nicely developed by Torfinn

T. Huvenes (2012). He argues that in a lot of cases of disagreements involving taste, what we see is not a disagreement about any content, but a disagreement of attitudes.

> Two parties disagree just in case there is something towards which they have conflicting attitudes. This sometimes means that there is a content that one party accepts and the other rejects, but that does not always have to be the case. Just as two parties may have conflicting beliefs, they may also have conflicting desires or preferences. (Huvenes, 2012, p. 178)

If Huvenes is right, then we can't draw any conclusions for semantics from the facts about disagreement.

There is a further problem with using facts about disagreement to argue against contextualism. Consider the following dialogue.

SALLY: Joe might be in Boston.
MARK: I disagree he's definitely in China.

If *Joe might be in Boston* just means *For all I know, Joe is in Boston*, then it is *prima facie* unclear why Mark is disagreeing. After all, it is consistent with Joe's being in China that, for all Sally knows, Joe is in Boston. But, say some contextualists, Mark need not disagree with the whole content of Sally's utterance. He may just be disagreeing with the *prejacent* of the modal, that is, that Joe is in Boston.

Most of the terms of disagreement that have been used in examples motivating anti-contextualism can be seen to target something other than the entire proposition (von Fintel and Gillies, 2008, p. 83). This is a particular problem for arguments for relativism involving epistemic modals. It's possible to say "I disagree," "that's false," "no," or "you're mistaken" and disagree with the prejacent of someone's modal claim, not necessarily the whole claim.

One potential avenue for the relativist to get around this worry is to limit the range of disagreement markers that count as expressing the right kind of disagreement. For example, Tamina Stephenson (2007) limits the terms of disagreement in the examples she uses to "no" and "nuh-uh." And John MacFarlane (2014, p. 11) discusses disagreements that more explicitly target the entire asserted proposition such as "the proposition you expressed is false" and "what you asserted is false." The issue with the two former disagreement markers is that they can explicitly target the embedded clause of an expression. Indeed, Stephenson herself provides a clear example of this phenomenon.

MARY: How's the cake?
SAM: I think it's tasty.
SUE: Nuh-uh, it isn't tasty at all! (Stephenson, 2007, p. 512)

The issue with the disagreement markers that MacFarlane uses is that they have become too technical to do the type of work they need to do. Relativism is meant to be an empirical thesis that relies on natural language data to back it up. We have moved well outside of the realm of natural language and the types of natural language intuitions about the acceptability of sentences that we can get when we move to "the proposition you expressed is false" and "what you asserted is false."

Note that the two contextualist responses we've described here are rather complementary. The point Huvenes makes, that disagreements can involve attitudes other than belief,

seems best served to defuse arguments from disagreements concerning predicates of personal taste. And the point that von Fintel and Gillies make, that disagreements can target prejacents, seems best served to defuse arguments from disagreements concerning epistemic modals. It is possible there are replies to this last point; Weatherson and Egan (2011) for example suggest that examples involving agreements are invulnerable to the response that von Fintel and Gillies make. But as it stands, the dominant trend in the literature seems to be in the direction of thinking the contextualist has the resources to answer these relativist arguments.

3.4 Presuppositions and Common Context

There is a more radical, and perhaps more concessive, response to the disagreement arguments available to the contextualist. Dan López de Sa (2008) develops a contextualist theory that explains the disagreement data by positing that for many context-sensitive terms, there is a presupposition that users of the term are in the same context. (Note that López de Sa calls his theory an "indexical relativist" theory, but it is a kind of contextualist theory in the way the terms are being used here.)

It isn't true in general that there is a presupposition of commonality of context. If two speakers both say "I am happy," they should be interpreted as putting forward different propositions. And that is because, in the relevant sense, they are in different contexts. But, perhaps, many terms are not like this. In particular, in cases where there appears to be a problem with explaining the phenomena involving disagreement, perhaps this is not so. So consider the stock example López de Sa uses, a variant on one that may seem familiar by now.

HANNAH: Homer Simpson is funny.
SARAH: I disagree. Homer is not funny.

If 'funny' denotes a different property when Hannah and Sarah use it, there is no disagreement about propositional content here. And the contextualist account of predicates of personal taste would predict that it could, and perhaps often will, denote a different property on different occasions of usage. But it seems that there is a disagreement here, and arguably even one about propositional content. The solution López de Sa offers is that in any conversation, there is a presupposition that we are applying the same aesthetic standards. The model he uses is a suggestion made by David Lewis (1989) in defending a contextualist treatment of claims about value.

> Wouldn't you hear them saying 'value for me and my mates' or value for the likes of you'? Wouldn't you think they'd stop arguing after one speaker says X is a value and the other says it isn't? – Not necessarily. They might always presuppose, with more or less confidence (well-founded or otherwise), that whatever relativity there is won't matter in this conversation. (Lewis, 1989, p. 84)

Here is how López de Sa develops the point.

> According to the approach, 'is funny' triggers a presupposition of commonality to the effect that both Hannah and Sarah are similar with respect to humor. Thus, in any non-defective conversation where Hannah uttered 'Homer is funny' and Sarah replied 'No, it is not,' it would indeed be common ground that Hannah and Sarah are relevantly alike, and thus that they are

> contradicting each other. After all, provided they are alike, either both Hannah and Sarah are amused by Homer or they are not. (López de Sa, 2008, p. 305)[3]

This is an ingenious idea, but there are a few hurdles to be cleared before it could be declared a full solution to the problem. First, it needs a way to deal with eavesdroppers. If Hannah writes "Homer Simpson is funny" on a scrap of paper, and later Sarah chances upon that paper, she can still say that she disagrees. But it is very odd to think there is a presupposition of commonality of taste with anyone who chances upon one's writings. Second, it needs to account for cases where the presupposition is expressly canceled. The Hannah/Sarah conversation feels natural even in cases where it has been made explicit that Hannah and Sarah have completely different tastes, and they are displaying their differences for the amusement of their friends (MacFarlane, 2014, pp. 131–132). Third, it doesn't quite capture the idea that Hannah and Sarah are contradicting each other. When Sarah disagrees, it shows either that there is a proposition one accepts and the other rejects, or that the context is defective. If we thought the data was that there was a contradiction between what they say, López de Sa's approach can't explain that. This is because López de Sa's approach leaves open the possibility that we have just found ourselves in a defective context. And finally, it isn't obvious how to extend this theory to other terms for which relativism seems promising. It is one thing to say that conversations about humor presuppose a common standard for humor. It is much less plausible to say that conversations about what might be the case presuppose that the parties to the conversation know the same things. None of these hurdles seem impossible to clear, but they do raise doubts about whether presuppositions can solve all the contextualists' problems with disagreement.

3.5 Relativism and Disagreement

If, after all that, we conclude that the contextualist still has a problem with disagreement, it's fair to ask whether the relativist does any better. Let's think again about López de Sa's example of Hannah and Sarah.

HANNAH: Homer Simpson is funny.
SARAH: I disagree. Homer is not funny.

A simple relativist theory assigns truth-conditions to Hannah's utterance relative to a context of utterance, her own, and an index that consists of a world-perspective pair. (Remember that we're using 'perspective' to cover everything other than a world that a relativist may want to put into an index, and that it will be a structured entity.) The content of Hannah's utterance will be set by her context. So it will be (or at least will determine) a function from indices, that is, world-perspective pairs, to truth-values. Call the world Hannah and Sarah occupy w, and their perspectives p_H and p_S. Then the proposition that Homer Simpson is funny will be true relative to $\langle w, p_H \rangle$ and false relative to $\langle w, p_S \rangle$. So there is a proposition Hannah accepts and Sarah rejects, and so they disagree. Doesn't this mean that the relativist can explain the sense in which Hannah and Sarah disagree?

Not so fast. Consider another case involving One, who lives in w_1 where Mars has one moon, and Two, who lives in w_2 where Mars has two moons. They make the following utterances:

ONE: Mars has one moon.
TWO: Mars has two moons.

Now most theorists would say that One and Two have expressed propositions that cannot be true together. (As noted earlier, Schaffer, 2012, disagrees, though not in a way that helps relativism.) But they don't disagree. Among other things, they both think that the other speaks truly.

Hannah doesn't just think that the proposition that Homer Simpson is funny is true relative to $\langle w, p_H \rangle$; she thinks it is simply true. That is because she occupies (for want of a better word) the index $\langle w, p_H \rangle$. And One doesn't just think that the proposition that Mars has one moon is true relative to $\langle w_1, p_1 \rangle$, she thinks it is simply true. But in doing so, she need not be in disagreement with someone who occupies a different index, such as Two, and who thinks it is false. It isn't easy to read off the existence of disagreement from the endorsement of conflicting propositions when the parties occupy different indices. And that raises doubts about whether the relativist has really explained the disagreement. (The Mars example is from MacFarlane, 2014, p. 128. Both Dreier, 2009, and Francén, 2010, raise doubts about whether the relativist can explain disagreement.)

Part of MacFarlane's response to this is to insist that the different elements of an index are treated differently. It is just a fact about disagreement that two speakers who assert incompatible propositions in distinct worlds are not disagreeing, while two speakers who assert incompatible propositions from different perspectives in the same world are disagreeing. And that's related to his view of utterance truth. An utterance is accurate if the proposition expressed by the utterance is true relative to the world it was uttered in, and the perspective it is assessed from. So in Two's context, One's utterance is accurate, even though the proposition One expresses is false in Two's context. On the other hand, in Sarah's context, Hannah's utterance is not accurate. So there is at least a sense in which Hannah and Sarah disagree, although One and Two do not. There is still a lot more work to do to turn this into a full theory of disagreement, and chapter 6 of MacFarlane's book has a very careful study of the varieties of disagreement that are possible on a relativist theory, and how they can be used to explain the data. We're not going to attempt to evaluate the success of these responses, but rather conclude by noting that even if the contextualist has work to do to explain the phenomena involving disagreement, so does the relativist.

3.6 Problems with the Data

Most of the arguments in the literature have started with intuitions about disagreement. We don't think there is anything wrong with this in principle; indeed, it is what we've done so far. But when the intuitions get a little shaky, as they are in a few cases we've described so far, it is worth checking them more carefully, against a broader range of informants. And when that is done, it isn't clear that the data help the relativists as much as the relativists have claimed. Knobe and Yalcin (2014) provide evidence that the following claim, which we'll call (J), isn't as empirically justified as the relativists have made it out to be.

> (J) Competent speaker/hearers tend to judge a present-tense bare epistemic possibility claim (BEP) true only if the prejacent is compatible with their information (whether or not they are the producer of that utterance); otherwise the BEP is judged false.

They argue that many relativists, in particular Egan and MacFarlane, are committed to this claim. Although Egan and MacFarlane differ on several points (Egan takes relativism about propositional truth to be primary, MacFarlane relativism about utterance truth), it does seem true that (J) is important to both of them. As Knobe and Yalcin put it,

> Egan and MacFarlane are both clearly animated by the thought that "people tend to assess epistemic modal claims for truth in light of what they (the assessors) know, even if they realize that they know more than the speaker (or relevant group) did at the time of utterance" (MacFarlane 2011: 160; see also Egan 2007: 2–5, the section entitled "Motivation for relativism: eavesdroppers"). (Knobe and Yalcin, 2014, pp. 3–4)

This isn't what their data showed. The subjects were shown speakers whose evidence strongly, but falsely, suggested that Fat Tony was dead. They overwhelmingly said that an utterance of "Fat Tony is dead" is false, but most said an utterance of "Fat Tony might be dead" was true. (Though it is worth noting that the responses displayed a considerable ambivalence; the answers weren't in line with what either a contextualist or a relativist would straightforwardly predict.) The subjects did say that it would be correct for the speaker who said "Fat Tony might be dead" to retract that utterance once it was clear Fat Tony was alive. But this typically wasn't because they thought the earlier utterance was false.

The point of this study was not to directly target intuitions about disagreement, but rather inter-contextual judgments and felicity of retraction. But the issues are closely related. If subjects who know Fat Tony is alive don't judge that an utterance of "Fat Tony might be dead" is false, then either they don't disagree with such an utterer, or the disagreement is, as Huvenes suggests, not the kind that motivates altering our semantics in the direction relativists suggest.

As Knobe and Yalcin are careful to note, even if relativists were completely wrong about inter-contextual evaluation of utterances, about disagreement, and about retraction, there are still other arguments for relativism. We'll end with one other such argument, due primarily to Tamina Stephenson (2007).

4 Control and Syntax

There is a striking semantic/syntactic phenomenon that epistemic modals and predicates of personal taste share. It's easiest to describe the phenomenon if we assume a contextualist semantics, though we'll eventually use the puzzle to cast doubt on that semantics. So assume, for now, that *It must be that p* is true iff *p* is guaranteed to be true by the (possibly idealized) knowledge of *X*, where *X* is an individual or group supplied by context. (And perhaps the amount of idealization is context-sensitive too.) And assume that *F is tasty* is true iff *F* tastes good to (the possibly idealized version of) *X*, where *X* is again supplied by context.

When 'must' or 'tasty' are not embedded, then *X* seems like it has to include the speaker, and perhaps not much more than that. Even making some other taster or knower salient does not suffice to change the value of *X*. For instance, if one utters "Joe is a great cook and connoisseur of fine food. The meals he prepares are always tasty," the second sentence is not naturally construed as saying that *Joe* always likes the taste of what Joe cooks, but that the speaker and her hearer do (or will). Or if, to borrow an example from Weatherson (2011), we say "Jones must know who the killer is," the relevant *X* for interpreting the 'must' consists of the speaker and her hearers, not Jones. There is something strange about this; it normally isn't that hard to make others relevant in a way that makes them the value of a contextually filled variable.

Or, perhaps, it isn't normally that hard with one key exception. Some context-sensitive terms have, as part of their meaning, that their extension includes the speaker. Such terms

include 'I' and 'we.' Perhaps 'must' and 'tasty' are like 'I' and 'we' in this respect. Except, and here is Stephenson's key insight, there is a big difference between 'I'/'we' and 'must'/'tasty.' The former still pick out the speaker (and perhaps those near her) under the scope of an attitude verb. The latter do not. Consider the natural interpretations of these sentences.

- Joe thinks my gumbo is tasty.
- Joe thinks we must have stolen the candy.

In each case, the personal pronouns ('my,' 'we') have their customary denotations. It is the speaker's gumbo that is being praised, and the speaker and her friends who are being suspected of theft. But 'tasty' and 'must' do not behave like that. It isn't that Joe thinks the speaker likes the taste of her gumbo, but that Joe himself does. And it isn't that Joe thinks the speaker's evidence entails guilt, but that Joe's evidence does.

Stephenson points out that we get even more dramatic results with more complex sentences. Consider these two sentences.

- Mary thinks that Sam thinks it must be raining.
- Mary thinks that Sam must think it is raining. (Stephenson, 2007, p. 490)

The value of *X* for the first 'must' has to be Sam, and for the second 'must' it has to be Mary. In neither case is it the speaker, and in neither case is it even particularly optional how to interpret the 'must.' Compare *Mary thinks that Jane likes her house*, which is naturally read as three-way ambiguous. (The house might be Jane's, or Mary's, or a contextually supplied third party's.) The general point here is that the *X* values that the contextualist posits behave rather unlike other implicit or explicit context-sensitive terms.

The relativist explanation of this is that epistemic modals and predicates of personal taste are, to use Stephenson's phrase, "inherently judge-dependent." That is, they are inherently dependent on some perspective for their truth. In the terms we've been using so far, we need a perspective in the index, and not just in the context, to explain the truth of these claims. When this is combined with a natural view that attitude predicates obligatorily shift the perspective (or judge) parameter, then it just naturally falls out that epistemic modals must take on the perspective of the immediate subjective of the attitude verb. Such a semantics is defended by Stephenson, and by Peter Lasersohn (2005).

It falls out of this semantics that there cannot be "exocentric" uses of bare epistemic modals. These are uses of bare epistemic modals that take on the perspective of someone other than the speaker. (A similar point applies to predicates of personal taste.) This is a nice explanation of the fact that it is very hard to generate these exocentric uses. But it arguably overgenerates; there are cases where it seems we do get the exocentric reading. Here is one case from Egan, Hawthorne, and Weatherson (2005).

> Ann is planning a surprise party for Bill. Unfortunately, Chris has discovered the surprise and told Bill all about it. Now Bill and Chris are having fun watching Ann try to set up the party without being discovered. Currently Ann is walking past Chris's apartment carrying a large supply of party hats. She sees a bus on which Bill frequently rides home, so she jumps into some nearby bushes to avoid being spotted. Bill, watching from Chris's window, is quite amused, but Chris is puzzled and asks Bill why Ann is hiding in the bushes. Bill says, "I might be on that bus." (Egan, Hawthorne, and Weatherson, 2005, p. 140)

The natural reading of what Bill says is that for all *Ann* knows, Bill is on the bus. And this is predicted to be impossible on the type of relativist view that gets us the correct results in the obligatory control cases. Stephenson suggests that there is an ellipsis in Bill's sentence. It should really be understood as:

- Ann is hiding in the bushes because I might be on that bus.

So in a sense, it isn't a bare epistemic modal; it is in a 'because'-clause. Moreover, suggests Stephenson, we should take 'because'-clauses to express something like a person's conscious reasoning or rationale. This means that 'because' acts like an attitude verb and shifts the perspective (or judge) of the epistemic modal. (A similar move, in response to a similar objection, is defended by John MacFarlane, 2014, pp. 272 ff.)

The relativist needs two premises here for the defense to work. The first is that all these exocentric uses either are in the scope of an attitude verb, or are in an explanatory context. The second is that it is fair to treat 'because' as sufficiently like an attitude verb for these purposes. A contextualist could well object to either assumption. But even if they grant both assumptions, a contextualist may want to simply resist the whole line of reasoning. At most what these arguments about control show is that 'might,' and 'tasty,' behave rather differently to other context-sensitive terms. There is nothing inconsistent about just accepting that as a surprising fact. And given how radical a thesis relativism seems to many, accepting relativism as an explanation for these facts about control could well be an excessive reaction. The issues here have not been worked out in nearly as much detail as the issues concerning disagreement and retraction, and we are a long way from having a full accounting of the costs and benefits of the possible dialectical moves.

Notes

1 Strictly speaking, to get MacFarlane's exact view of which kinds of views are relativist we need to complicate things even more. MacFarlane explicitly leaves open the possibility that we have a non-indexical contextualist view about some terms, and a relativist view about others, and expressly says that such a view is a form of relativism. So what we should say is that perspectives are subdivided into those features where the context of utterance is relevant for utterance truth, and those where the context of assessment is relevant to utterance truth. If the first set of features is p_u, and the second set is p_a, then the utterance U of sentence S in context c_u will be true, relative to c_a, iff $f_S(c_u, w(c_u), p_u(c_u), p_a(c_a)) = TRUE$. MacFarlane's own view seems to be that p_u will be empty, so the simplified view we've given in the text is a fair representation of how he thinks actual natural languages work. But there are possible languages where the complications noted here are relevant.

2 The differences between these two formulas will become clear throughout §3.

3 López de Sa (2008) follows Stalnaker (2002) in defining a non-defective conversation as a "[conversation] in which the participants' beliefs about the common ground are all correct. Equivalently, a nondefective [conversation] is one in which all of the parties to the conversation presuppose the same things" (Stalnaker, 2002, pp. 716–717). Following López de Sa, the quote has replaced 'context' for 'conversation' in order to avoid confusion with Lewisian 'contexts.'

Modality

BOB HALE

1 Preliminary Considerations: Philosophical Issues

1.1 The Importance of Modal Notions

The notions of necessity and possibility, of what must be so and what may be so, and the derivative notion of contingency – of what is so but might be otherwise – are ones which very few philosophers find themselves able to do without. It is, to take one arguably fundamental case, hard to see how an adequate explanation of the notion of valid argument, as distinct from that of proof in a specified formal system, might run, save in terms of the idea that the conclusion *must* be true if the premises are. Even those vigorously skeptical of modal notions seem unable to voice their skepticism without recourse to them. When Quine denies that there are any statements immune from empirical revision – any necessarily true statements, as he construes the notion – he is not claiming that any statement accepted at any time is one which we *will* at some time in fact reject; what he is denying is the existence of statements which we *could* not be led to reject. It is difficult to see how his skepticism about necessity could be so much as expressed without employing the notion of possibility.[1] And once a notion of possibility has been granted house-room, the intelligibility of a correlative notion of necessity can hardly be denied. It thus appears that philosophical skepticism about necessity must, if it is not to fall into incoherence, take the form of denying the existence of truths having that character, rather than rejecting the notion altogether. That is not, of course, to deny that the notions of necessity and possibility stand in much need of elucidation; on the contrary, it is surely a central task of a philosophy of modality to provide an account of them.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

1.2 *Relative and Absolute Modalities*

As a first step, we may usefully begin by drawing some distinctions among different notions of necessity and possibility. Probably the single most important distinction to be drawn is between *absolute* and *relative* kinds or senses. Roughly speaking, the distinction here is between a truth's being necessary outright or without qualification, and its being a necessary consequence of some pre-assigned collection of statements which are taken to be true, but are not (either necessarily or even typically) themselves true by necessity. When philosophers speak of broadly logical necessity or (what is not to be assumed the same thing) metaphysical necessity, they intend an absolute sense of necessity; but when they speak of natural necessity, physical necessity, biological necessity and the like, it often appears to be relative necessity that they have in mind. What is usually meant by saying that it is, say, physically necessary that p is that it follows from the laws of physics that p; saying that it is physically possible that p is saying that it is consistent with the laws of physics that p. Since the laws of physics – which need not, of course, be as we suppose them to be – are certain true propositions belonging to physics, a proposition cannot be physically necessary without being true; but unless the laws of physics are themselves held to be absolutely necessary, what is physically necessary will not normally be necessarily true in any absolute sense. Similar remarks apply to other relative notions, of course. Clearly, whenever we have a more or less definite body of propositions constituting a discipline D, there can be introduced a relative notion of necessity – expressible by 'It is D-ly necessary that' – according to which a proposition will be D-ly necessary just in case it is true and a consequence of D.[2]

The modal verbs 'must' and 'may' are also commonly employed in epistemic senses, as when we say things like 'He must have got off the train at Oxenholme' (when we know that he was aboard when the train left Penrith and was not on it when it arrived at Lancaster) or 'The train may have been delayed.' Such uses may sometimes be correctly explained as involving relative notions – it being epistemically possible that p if it is consistent with what we know that p, and epistemically necessary that p if it follows from things we know that p.[3] But it seems clear that this is not right for all cases: when we assert that, for all we know, Goldbach's Conjecture may be true, but may equally be false, we are not claiming that neither the Conjecture nor its negation is deducible from number-theoretic propositions which we take ourselves to know, but making the far more modest claim that thus far no one has succeeded either in proving that every even number is the sum of two primes or in finding a counter-example.

The notion of consequence employed in characterizing any relative notion of necessity is plausibly taken to be that of broadly logical consequence.

Since, if there are any statements at all that deserve to be regarded as logically necessary, statements recording the connection between the premises and conclusion of a valid inference are surely among them,[4] our characterization of relative necessity assumes that some truths are broadly logically necessary. It is, however, hard to see how logical necessity itself can be other than an absolute notion. For logical truths to be merely relatively necessary, there would have to be some further truths of which they are (logical) consequences. But first: What could these truths be? Aren't logical truths precisely those which are consequences of the null set of premises? And second: Supposing there is a set K of truths of some other sort, of which logical truths are consequences, what are we to say of the conditionals 'If K then p' where p is any logical truth? How can these conditionals be other than logical truths which are absolutely necessary? It thus appears that, from a

philosophical standpoint, it is the absolute notions that are fundamental. The various relative notions presuppose and are to be explained in terms of them, and it is on them that we shall concentrate here. Accordingly, all subsequent references to necessity and possibility are to absolute notions unless otherwise indicated. In addition, discussion will be largely concentrated upon necessity, although much of what is said will apply, with more or less obvious adjustments, to possibility.

1.3 Comparability and Strength of Absolute Modalities

The foregoing remarks leave it open that there may be more than one absolute notion of necessity. If there is more than one – as would be the case, for example, if logical and metaphysical necessity are distinct notions and both are absolute – this gives rise to questions of comparability and relative strength. In saying that two notions of necessity – necessity$_1$ and necessity$_2$ – are comparable, I mean simply that either 'it is necessary$_1$ that *A*' entails 'it is necessary$_2$ that *A*' whatever statement *A* may be, or conversely. It is clearly a substantial claim that two notions of necessity are comparable. It is more often simply assumed rather than argued that logical necessity is the strongest kind. If attention is restricted to absolute notions and their comparability is assumed, it is hard to see how the common view could seriously be questioned. For if there is an absolute notion of necessity, necessity*, which is distinct from but comparable with logical necessity, either 'It is necessary* that *p*' entails 'It is logically necessary that *p*' or conversely. And likewise for the corresponding notions of possibility: either 'It is possible* that *p*' entails 'It is logically possible that *p*' or conversely. If necessity* is stronger than logical necessity, then possibility* is weaker than logical possibility and so does not entail it. But since it is logically possible that *p* provided that *p* entails no contradiction, this can only be so if it is possible* for a contradiction to be true. The current vogue for 'true contradictions' notwithstanding, it seems to me that there is no good sense of 'possible' for which this holds. If comparability is not assumed, however, the claim that logical necessity is the strongest kind of necessity calls for further argument.

An argument to the purpose was put forward by Ian McFetridge in a posthumously published essay on logical necessity (McFetridge, 1990). As his original argument involves some avoidable complications, I shall give my own version. If there is a kind of absolute necessity than which logical necessity is not stronger, there will likewise be a corresponding kind of possibility than which logical possibility is not weaker; and for this notion of possibility, it will hold that it is possible for the premise(s) of a valid argument to be true but its conclusion false.[5] Let us use '*Poss A*' to express that it is, in this sense, possible that *A*. We make the following five assumptions about entailment and '*Poss*' (I write $A \Rightarrow B$ for '*A* entails *B*,' understood as meaning that there is a valid argument from *A* to *B*):

(A1) If $A \Rightarrow$ B then $A \wedge C \Rightarrow B$ *and* $C \wedge A \Rightarrow B$
(A2) $A \Rightarrow A$
(A3) If $A \Rightarrow B$ and $A \Rightarrow C$ then $A \Rightarrow (B \wedge C)$
(A4) If *Poss A* and $A \Rightarrow B$ then *Poss* B
(A5) $\neg$*Poss* $(A \wedge \neg A)$

On these assumptions, we can show that if $A \Rightarrow B$ then $\neg$*Poss* $(A \wedge \neg B)$:

1	(1) $A \Rightarrow B$	Assumption
2	(2) *Poss* $(A \wedge \neg B)$	Assumption

1	(3) $(A \wedge \neg B) \Rightarrow B$	(1) by (A1)
	(4) $\neg B \Rightarrow \neg B$	by (A2)
	(5) $(A \wedge \neg B) \Rightarrow \neg B$	(4) by (A1)
1	(6) $(A \wedge \neg B) \Rightarrow (B \wedge \neg B)$	(3), (5) by (A3)
1,2	(7) *Poss* $(B \wedge \neg B)$	(2), (6) by (A4)
	(8) $\neg$*Poss* $(B \wedge \neg B)$	by (A5)
1	(9) $\neg$*Poss* $(A \wedge \neg B)$	(2), (7), (8) by *reductio ad absurdum*

Remember that *Poss* represents *any* sense of 'possibly' conforming to (A4) and (A5), so that if our ancillary assumptions about entailment are correct, it follows that there is no such (absolute) sense of 'possibly' in which it is possible that the premise(s) of a valid argument should be true but its conclusion false. I do in fact hold all five assumptions to be met by entailment and any reasonable notion of possibility. Obviously anyone wishing to impose a quite strong relevance-constraint upon entailment will find (A1) unacceptable; and paraconsistent logicians may feel free to reject (A5). It seems, nevertheless, to be a result of some interest and importance that, without assuming comparability, it can be shown from assumptions which, whilst not quite indisputable, are not grossly immodest, that logical necessity is the strongest absolute notion of necessity.[6]

1.4 The Philosophical Problem of Necessity

What should a philosophical account of the (absolute) notion(s) of necessity accomplish? Michael Dummett provided what many ought to find an apt formulation of the task confronting us:

> The philosophical problem of necessity is twofold: what is its source, and how do we recognize it?[7]

As pinpointing what has been the preoccupation of much philosophical discussion of necessity, Dummett's formulation can scarcely be faulted. Plainly, however, Dummett's questions carry presuppositions which both can be, and actually have been, called into question. One is that there is indeed such a thing as necessity – that the notion of necessity has application. Another, which may still be questioned by one who grants the first presupposition, is that the notion has application in such a way as to give rise to a genuine epistemological problem: in effect, that there is a distinctive class of *truths* about what is necessary – truths of the form 'It is necessarily true that *p*' – concerning which it is to be enquired how we (can) know them. These presuppositions will occupy us for the remainder of this chapter.

2 Quine's Skepticism and Reactions to It

2.1 Quine's Solution to the Problem of Necessity

The burden of Quine's celebrated attack upon the 'first dogma' of empiricism is that there are no statements immune to revision in the face of recalcitrant experience, and so no statements which are analytic in the sense of holding true, come what may. Since Quine makes no distinction between the claim that a statement is analytic and the claim that it is necessary – holding, as he does, that the problem of making sense of the adverb 'necessarily' is

one and the same with that of achieving a satisfactory explanation of 'analytic' – his attack on the notion of analyticity is simultaneously one upon that of necessity, and his eventual denial that there are any statements which are true come what may is thus a denial that there are any necessary truths. He may thus be seen as rejecting both presuppositions of Dummett's formulation of the problem of necessity. Equally well, he may be seen as offering a negative solution to it. Earlier and contemporary empiricists, including the logical positivists (cf. Ayer, 1946, ch. 4), had accepted that there are necessary truths, knowable *a priori*, and thus confronted Dummett's problem in spades: how to explain, compatibly with their central thesis that all genuine knowledge derives from sense-experience, first, how there could be such truths and, second, how they could be known. Quine's solution was as dramatic as it was radical: there are no necessary truths, hence no satisfiable demand for an account of their source, nor for an explanation how they are known.

2.2 Quine's Skepticism Finessed?

It may well seem that if Quine is right then necessity is, to borrow some words from Hilary Putnam, yet another example of a subject without an object. And that it surely would be, if Quine were right in thinking that there are no statements that are true come what may; for what are necessary truths, if not that? Interestingly, Putnam himself argues, in the paper from which the words are borrowed,[8] that this conclusion is too swiftly drawn. We can grant that Quine's attack is entirely destructive of a certain 'epistemic' notion of necessity – the conception of a true statement as necessary iff not liable to rational revision – and yet still find application for another philosophically important, but non-epistemic, notion. What he has in mind is what many philosophers, following Kripke (and Putnam himself), have called metaphysical necessity.[9] The presently relevant point of this shift in thinking about necessity, as Putnam seems here to conceive it, is that it detaches the notion of necessity from that of being knowable *a priori* (which Putnam, like Quine, understands as requiring unrevisability). According to this way of thinking, it is metaphysically necessary, for example, that water is H_2O (that is, there is no possible world in which water exists but is not this compound of hydrogen and oxygen);[10] but this necessity is something we know – and can only know – *a posteriori*. And because the claim of necessity does not entrain apriority, it escapes Quine's attack.

Whatever may be said in favor of the notion of metaphysical necessity (or in favor of making space for the conception of necessities knowable only *a posteriori*), there is an obvious difficulty with this way of rescuing the topic of necessity from Quine's clutches. This emerges as soon as we reflect on how, in more detail, *a posteriori* necessities are supposed to be known. At least if we follow Kripke's own suggestion – and no one, to my knowledge, has proposed anything better, or significantly different[11] – our *a posteriori* knowledge that water is necessarily H_2O is the output of a *modus ponens*, applied to two other pieces of knowledge as premises: that water is H_2O, and that if water has a certain chemical composition, it has that chemical composition of necessity (that is, its chemical nature is essential to it). On anyone's view, our knowledge of the minor premise cannot but be *a posteriori*, and this is why our knowledge of the conclusion is so too. But in Kripke's view, the conditional major premise is known by 'philosophical analysis' (Kripke, 1971, p. 153) – and is thus, presumably, a necessary truth, known *a priori*. If that is right, the possibility of *a posteriori* necessities rests squarely on the shoulders of *a priori* necessities; it therefore appears to be a complete illusion that Quine's attack on the latter has been finessed.[12]

2.3 More Direct Defenses against Quine's Challenge

It thus appears that if we are to take necessity seriously, we have no option but to confront Quine's challenge directly. Full discussion of this issue is beyond the scope of this chapter; but two possible lines of counter-attack may be briefly reviewed.[13] First, it may be argued that Quine's own position – an uncompromisingly global empiricism in which all statements we accept have the status of empirical hypotheses, up for revision or retention in the light of experience, with the choice being guided by broadly pragmatic considerations[14] – is itself untenable as a direct consequence of his refusal to accord *a priori* status to any statements whatever. An argument to this general effect – which, so far as I know, has yet to receive an effective counter – has been advanced by Crispin Wright (q.v. Wright, 1986). Wright's central claim is that Quine's position is ultimately unstable because viciously regressive. Among the statements which, in Quine's view, must be up for revision in any (dis)confirmation situation will be certain conditionals purporting to record the logical consequences of our currently accepted combination of empirical theory plus underlying logic. In other words, one option when we are confronted with some recalcitrant sequence of experiences will be to retain our threatened empirical theory along with its underlying logic, eliminating recalcitrance by way of rejecting the claim that their combination does, after all, have the troublesome consequences.[15] When, if ever, should we exercise this particular option? Well, presumably, when doing so results in the optimal balance between minimizing clashes with experience and maximizing simplicity and economy of overall theory. To arrive at a rational assessment on that matter, we must see how that option fares in comparison with the various others available. This will involve, *inter alia*, judgments about what the observational consequences are of the various options. But these in turn will require deploying some hypotheses about the logical consequences attending implementation of the different options. With which hypotheses about their logical consequences should we work? Well, clearly we should work with the *best* such hypotheses. And we should decide what those are by applying Quine's pragmatic criteria; but it was precisely in the course of trying to apply those criteria that we were led to our present question. If we have not come full circle, then we have set off on a vicious infinite regress. If we are ever to be able to apply Quine's pragmatic guidelines, some statements must be kept out of the pragmatic melting pot and treated as not being up for empirical revision. If not, then, as Wright in one place puts it, "the pragmatic methodology is drained of all directive content" (Wright, 1986, p. 222).

Second, and independently of the preceding counter, a defender of necessity might preserve the linkage between it and apriority[16] by severing that (implicit in Quine and explicit in Putnam) between apriority and (absolute) unrevisability. There is no evident reason why we should take ourselves to be immune from error in the *a priori* detection of necessary truths; on the face of it, having *a priori* grounds for believing that *p* is one thing, and being infallible about the matter is another. (See Chapter 23, ANALYTICITY, §I for some further discussion of apriority.)

3 Modal Realism 1: Realism about Possible Worlds

As already remarked, it is a further presupposition of Dummett's formulation of the problem of necessity that necessary truths constitute a distinctive class of truths: that there are, in some sense, genuinely modal facts, not reducible to facts of any other kind. In this sense,

Dummett's formulation presupposes a realistic attitude towards modality. And as also remarked, realism in this sense has not gone unchallenged. Opposition to it goes at least as far back as Hume, who denied that necessity is anything to be detected among the objects of knowledge, maintaining instead that it is nothing but the projection of our own sentiments or attitudes, themselves induced by patterns in our experience (see Hume, 1960, Bk.1, Sec. xiv). Hume, of course, had causal or natural necessity in view. But some, following Hume's lead quite closely, have sought to extend his approach to modality in general (cf. Blackburn, 1984, pp. 210–217; 1986; Craig, 1985). Others have evinced less sympathy with Hume's projectivist explanation, but have endorsed the non-cognitivism about necessity on which it builds.[17] We shall return to this line of anti-realist theorizing. I want first to discuss a different form the realism it opposes may assume which entails, but goes appreciably beyond, the comparatively modest variety just sketched, and which has been the focus of much recent discussion: realism about possible worlds.

3.1 Modal Logic and Possible-World Semantics

Before we proceed with our discussion of this type of realism, a brief outline of the main ideas of modal logic and the so-called possible-world semantics developed for it in the 1950s and 1960s may be useful.

3.1.1 Modal Logics

A language for modal logic is obtained by adding some modal operators – usually, two unary sentential operators, $\Box$ and $\Diamond$, read as 'necessarily' and 'possibly' – to the underlying language for non-modal logic (which is usually first-order, but may be higher-order). A system of modal logic is then obtained by adding axioms, or rules of inference, governing these new operators. Depending upon what axioms or rules are chosen, weaker or stronger modal logics result. The weakest system, known as K, is obtained from the underlying non-modal logic by adding $\Box(A \rightarrow B) \rightarrow (\Box A \rightarrow \Box B)$ as an axiom and a rule of necessitation which allows us to assert $\Box A$ as a theorem whenever A is a theorem. If we understand the necessitated, or strict, conditional as asserting that A entails B, then the axiom says that what is entailed by a necessary truth is itself necessarily true. A stronger, but still quite weak, system, known as T, is obtained by adding the further axiom $\Box A \rightarrow A$, which says that what is necessarily true is true. The operator $\Diamond$ is usually taken to be interdefinable with $\Box$. If $\Box$ is taken as primitive, $\Diamond$ may be defined $\Diamond A = def \neg\Box\neg A$. If $\Diamond$ is primitive, $\Box$ can be defined $\Box A = def \neg\Diamond\neg A$; in this case, the axioms will be adopted in their equivalent forms governing possibility (for example, the T axiom becomes $A \rightarrow \Diamond A$). Stronger systems are obtained by adding further axioms, which may seem less intuitively obvious. Two of the most important are $\Box A \rightarrow \Box\Box A$ and $\Diamond A \rightarrow \Box\Diamond A$.[18]

The first of these, which asserts that what is necessary is necessarily necessary, is the characteristic axiom of the system S4 – the system which results from adding this axiom to those for the system T. The second, which asserts that what is possible is necessarily possible, is the characteristic axiom of the yet stronger system S5 – which results from adding this axiom to those for T. A third is $A \rightarrow \Box\Diamond A$, known as the Brouwersche axiom, which, if added to the axioms for the system T, gives another system, B, which, like S4, is intermediate in strength between T and S5, but disjoint from, and neither stronger nor weaker than, S4.

The characteristic axioms for S4 and S5 involve what are known as *iterated* modalities – that is, unbroken sequences of modal operators such as occur in the formulae $\Box\Box A$ and $\Box\Diamond A$.

Since the converses of these axioms – *viz.* $\Box\Box A \rightarrow \Box A$ and $\Box\Diamond A \rightarrow \Diamond A$ – are already theorems of the weaker system T, the effect of the axioms is to ensure the equivalence of the iterated modalities involved to simple modalities. Thus in S4, any finite sequence of $\Box$s can be simplified to a single $\Box$, and in S5 any sequence $\Box\Diamond$ simplifies to $\Diamond$. Thus adding these axioms reduces the number of inequivalent modalities. Since the S4 axiom is a theorem of S5, both kinds of simplification can be effected in the latter system. For example, $\Box\Box\Diamond A$ simplifies to $\Diamond A$; and since $\Diamond\Diamond A \rightarrow \Diamond A$ and $\Diamond\Box A \rightarrow \Box A$ are theorems of S4 and S5 respectively, $\Diamond\Diamond\Box A$ simplifies in S5 to $\Box A$. Maximum simplicity is achieved in S5. By a *modality* is meant an unbroken sequence of zero or more of the modal operators and negation. In S4, there are just 14 inequivalent modalities, *viz.* _ (the null modality), $\Box$, $\Diamond$, $\Box\Diamond$, $\Diamond\Box$, $\Box\Diamond\Box$, $\Diamond\Box\Diamond$, together with their negations $\neg$, $\neg\Box$, and so on. In S5, these reduce to six, *viz.* _, $\Box$, $\Diamond$, and their negations. In T, by contrast, no simplification is possible, so that there are infinitely many distinct modalities.[19]

If the axioms for a given modal system are added to a system of first- or higher-order quantification theory, we obtain a system of quantified modal logic – quantified K, or quantified S5, say. The interaction of modal operators with quantifiers produces interesting results and gives rise to disputed questions about what principles involving such interactions should hold. Two particularly interesting and controversial such principles are the Barcan Principle $\forall x\Box A \rightarrow \Box\forall x A$ and its converse, $\Box\forall x A \rightarrow \forall x\Box A$. Which, if any, of these principles is a theorem depends on both the underlying non-modal logic and the modal axioms adjoined to it. If the underlying logic is classical, Converse Barcan is provable in quantified K, and so in any stronger system; and Barcan is provable in quantified B, and so in quantified S5, which includes B. Barcan is controversial, at least in part, because it seems, at least to some thinkers, that it could be true that everything which actually exists is necessarily thus-and-so, but also true that there might have existed something which is not thus-and-so. One reason why Converse Barcan is controversial can be seen by considering its instance: $\Box\forall x\exists y\ x = y \rightarrow \forall x\Box\exists y\ x = y$. The antecedent here is itself a theorem of quantified K, since it follows from the Reflexivity of Identity $\forall x\ x = x$ by existential generalization and the Rule of Necessitation. So the consequent is likewise a theorem. But the consequent is naturally understood as asserting that everything exists of necessity, contrary to the widespread belief that there are many things which might not have existed. Neither Barcan nor its Converse are provable, even in quantified S5, if the underlying logic is free (see Glossary).

Questions about which modal principles – the K, T, S4, B, and S5 axioms, for example, and the Barcan and Converse Barcan principles – should be among the theorems of a modal logic have attracted a good deal of discussion. Such questions have little or no point unless asked with respect to some proposed interpretation of the modal operators. If $\Box A$ is interpreted *alethically*, so that it expresses that it is *necessarily true* that *A*, then it is clear that at least the K and T axioms should hold, but there is more scope for argument about the stronger B, S4, and S5 principles. If, instead, $\Box$ is interpreted *deontically*, as expressing that it *ought to be the case* that *A*, or *doxastically*, as expressing, say, that it is *reasonable to believe* that *A*, then it should not conform to the T axiom, even if it should satisfy the K axiom. And of course, other interpretations are possible. Just as 'may' and 'must' are often used to express epistemological claims (e.g., 'She may have missed the train,' 'I must have left my wallet in my other jacket pocket'), so $\Box$ and $\Diamond$ may be interpreted epistemically, to express claims about what may or must be the case, relative to a certain body of knowledge. Further, different alethic interpretations are possible, so that $\Box$ may be taken to express logical necessity, or metaphysical necessity, or natural necessity, to mention only the most obvious alternatives.[20]

3.1.2 *Possible World Semantics*

It comes very easily to us to express modal thoughts in terms of possible worlds – what is necessarily true is what holds true not only in the actual world, but in all other possible worlds as well; what is possibly true is what holds true in some possible world – perhaps the actual world, but perhaps some merely possible world.[21]

These easy paraphrases form the starting point of possible-world semantics for modal logics, first developed in the late 1950s and early 1960s by Saul Kripke and others. Broadly speaking, an interpretation of an otherwise standard first-order language to which modal operators are added consists of a set, or domain, W, of possible worlds (with one of them, w_α designated as the actual world) and a set, or domain, I, of individuals, together with functions which assign subsets I_w of I to the elements of W, elements of I to the individual constants (if any) of the language, and, relative to each element of W, subsets of I_w^n to the n-place predicates of the language. Under more or less obvious stipulations for dealing with connectives, quantifiers, and modal operators, we can then define what is required for a formula of the language to be true at a world w in W. A formula is true in the interpretation if true at w_α and valid if true in all interpretations. In this setting, the condition for $\Box A$ to be true at w_α is that A be true at each w in W, while that for $\Diamond A$ to be true is that A be true at some w in W. Thus $\Box$ and $\Diamond$ are, in effect, interpreted as universal and existential quantifiers over worlds.

A semantical account along these lines *may* be viewed as no more than an algebraic or model-theoretic device, in relation to which metalogical results about the soundness, completeness and so forth of a specified system of modal logic may be established (see Chapter 35, REFERENCE AND NECESSITY, §2). From such a standpoint we are under no stronger pressure to take the informal accompanying patter about possible worlds as aspiring to literal truth than we are so to regard talk of truth-values intermediate between truth and falsehood as it occurs in the many-valued interpretations by means of which, say, independence results are established. If, however, we are disposed to view possible-world semantics as real semantics – that is, as furnishing genuinely illuminating statements of truth-conditions for modal sentences, and perhaps as forming the basis of explanatory accounts of other concepts, then, or so it seems, we must take the possible-world semantics as attempting, in Alvin Plantinga's memorable phrase, "to spell out the sober metaphysical truth about modality" (Plantinga, 1974, p. 125): we must take seriously the idea that modal statements are, in effect, to be construed as quantifications over a domain of real entities comprising possible worlds. No one has defended such a realistic attitude towards possible worlds with greater ingenuity and resourcefulness than David Lewis. A full-scale discussion of his position lies well beyond the scope of the present chapter, which must settle for a brief and selective review of the main arguments advanced on either side, and of some of the alternatives to Lewis's uncompromising realism which have been canvassed.

3.2 *Arguments for Realism about Worlds*

3.2.1 *The Paraphrase Argument*

In an early defense of realism, Lewis gives some prominence to an argument which represents the central thesis of his realism – that there are possible worlds other than the one we happen to inhabit – as no more than an innocent paraphrase of a very general modal belief from which he expects no one to dissent:

> It is uncontroversially true that things might have been otherwise than they are…. Ordinary language permits the paraphrase: there are many ways things could have been besides the way

> they actually are. On the face of it, this sentence is an existential quantification. It says that there are many entities of a certain description, to wit 'ways things could have been.' I believe that things could have been different in countless ways; I believe permissible paraphrases of what I believe; taking the paraphrase at its face value, I therefore believe in the existence of entities that might be called 'ways things could have been.' I prefer to call them 'possible worlds.' (Lewis, 1973, p. 84)

Given Lewis's insistence, equally prominent in this early discussion, and repeated in subsequent defenses, that other possible worlds are (just) more things of the same kind as the actual world, it would seem to follow that the actual world is one of the ways things could have been – the way they are. This strongly suggests what might be called a Tractarian conception[22] of possible worlds, as collections, probably maximal, of possible states of affairs, the actual world being thought of as that collection of possible states of affairs, each of which is realized.

Whatever merit this argument might be thought to possess, it is clear that it can provide absolutely no support for the version of realism which predominates even in Lewis (1973), and on which Lewis stabilizes in subsequent writings (cf. especially Lewis, 1986, ch. 1), according to which worlds are spatio-temporally and (therefore) causally closed systems, typically largely populated by concrete entities of various kinds, the actual world being identified not as a certain collection of states of affairs, but with one particular such system of concrete (and possibly also abstract) entities, comprising – as Lewis charmingly puts it – Lewis and all his surroundings.[23] It is to this rival conception that Lewis appeals (only paragraphs later than the one in which the quoted argument appears), in objecting to the view that (merely) possible worlds are maximally consistent sets of sentences:

> given that the actual world does not differ in kind from the rest, [this view] would lead to the conclusion that our actual world is a set of sentences. Since I cannot believe that I and all my surroundings are a set of sentences … I cannot believe that other worlds are sets of sentences either.[24]

Lewis is chary of saying outright whether worlds themselves are concrete entities, pending clarification of the abstract/concrete distinction; but he is confident that, if the distinction can be satisfactorily elucidated at all, it will not be found that the actual world falls on one side of the divide and other possible worlds on the other.

3.2.2 Arguments from Explanatory Virtue

It is hardly surprising that the Paraphrase Argument disappears from view in Lewis's later defenses of his realism, as does the suggestion that realism involves no serious departure from 'common opinion' (cf. Lewis, 1986, p. 133, also p. 100). Argument of a quite different stripe comes to center stage – argument broadly to the effect that realism about worlds should command our acceptance by dint of its distinctive explanatory advantages. These, in Lewis's view, are many, various, and substantial. Fundamental, of course, must be the claim that by understanding ordinary modal claims as, in effect, quantifications over a domain of possible worlds, we gain an illuminating account of their truth-conditions. Building on this, it may be claimed that a satisfying explanation can be given of uncontroversial facts about validity and invalidity of modal inferences. A simple illustration is afforded by the patently invalid inference from $\Diamond p$ and $\Diamond q$ to $\Diamond(p \wedge q)$. When modal operators are construed as, in effect, quantifiers over a domain of possible worlds, this inference assumes the form: $\exists w$

True(p, w), $\exists w$ *True*(q, w) $\therefore$ $\exists w$ *True*($p \wedge q$, w), the invalidity of which is then readily recognizable as a special case of the generally invalid quantificational pattern: $\exists xA$, $\exists xB \therefore \exists x(A \wedge B)$. Likewise, the validity of $\Box p$, $\Box q \therefore \Box(p \wedge q)$ reappears as a special case of the quantificational validity $\forall xA$, $\forall xB \therefore \forall x(A \wedge B)$. Lewis is at pains to stress what he sees as the advantages of his realism as a source of good explanations of other philosophically important and perhaps otherwise problematic concepts, besides those involved in modal logic, narrowly conceived. A prominent example is the subjunctive or counterfactual conditional 'If it were the case that p, it would be the case that q,' whose truth-condition on Lewis's account is, roughly, that q holds true at all those possible worlds at which p holds which are 'closest' to (i.e., most like) the actual world. Another is the analysis of propositions as sets of possible worlds, under which the proposition that p is identified with the set of possible worlds at which it is true that p. In general terms, the thought is that these and other explanatory advantages cannot be enjoyed without embracing realism about possible worlds themselves.[25]

3.3 Alternatives to and Arguments against Realism about Worlds

There are two fairly obvious ways in which this kind of case for realism may be countered. First, it may be granted that possible-worlds apparatus does indeed bring distinctive explanatory advantages, but argued that these advantages can be enjoyed without engaging in the full-blooded realism about possible worlds which Lewis advocates. Second, it may be argued that the apparent explanatory advantages of possible-world semantics are illusory, because alternative explanations can be provided which make no essential play with possible worlds at all. We shall briefly review some of the main lines of thought which have been advanced under these two broad headings.

Under the first, one early reaction to Lewis's uncompromising or 'extreme' brand of realism was Robert Stalnaker's moderate realism. Stalnaker takes Lewis's realism to consist of four theses: in his own words, they are:

(1) Possible worlds exist
(2) Other possible worlds are things of the same sort as the actual world – "I and all my surroundings"
(3) The indexical analysis of the adjective 'actual' is the correct analysis[26]
(4) Possible worlds cannot be reduced to something more basic (Stalnaker, 2003, p. 27)

It is, Stalnaker claims, thesis (2) which "gives realism about possible worlds its metaphysical bite, since it implies that possible worlds are not shadowy ways things could be, but concrete particulars, or at least entities which are made up of concrete particulars and events" – so that "even a philosopher who had no qualms about abstract objects like numbers, properties, states and kinds might balk at this proliferation of full-blooded universes which seem less real to us only because we have never been there" (Stalnaker, 1976, p. 68). His moderate realism results from rejecting thesis (2), whilst retaining the other three. Rejecting thesis (2) allows us to preserve the identification of the actual world with David Lewis and his surroundings, whilst viewing other possible worlds as no more than ways things might have been, and thus as things of a quite different kind from the actual world. Stalnaker is less than fully explicit on what precisely 'ways things might have been' are, but his view appears to be that they are properties (and so not collections of systems of concrete objects, such as the actual world is).[27] Since properties can be held to exist uninstantiated, this leaves us free

to maintain that (merely) possible worlds exist; "that there really are many ways that things could have been – while denying that there exists anything else that is like the actual world" (Stalnaker, 1976, p. 68).

Whatever ontological advantage may be thought to attach to maintaining that merely possible worlds are entities of a radically different kind from the actual world, it appears to have some awkward consequences, at least for anyone who wishes to regard possible-world semantics as providing an illuminating account of the truth-conditions of modal statements. An immediate difficulty arises over the interpretation of modal operators as quantifiers over possible worlds. Since merely possible worlds are to be thought of as properties, it follows that they cannot, as is usually supposed, be first-order quantifiers over objects, but must be (at least) second-order quantifiers over properties.[28] This might, by itself, be thought to render moderate realism a significantly less attractive option (and would, of course, be seen as a fatal flaw by those who view higher-order quantification with no less suspicion than they do Lewisian worlds). But there is a more straightforward difficulty which is quite independent of any hostility towards higher-order quantification. If world quantifiers range over a homogeneous domain of properties, that domain cannot include the actual world; with the result that the semantics will fail to validate such obviously valid inferences as those from a proposition's necessary truth to its truth *simpliciter* (that is, truth in the actual world), and from its truth to its possible truth. This problem was first noticed, so far as I know, by Colin McGinn,[29] who suggests that Stalnaker's only way out is to distinguish between the actual world (now understood as the way things are) and the world (understood as Lewis and his surroundings). But this, McGinn suggests, is an unwelcome move, precisely because the appeal of moderate realism derives, in large part, from its contrast between merely possible worlds as ways things might have been and the actual world as a comprehensive collection of bits and pieces. This is perhaps a fair point against Stalnaker's actual position, but it is worth noticing that there is space for a somewhat different version of moderate realism which escapes the objection.

The difficulty is an immediate consequence of Stalnaker's rejection of thesis (2). But thesis (2), as he understands it, is really two quite independent theses:

(2*a*) Other possible worlds are things of the same sort as the actual world
(2*b*) The actual world is David Lewis and his surroundings

Both theses are essential to Lewis's full-blooded realism; in consequence, the rejection of either separately defines a more moderate position. Retention of (2*b*) coupled with rejection of (2*a*) – the option Stalnaker actually plumps for – is what leads to the problem just discussed. If, instead, we retain (2*a*) but reject (2*b*), the problem does not arise. On this position, every possible world is a way things might have been, the actual world being just that one among them which is the way things happen to be. Moderate realism of this kind can, in contrast with Lewis's, claim the support (for what that is worth) of his paraphrase argument for possible worlds. If ways things might have been are thought of as determined by maximally consistent sets of propositions, realism of this kind enjoins a broadly Tractarian conception of possible worlds and perhaps coincides with a position defended by some contributors to the debate (cf. Adams, 1974; Hintikka, 1969; Plantinga, 1974, ch. 4).

It is arguably at a considerable advantage over Lewisian realism, since it is clear enough how, on this view, atomic propositions are guaranteed determinate truth-values at each possible world, whereas that is anything but clear, if the actual world consists merely of Lewis

and his surroundings, and other worlds are likewise conceived as comprehensive collections of similar bits and pieces, at least unless proposition-like entities are smuggled in under the somewhat opaque heading of 'surroundings.' The view will, of course, have little appeal for those, such as Lewis and Stalnaker, who think propositions are best analyzed as sets of possible worlds; but it is more than a little questionable whether that can withstand scrutiny.[30] It should, on the other hand, be congenial to those philosophers who, in broadly Fregean tradition, hold ontological questions to be best conceived as questions about truth and logical form. (See Chapter 20, REALISM AND ITS OPPOSITIONS, §1.)

A more recent and, in some respects, more radical suggestion, aimed at securing the presumed advantages of construing modal operators as quantifiers over possible worlds at bargain price, is what Gideon Rosen calls *modal fictionalism*. On this proposal[31] we should prefix possible-world paraphrases of modal statements with a non-factive operator which suspends commitment to the possible worlds over which the statement to which it is prefixed quantifies. Much as prefixing 'According to Genesis 19:26' to 'Lot's wife was turned into a pillar of salt' produces a compound statement which we may assert and believe without committing ourselves to the actual occurrence of the saline transformation of which the component purports to speak, so – the fictionalist proposes – we may seal off the unwanted ontological commitment carried by $\exists w \mathrm{P}^{*} w$ (the possible-worlds version of $\Diamond p$) by prefixing it with 'According to PW,…,' where 'PW' denotes some suitable version of possible-worlds theory (such as Lewis's).

It is far from clear that embedding possible-world paraphrases of modal statements really does leave us with a theory which enjoys all the supposed advantages of Lewisian realism.[32] Even prescinding from worries on that score, however, the proposal appears to fall foul of a simple dilemma. Observe first that regardless of whether he accepts the conditional 'If PW were true, it would be true that *A*' as a fully adequate explanation of what is meant by 'According to PW, *A*,' the fictionalist can hardly deny that each entails the other; or, if he does, then pending an explanation of what he does mean by the latter there is no theory to discuss. The whole point of fictionalism is, of course, to keep open the option of accepting fictionalized versions of quantifications over possible worlds, whilst rejecting the modal realist's ontology, or at least going agnostic. For simplicity, let's suppose the fictionalist wants to go atheist. So he thinks that PW is false. So, does he think it is contingently false, or that it is necessarily false? If the latter, then he runs into trouble immediately – whatever modal statement *p* is, his replacement for its possible-world translation is going to be vacuously true, simply by virtue of the necessary falsehood of its antecedent. If, instead, he opts for the view that PW, though false, is no worse than contingently so, he must hold that PW might be (or might have been) true. The problem now is to see how this claim, that possibly PW is true, is to be understood. Obviously it cannot be understood in the fictionalist's preferred manner; replacing it by a fictionalist ersatz of the usual kind gives us: 'If PW were true, then there would be a world at which PW is true.' Since this is a direct consequence of 'If PW were true at the actual world, it would be true at the actual world,' it would be true, as would the latter, even if PW was necessarily false. But then the paraphrase can scarcely be held to capture the content of the claim that PW is possibly true. However, if there is some other way to understand this particular modal claim, equally free of commitment to suspect ontology, then it is unclear why modal claims quite generally should not be understood in that way, with the upshot that fictionalization loses its point.[33]

Both of the proposed alternatives to Lewis's realism just discussed make one very important concession to it, namely that ordinary modal idioms are best understood in terms of

quantification over possible worlds (though as noted, the fictionalist, at least, appears obliged to recognize a use of some modal idiom which cannot be reduced to such quantification). It is far from clear, however, that so much should be conceded. Several writers have advocated semantical accounts of modality on which modal adverbs are treated as what surface syntactical form suggests they are, that is, a species of sentential operator. These accounts typically take the form of showing how a truth-theory for an object-language including modal operators may be constructed in a metalanguage which itself contains either those same operators (in which case the relevant clauses can be homophonic) or counterparts which are direct translations of the object-language operators (cf. Peacocke, 1978; Davies, 1981, part III; Forbes, 1985; 1989). Lewis has not, as far as I know, explicitly criticized this approach, but it is not hard to guess at his most likely response. In *Counterfactuals* (Lewis, 1973) he asks: 'If our modal idioms are not quantifiers over possible worlds, what else are they?' and takes it, apparently, that there are just three significantly different alternatives: (1) to take them as unanalyzed primitives, (2) to interpret them as metalinguistic predicates, analyzable in terms of consistency (for example, 'Possibly p' means that p is a consistent sentence), and finally (3) to take them as quantifiers, but ones ranging over a domain of some kind of Ersätze, such as maximally consistent sets of sentences. Options (2) and (3) fall, he thinks, to the objection that they simply give incorrect results unless 'consistent' is understood as 'possibly true,' in which case the theory is circular; (1) he dismisses as "not an alternative theory at all, but an abstinence from theorizing" (Lewis, 1973, p. 85). The force of the circularity objection may be doubted, since we have no right to expect philosophically interesting notions always to admit of fully reductive analyses; and there is, in any case, some question whether Lewis is well placed to press it, since he appears himself to have to rely upon an unanalyzed notion of possible world.[34] He might rejoin that whilst 'possible world' is indeed a primitive for him, the notion receives elucidation via its deployment in his theory in a manner akin to that in which it is commonly held that theoretical terms in natural scientific theories do. But this is unconvincing. Whatever its technical utility, possible-worlds theory holds out little promise of illuminating answers to the philosophical questions about necessity and possibility which exercise us: What is the source or ground of possibility, and how in general do we get to know about it?

3.4 Objections to Lewisian Realism

A viable alternative to Lewis's realism, perhaps along one of the lines we have considered, which can match whatever explanatory virtues may legitimately be claimed for it would undermine Lewis's main argument for his position; but that would not, of course, constitute a direct argument against it (although some, keen to wield Occam's Razor, might see it as a strong indirect argument). There can be no doubt, however, that the principal spur to attempts to develop such an alternative has been the conviction that full-blooded realism should be avoided if at all possible. The sources of this conviction are many and various. We cannot review them all here, but will conclude this part of our discussion with an examination of one particular line of objection which several thinkers regard as the most important direct argument against Lewis's view, and which, together with Lewis's response to it, broaches questions bearing on wider issues in the philosophy of modality. This is the argument from epistemology. If, as in Lewis's view, we stand in no sort of causal, or other natural, relations with possible worlds other than our own, or with their inhabitants, how can we possibly have knowledge, or even well-grounded beliefs, about them? And if the

truth-conditions of ordinary modal propositions are as the modal realist maintains – that is, if they are most perspicuously set forth by paraphrasing them as quantifications over possible worlds – is not the disastrous effect of modal realism that modal knowledge and well-grounded modal belief are rendered impossible?

If it were, in every case, a necessary condition for X to know that *p* that X's belief that *p* should be caused by (or stand in some other suitably causal relation with) the fact that *p*, then the objection would be decisive. It thus appears that the modal realist must deny that knowledge is invariably subject to such a causal constraint.[35] And his position will be the more plausible if he can furnish independent ground for doing so. Lewis contends that mathematical knowledge affords the desired precedent for rejecting a fully general causal requirement. The causal epistemologist's objection to modal realism runs parallel, he claims, to Benacerraf's celebrated dilemma for mathematical knowledge. This rests upon the idea that there is a head-on collision between the demands of a broadly causal conception of knowledge on the one hand, and on the other, any account of the truth-conditions of mathematical propositions which has them speaking of causally inert mathematical objects (numbers, sets, and so on). It is clear, Lewis thinks, how we should respond to Benacerraf's problem: "our knowledge of mathematics is ever so much more secure than our knowledge of the epistemology that seeks to cast doubt on mathematics," so it is the latter which must go – "Causal accounts of knowledge are all very well in their place, but if they are put forward as general theories, then mathematics refutes them" (Lewis, 1986, p. 109).

It would be a perfectly fair objection to Lewis's response as it stands that it simply conflates mathematics with a certain philosophical account of it, according to which the surface syntax of ordinary mathematical statements is to be accepted at face value, with the consequence that numerals and many other mathematical expressions are to be regarded as genuine singular terms, having reference among abstract objects of various kinds. It is the latter, not the former, which is (supposedly) put in doubt by the causal epistemologist's objection. But waive that: even if the case were soundly made that mathematical knowledge should not be seen as demanding causal connections between knowers and what they know, it might still be objected that there is a crucial difference between this case and modality as the modal realist conceives it. Lewis recognizes this: the mathematical objects of which we have knowledge, for all our lack of causal acquaintance with them, are abstract, whereas other possible worlds and their occupants are, as Lewis conceives them, no less concrete than this world and its occupants. There is, then, space for the counter that it is precisely and only because mathematical entities are abstract that we should not expect mathematical knowledge to satisfy a causal condition, so that the suggested precedent is not enough to get the modal realist off the epistemological hook (Lewis, 1986, p. 110). Lewis's response is, in effect, that this mis-identifies what it is about the mathematical case that warrants suspension of causal requirements on knowledge:

> causal acquaintance is required for some sorts of knowledge but not for others. However, the department of knowledge that requires causal acquaintance is not demarcated by its concrete subject matter. It is demarcated instead by its contingency.… [Perception and] other channels of causal acquaintance set up patterns of causal dependence whereby we can know what is going on around us. But nothing can depend counterfactually on non-contingent matters.

Among the non-contingent matters are what mathematical objects there are, and likewise, what possibilities there are. And this is why the imposition of a causal constraint is inappropriate in both cases alike (Lewis, 1986, p. 111).

Even if Lewis's claim about how the area within which imposition of a causal constraint upon knowledge should be demarcated is correct, and even if, further, his main argument for realism from its alleged explanatory advantages is successful in its own terms, there would still be room to question whether he has done enough to see off the epistemological challenge. He would have done so only if the latter argument justifies us in taking claims about what possible worlds there are, and what they are like, to report non-contingent matters, and it is far from evident that it does so. It might, to be sure, be held that statements about what is necessary or what is possible (at least, when broadly logical modality is in question) are themselves, if true at all, necessarily so (as in the modal logic S5). But again, that is not enough for Lewis; the issue concerns the modal status not of ordinary modal claims themselves, but of their construals as quantifications over possible worlds as Lewis understands them. Even if it is allowed that an argument to best explanation may warrant taking such claims to be true, it is hard to see how it could justify us in taking them to be *necessarily* true.

Lewis's claim that what marks off the area within which knowledge should satisfy a causal constraint is not concreteness but contingency is plausible, and coheres with a plausible explanation why the line should be drawn where Lewis proposes to draw it. Satisfaction of a causal constraint is to be looked for just when there can, but need not, be a significant covariation between our beliefs and the facts which confer truth or falsehood upon them. Since non-contingent matters are precisely ones which could not have been otherwise, any counterfactual conditional hypothesizing the falsehood of a non-contingent (that is, a necessary) truth must be vacuously true, whatever its consequent says, for example about what we would then have believed. But then there can be no significant covariation between the non-contingent facts and our beliefs about them, so there is no sense in requiring that they stand in an appropriate causal relation.

Plausible it may be, but the claim is not beyond question. Indeed, if Kripke and those who follow him are right in their claim that there are necessities – such as that water is H_2O and that heat is mean kinetic energy – which can be known only *a posteriori*, then it appears to be mistaken. Such apparent counter-examples might be explained away by maintaining that a different notion of necessity is involved in them, but it is not easy to see independent grounds for supposing that to be so. A more plausible reaction would be to modify the principle of demarcation to something along these lines: causal constraints upon knowledge are inappropriate when we are concerned with necessities known, or knowable, *a priori*. But that suggests that the initial emphasis on non-contingency as such was misplaced, and that the important contrast here is not between necessity and contingency, but between *a priori* and *a posteriori* knowledge. That is, it is a truth's being known independently of experience (however that notoriously problematic notion is precisely to be characterized) that renders inappropriate the demand that our knowledge of it should satisfy a causal constraint.[36] It might be suggested that from this improved perspective, Lewis's arguments from explanatory virtue would, other things being equal,[37] be better suited to their purpose than our preceding remarks suggest. There is, it might be claimed, no evident reason in principle why the explanatory virtues of a realistic attitude towards possible worlds should not lie in its underpinning independently plausible analyses of counterfactuals, propositions, and other *a priori* matters. But this sanguine response overlooks a crucial distinction: it may be that there could be a successful argument from explanatory virtue for something which is in fact knowable *a priori*; but it obviously fails to follow from this, and is anything but clearly true, that such an argument could itself provide us with *a priori* knowledge.

We have thus far followed Lewis's own discussion of the charge that his position is epistemologically bankrupt largely in presupposing that it will be based upon a causal constraint on knowledge. But it may well seem that his position is in epistemological trouble even if a causalist – or more generally, naturalistic – view of knowledge is *not* assumed. Other worlds, in Lewis's view, are composed of concrete entities possessed of properties and standing in relations to one another of the same general kind as the concrete entities in our world (the actual world). If another world contains knowing subjects anything like us, these subjects know of the doings and undergoings of things in their world much as we know of such things in ours. But because of their utter causal isolation from us, we cannot possibly know of those other worldly goings-on in anything like the ways they are supposed to do, and we must be supposed to know of them in some radically different way. But then whatever account may be proposed, it seems that a yawning chasm is bound to open up between the truth-conditions of ordinary modal statements (as Lewis conceives them) and our knowledge; nothing in the character of our knowledge could in any discernible way reflect the nature of the states of affairs which confer truth upon the propositions known.[38]

It might be replied that the objection misdescribes the propositional objects of our modal knowledge as they are best conceived on Lewis's view. There would indeed be a serious, and perhaps insurmountable, difficulty if our modal knowledge had to consist, or be grounded at a fundamental level, in knowledge of the doings and undergoings of particular identifiable objects existing in other worlds – at least on the plausible assumptions that such knowledge would require identifying reference to, or thought of, those objects, and that, in case of concrete objects, no such identifying thought is possible that does not depend, ultimately, on the obtaining of causal or other natural relations between thinker and object. But Lewis's view need not take this shape: what we know, when we know that possibly p or that necessarily q, is, in his view, a general proposition: that there is a world having such-and-such a character, or that all worlds satisfy a certain general description. This would be no help, of course, if our knowledge of such general truths had to be grounded in anterior knowledge of truths concerning particular worlds, as would be so if our knowledge that there is a world in which things are thus and so had to derive by existential generalization from the knowledge that things are that way in w_{17}, and our knowledge that in all worlds such-and-such had to be obtained by (ordinary) inductive inference from knowledge of how things are in some finite selection of worlds. It follows immediately that our modal knowledge, as Lewis conceives it, cannot be like our knowledge that there are cities in the United Kingdom with more than two million inhabitants, or other-worlders' knowledge of similar truths concerning their own world. But this is a point he might readily accept: there are other instances – which for present purposes may be regarded as uncontentious – in which our knowledge of general truths is not of that kind. The obvious examples are afforded by mathematics where, on a classical view at least, we may come to know general truths of both kinds by non-constructive methods, such as proof by *reductio ad absurdum*. The parallel with mathematical knowledge is, once again, one to which Lewis himself appeals in this context:

> In the mathematical case, … we come by our opinions largely by reasoning from general principles that we already accept; sometimes in a precise and rigorous way, sometimes in a more informal fashion, as when we reject arbitrary-seeming limits on the plenitude of the mathematical universe. I suppose the answer in the modal case is similar. I think our everyday modal opinions are, in large measure, consequences of the principle of recombination.[39] … One could

> imagine reasoning rigorously from a precise formulation of it, but in fact our reasoning is more likely to take the form of imaginative experiments. We try to think how duplicates of things already accepted as possible … might be arranged to fit the description of an alleged possibility. Having imagined various arrangements – not in complete detail, of course – we consider how they might aptly be described. (Lewis, 1986, pp. 113–114)

As a rough account of the phenomenology of ordinary modal thinking, this is scarcely open to dispute. But anyone who was troubled by the appearance of an uncomfortable gulf between, on the one side, any credible story about how we might get to know, or justifiably believe, propositions about what is possible or necessary, and on the other, their Lewisian truth-conditions, is liable to feel short-changed. The idea that the possibility of unicorns, for example, consists in there being some other possible world in which concrete horse-like entities have concrete horn-like appendages plays no essential part in the plausible part of Lewis's story about the exercise of imagination in tandem with his combinatorial principle. That is an account which anyone could offer, without commitment to realism about worlds, to which that realism is at best a gratuitous addition – at best: the case is arguably worse, since it is hard to see how the imaginative exercises which Lewis plausibly identifies as the source of our modal beliefs could possibly equip us with adequate reasons for those beliefs, if they really carried the ontological commitments he ascribes to them.

4 Modal Realism 2: The Non-cognitivist Challenge

We have not tried finally to resolve the issue of realism about possible worlds. For all the heat – and comparatively little light – it has generated, it is, in a fairly clear sense, something of a distraction from the leading questions identified in §1.4. The sense in which those questions presuppose a realist conception of modality appears not to be Lewis's, but a more modest one; what is at issue is, rather, the existence of a genuine class of truths essentially involving modal notions.[40] Or, to put the question another way, does a correct claim of the form 'Necessarily *p*' state a fact over and above the fact that *p*? Several recent writers, some of them more or less explicitly following a line of thought suggested by Wittgenstein's remarks on necessity in his *Remarks on the Foundations of Mathematics* (Wittgenstein, 1978), are united in advocating a negative answer to this question, whilst differing both in the considerations they adduce in its support and in their positive accounts of the role or function of necessitated judgments.[41] The principal consequence of the negative thesis is that, when we assert it to be necessary that *p*, we are not making any claim (over and above the plain claim that *p*) concerning which there arises any question about how we know it to be true. I shall, accordingly, use the term 'non-cognitivism' to denote the shared negative thesis.

Philosophical doctrines to the effect that the sentences belonging to a given region of discourse do not – syntactical and other appearances to the contrary notwithstanding – genuinely record or misrecord an appropriately corresponding range of facts have, of course, enjoyed a good deal of popularity, especially among philosophers of broadly empiricist sympathies. The obvious examples are sentences used to voice moral and aesthetic judgments. Faced with the more or less manifest inadequacy of attempts to construe such sentences as having naturalistically statable truth-conditions, and the apparently intractable problem of seeing how we might acquire moral or aesthetic knowledge by anything remotely resembling the methods with which – prescinding from radically skeptical

doubts – we feel comfortable in other territory, and unwilling to postulate a special realm of 'queer' facts and a suitably attuned, special mode of cognitive access to match, the option can readily appear attractive of supposing that moral and aesthetic talk is not aimed at describing or 'tracking' moral or aesthetic fact at all, but is best understood in some other way – as expressive of our own moral and aesthetic responses, say, or aimed at influencing the responses and actions of others. While it is clear that they could not be decisive, there is no doubt that similar considerations may play their part in motivating non-cognitivist thinking about modality.[42] We find the same distrust of irreducibly modal fact, and the position derives a good part of its attraction from the perceived inadequacy of attempts to provide a credible epistemology.

One line of thinking here focuses on the role of imagination in the genesis of modal opinion. Very often, we are moved to judge that things must be thus and so by the seeming unimaginability or inconceivability of the opposite. Confronted – to take what is arguably a fundamental kind of case – with what qualifies, by ordinary criteria, as a valid deductive inference, and finding ourselves unable to conceive how the premise could be true without the conclusion being so as well, we move, without much ado, to the belief that we are faced with a necessity. It is hardly surprising that non-cognitivists tend to look askance at this move, the relations between conceivability and possibility and their opposites having long been a matter of philosophical controversy. The non-cognitivist will grant the facts about what we can and can't imagine, and will assure us that he has not the slightest tendency to doubt that if the premise is true, the conclusion is true as well; but he will protest that he cannot see how that justifies a belief that the conclusion *must* be true, if the premise is. The limit of our imagination may well have a part to play in explaining our confidence in certain judgments, but it is just another fact about us: what reason is there to see in it a reliable indication not merely of their truth, but of their *necessary* truth?[43]

It seems clear that the cognitivist should concede right away that the step to necessity from our inability to conceive the opposite is problematic, if only because, in general, our being unable to do something may, so far, be properly explained either in terms of some limitation from which we perhaps contingently suffer, or in terms of impossibility inherent in the task, which our inability merely reflects. But that is not to concede that it is merely a confused and broken-backed attempt to inflate facts about our imaginative limitations into objective necessities. If the move is thought of as supplying our basis for thinking that there are such things as necessities at all, and is supposed to yield infallible access to them, then it surely is hopeless. But the cognitivist need not be committed to the implausible claim that we are equipped with an infallible method of detecting necessary truths. And he can insist that we should separate the question of our grounds for holding that there are necessary truths to be appreciated concerning some matter, from the question of how we may be justified in taking some particular proposition to be necessary. It is, for example, one thing to hold that if a number is prime, it is necessarily so, and another to hold, of some particular number, that it is necessarily prime; calculation may provide us with grounds for the latter opinion, but support of a quite different kind is needed for the former. If the cognitivist can sustain the distinction in general, and can make the case that there are necessities to be discerned, then he may argue that our inability to imagine things being otherwise can be taken as a fallible, defeasible ground for belief in the necessity in particular cases. These are, of course, very big 'ifs.' The present point is simply that, pending some demonstration that they cannot be discharged, considerations of the kind just rehearsed are bound to be inconclusive, and need not dislodge a determined cognitivist.[44]

Progress on the present issue seems unlikely in the absence of some general, agreed criteria for discriminating between cases in which statements concern some genuinely factual matter – in which correctness is properly seen as consisting in conformity with some range of independently constituted facts, which our opinions, as thereby expressed, may be regarded as in some sense tracking – and cases in which this is not so. A proposal very much to the purpose has been elaborated and defended by Crispin Wright, originally in his book on Wittgenstein's philosophy of mathematics (Wright, 1980), subsequently in his paper "Inventing logical necessity" (Wright, 1986), and in his Waynflete Lectures, *Truth and Objectivity* (Wright, 1992). The general idea underlying Wright's proposal is that statements of a given class are properly viewed as (mis)recording genuine matters of fact – or better, as potentially representing objects of knowledge or at least rationally justifiable opinion – only if there are, *a priori*, certain kinds of limitation on the possibility of intelligible but unresolved disagreement over their truth-values. (See Chapter 20, REALISM AND ITS OPPOSITIONS, §5.) Roughly, the thought is that where A is a statement of the kind in question, such disagreement is intelligible only if traceable to the operation of what can be regarded as a cognitive shortcoming in at least one of the parties to it. Besides omitting important refinements, this way of putting it is, of course, objectionably circular. Here is a more careful formulation, taken from the 1986 paper mentioned above:

> Statements of a certain class are apt for the expression of genuine matters of fact only if there are contexts – in which vagueness, or permissible differences in evidence thresholds, are not to the point – in which it is *a priori* that differences in opinion concerning one of the relevant statements can be fully explained only by disclosing … some material ignorance, error, or prejudice on the part of some or all of the protagonists.[45]

How, assuming its approximate correctness, does this criterion bear on our present question? It may at first appear that, in contrast, for example, with claims about what is funny or boring, where we are happy enough, on occasion, to write off differences of opinion as due simply to diverging tastes or interests, its application would favor the *cognitivist* about modal matters rather than his opponent. But, as Wright argues, matters are not so straightforward. Can we not conceive of a supremely cautious thinker who agrees with the rest of us on all relevant non-modal matters, but consistently balks at the point where we are disposed to judge something to be not just true in fact, but necessarily so? Suppose, then, that we find ourselves locked in apparently intractable disagreement with such a character over, say, the necessity of the conditional corresponding to some simple deductive inference, the correctness of which is agreed on both sides. Neither party, it seems, is under any misapprehension of the exact character of the formal transition in question, and both, it seems, are competent in the use of the logical vocabulary involved. Is it *a priori* that the persistence of our disagreement must, sooner or later, succumb to explanation which convicts him, or us, of some germane ignorance, error, or prejudicial assessment of the data? If not, then the non-cognitivist may claim victory. And since the intelligibility of such a disagreement appears not to depend on anything special to our chosen case, it appears that our cautious individual will be at the service of the non-cognitivist in all cases in which we are disposed to think ourselves confronted with a necessary truth (see Wright, 1986, pp. 202 ff.).

Actually, that final move, to a globally cautious stance on necessity, is very much open to question. If the argument which Wright himself develops against Quine's global empiricism (sketched in §2.3) is good, it establishes that there is no coherent epistemology which does

not acknowledge some judgments – centrally, judgments about what a given empirical theory plus logic entails – as *a priori*. And if that is so, the question arises of how the possibility of acquiring reason to believe such judgments *a priori* is to be explained. But then, as Wright himself puts it, "What better basis on which to found a satisfactory account of the possibility of arriving at certain truths by pure thought than on the notion that they hold true in all thinkable circumstances?" (Wright, 1989, p. 223) (that is, that the truths in question are necessary). It thus appears that there are, after all, reasons to doubt that a globally cautious stance is fully intelligible without supposing its adherent guilty of some cognitive shortcoming: either a failure to acknowledge an indispensable distinction between *a priori* and empirical methods of appraisal, or a failure to appreciate that this distinction issues from the necessity of some judgments and the contingency of others (cf. Wright, 1989, pp. 222–223).

Even if the case just sketched can be made secure, however, cognitivist celebrations would be premature. For on reflection, it seems that an effective case for non-cognitivism might be made *without* relying upon the dubious possibility of global caution. The anti-Quinean argument against the intelligibility of a globally cautious attitude does nothing to establish the unintelligibility of caution in any particular case. Why wouldn't the intelligibility of *local* caution, provided it can strike anywhere, suffice for the non-cognitivist's dialectical purposes? To put the thought another way, why shouldn't the destructive work that was to be done by a single, globally cautious thinker be distributed across a suitably large team of selectively cautious thinkers, each willing to affirm necessity in some cases, while remaining resolutely cautious in others?[46]

There are at least two reasons to doubt that this ingenious twist can accomplish what the non-cognitivist seeks. First, any puzzlement we may have felt about the intelligibility of the globally cautious attitude in relation to particular cases is liable to be compounded by the supposition that caution in selected cases is now coupled with normality (that is, absence of this peculiarly philosophical distaste for modalizing) in others. Are we to suppose, for example, that confronted with *some* valid inferences, our selectively Cautious Man has no compunction in agreeing that their premises necessitate their conclusions, and yet in other cases, simply refuses point-blank to do so, yet without having anything to say in explanation of his peculiar pattern of necessitated judgments? This begins to seem really unintelligible. If, on the other hand, there is some method in his apparent madness, there ought to be something to be said about the principles that inform his selective judgments; and we may suspect that when it is said, we shall be able to locate some material disagreement on other, non-modal matters. This difficulty is, clearly, special to the hypothesis of selective caution; the second, which could as well have been raised in relation to global caution, concerns whether cognitively blameless caution really is a fully intelligible attitude in every case. Suppose, for instance, that the Cautious Man is invited to pronounce upon an explicit formulation of the Law of Non-Contradiction, and responds thus:

> Hm. I am not sure that this is something that I can form a competent opinion about just by reflection. I cannot, I grant, recall any actual example of a statement which was true simultaneously with its negation. And I must confess to some difficulty when I try to be clear about how such a thing might occur. I suspect that it never does occur. Nevertheless, I do not see that this can be a matter for adjudication by *a priori* methods alone.[47]

As Wright observes, this stance is not intelligible. The reason why not is that its intelligibility would require the Cautious Man to believe that some further process is needed to establish

the falsehood of the negation of a proposition, even after the truth of the original proposition had been established – much as, having calculated the value of 10,987 + 3,733, a further process is needed to determine whether it is the same as or distinct from that of 174 × 80. And that, Wright points out, is absurd: "negation is given as a function on truth-value … To suppose that the truth-value of not-*p* may present an *a priori* open question when that of *p* has been settled is merely to display a failure to grasp that negation is, constitutively, a *truth-function*" (Wright, 1989, p. 230).

If this is right, then there are at least some cases in which caution is simply not an option at all, and is therefore unavailable as a means of enforcing a non-cognitivist view of necessity. Clearly crucial questions remain, which we cannot pursue here. So far, it may seem that the non-cognitivist has merely to give up one strategy, but that his position might yet be secured by other arguments. But the damage would be greater, if Wright's criterion could be taken as embodying an acceptable sufficient condition for a statement's enjoying genuinely factual status. For it would then be hard to see how non-cognitivism about a given range of necessitated judgments could be sustained without upholding the intelligibility of the cautious attitude (or something not materially different from it) in those cases. So two pressing questions are: Does Wright's criterion (or some near relative) embody an acceptable *necessary* condition of factuality? and: If so, does it also give an acceptable *sufficient* condition? A third question, which sets the agenda for anyone who hopes to defend affirmative answers to the last two, and is encouraged by the argument of the preceding paragraph, is: How far can considerations of the kind adduced in support of the claim that caution about the *a priori*/necessary status of the Law of Non-Contradiction is incoherent be duplicated in other putative cases of necessary truth?[48]

There have been other challenges to the more modest variety of realism under discussion in this section. Prominent among them is a dilemma by which Simon Blackburn seeks to undermine what he terms the 'truth-conditions approach' to modality (see Blackburn, 1986, pp. 120–121; or Blackburn, 1993, pp. 53–54). Suppose we ask: Why is it necessary that *p*? and receive the answer: Because *q*. Then either *q* will claim just that something *is* so, or that something *must* be so. But if *q* is true but might not have been, then it might not have been true that *p* either – *p*'s supposed necessity is 'undermined.' But if *q* is put forward as necessary, we have either a vicious circle or the start of a vicious regress. We have at best merely explained one necessity in terms of another. But we want to know why anything at all is necessary. Whether this simple dilemma is as effective as Blackburn hopes is a question I must leave the reader to ponder.[49,50]

Notes

1 The case for the indispensability of modal notions may, of course, be argued in other ways. In particular, Timothy Williamson makes a strong case that while most scientific theories are expressible in wholly non-modal language, their application, and in some case their proper interpretation, requires deploying modal notions. See Williamson (2016)

2 For the standard account of relative necessity, see Smiley (1963). Some serious problems for it are raised in Humberstone (1981) (see also Humberstone, 2004).

3 Since state of information varies from thinker to thinker and time to time, the precise import of such epistemic uses of modal idioms would involve also some relativity to context.

4 See, for example, McFetridge (1990, p. 136).

5 Note that this does not amount to assuming comparability with logical necessity and possibility.

6 This argument, and its further significance, are discussed in Hale (1996), and more recently in Hale (2013, §4.3).

7 Dummett (1978, p. 169). The original article appeared as Dummett (1959).

8 "Possibility and necessity" reprinted in Putnam (1983); the words appear on p. 51.

9 Cf. Putnam (1983, p. 53), where Putnam writes: "There is, however, a very different way in which one can try to save the subject of 'necessity' from Quine's attack. Quine, following the logical positivists, assumed that if there was any such thing as 'necessity' then it was either semantical (e.g., 'analyticity') or epistemic ('apriority'). To Saul Kripke is due the honor of introducing into the discussion a very different kind of necessity, an objective non-epistemic kind of necessity: metaphysical necessity. Or so he called it."
In fact, Kripke does not use the term 'metaphysical necessity' in Kripke (1980); but he does contrast the notion of necessity as a metaphysical one with the notions of analyticity and apriority, which he takes to be semantic and epistemological, respectively.

10 Putnam goes on to express some reservations about the strong claim that water is H_2O in all possible worlds, suggesting that "the 'essence' that physics discovers is better thought of as a sort of paradigm that other applications of the concept … must resemble than as a necessary and sufficient condition good in all possible worlds" (Putnam, 1983, p. 64): but he does not see this as undermining the response to Quine's attack.

11 Kripke's idea – his simple inferential model – is taken up and further developed in Hale (2013, §11.2 ff.).

12 It should perhaps be stressed that the point here is purely epistemological – that *a posteriori* knowledge of (metaphysical) necessities depends upon *a priori* knowledge of what would normally be taken (by anyone who has a use for the notion) to be conceptual necessities. It does not appear to require the claim that metaphysical necessity can be analyzed in terms of conceptual necessity – though of course, if such an analysis could be provided it would supply an independent reason against Putnam's proposal. Alan Sidelle (1989) tries to explain how, compatibly with the view that all necessity derives from conventions, there can be *a posteriori* necessities such as that water is H_2O. His general idea is that such metaphysical necessities are grounded in 'general principles of individuation' which record analytic, conventionally grounded necessities. An example of the latter would be 'If water has a certain chemical composition, it has that chemical composition necessarily.' Sidelle explicitly distances himself from the logical empiricists' thesis that all necessity is analytic, and appears not to view his general principles as providing the basis for an analysis of metaphysical in terms of analytic necessity. Just as well, since the necessity operator governing the consequent in such principles can hardly be regarded as expressing analytic necessity. We cannot here pursue the question of whether he succeeds in developing a viable alternative which does not simply boil down to the Kripkean explanation of how *a posteriori* necessities may be known. If he does, that would provide a third reason why Quine's attack on *a priori* necessity cannot be finessed by Putnam's proposal.

13 For a fuller discussion of the issue, see Chapter 23, ANALYTICITY. A third, and very interesting, attempt to prove that we cannot dispense with the idea that some statements are logically necessary may be found in McFetridge (1990, pp. 153 ff.). McFetridge's argument is discussed and developed in Hale (1999), which is in turn criticized in Ahmed (2000), to which Hale (2000a) replies. I give a somewhat simplified, and perhaps more digestible discussion in Hale (2013, ch. 2).

14 Roughly, strike the best balance between minimizing 'recalcitrance' (clashes between our total set of accepted statements and experience) and maximizing overall simplicity and economy to theory.

15 Note that this is *not* the option of tinkering with the underlying logic.

16 Perhaps with the exception of the special case of *a posteriori* necessities concerning natural kinds, etc.

17 Cf. Wright (1980, ch. 23; 1986), but see also Wright (1989), where Wright acknowledges some significant limitations on the scope for non-cognitivism. See below, §4, especially pp. 827 ff.

18 Or equivalent formulae, such as $\Diamond\Diamond A \rightarrow \Diamond A$ and $\Diamond\Box A \rightarrow \Box A$.

19 We would not expect the converse of the B axiom, i.e., $\Box\Diamond A \rightarrow A$ to be a theorem of any significant modal system. If it were added to S5 as an axiom, we could prove the equivalence of $\Box A$ and $\Diamond A$ with plain A, and so with each other, so that the modal system would effectively collapse down to its underlying non-modal logic.

20 For a classic discussion, see Lemmon (1959), which argues that no single system is correct – rather, which system is correct depends upon how the notion of necessity is understood. But even when a more or less definite kind of necessity is understood, there may be serious disagreement. For example, some have argued that the right modal logic for metaphysical necessity is S5; but others have argued that even the weaker system S4 is too strong. See Williamson (2013, ch. 3), Hale (2013, §5.4); but contrast Salmon (1989) and further work there cited.

21 The idea is often thought to come from Leibniz. But as far as I know, although Leibniz famously held that God made actual the best of all possible worlds, he nowhere explicitly proposes to explain necessary truth as truth at or in all possible worlds.

22 Cf. Wittgenstein (1961, §1.1): "The world is the totality of facts, not of things."

23 The lack of fit between the paraphrase argument and Lewis's prevailing conception of worlds is noted in Haack (1977) and Richards (1975).

24 Lewis (1973, p. 86). The objection has no force against the Tractarian conception of possible worlds which best fits the paraphrase argument.

25 For the details of Lewis's account of the truth-conditions of counterfactuals, see Lewis (1973, ch. 1). For a detailed account of what he takes to be the distinctive explanatory pay-offs of his modal realism, see Lewis (1986, ch. 1).

26 According to this analysis, each world is, from the standpoint of its inhabitants, the actual world, and other worlds are merely possible, much as 'here,' as employed by a given speaker, denotes where she is, and any other place is, for her there, elsewhere. Just as none of us is tempted to think that here – where we are currently – is the only place, so no one should be tempted to suppose that this world – the actual world, from our point of view – is the actual world. Being real is not to be identified with being actual.

27 It is fairly clear that Stalnaker takes properties to be abstract entities. Actually he says, rather unfortunately in my view, that they are abstract objects. This might suggest that he thinks that the actual world is, by contrast, a concrete object. Perhaps this way of making the contrast between the actual world and merely possible worlds could be sustained, if we thought of David Lewis and his surroundings as some kind of physical aggregate, as opposed to a set or collection. But it seems best to understand Stalnaker's view as being that possible worlds are properties, each of which might have been instantiated by the actual world, but only one of which is – the way things are.

28 Stalnaker's noted tendency to regard properties as (abstract) objects may partly account for his failure to remark on this point. It is not quite clear that possible-world quantifiers would have to be higher than second-order. Certainly if W is a predicate specifying a way things might have been, there is no evident reason why W should not involve quantification over first-level properties (i.e., properties of individuals), over properties of such properties, and so on, up to quantifications of arbitrary finite order. But this does nothing to prevent W from expressing a first-level property (which the actual world either has or lacks), any more than the higher-order quantification embedded in 'has all the qualities of a great general' prevents it from standing for a first-level property.

29 See McGinn (1981, p. 159). McGinn raises other objections which will not be discussed here.

30 For defense of analyses of propositions as sets of worlds, see Lewis (1986, ch.1) and Stalnaker (1984). The preceding sentence in the text indicates one potentially lethal objection. The issue cannot be pursued here.

31 Cf. Rosen (1990). Rosen's enthusiasm for the position has since been somewhat dampened – see Rosen (1993), and Brock (1993) for a similar problem. Others have been unpersuaded by the objection – see Menzies and Pettit (1994) and Noonan (1994).

32 For argument to the contrary, see Divers (1995).

33 This difficulty is elaborated in Hale (1995b). Rosen seeks to meet it in Rosen (1995), to which Hale (1995a) replies. The dilemma is further discussed by Daniel Nolan (2016), who finds it unconvincing.

34 Added 2014: This strikes me now as somewhat unfair, given that Lewis (1986) at least purports to provide a reductive explanation of what possible worlds are in non-modal terms. Whether the attempted reduction is satisfactory is, of course, a further question. For some discussion, see Divers (2002, ch. 7), Divers and Melia (2002), and, for a somewhat opposed view, Hale (2013, ch. 3)

35 This is a very strong assumption. There is, plausibly, reason enough to reject it, independently of the case in hand – it is, for example, difficult to see how it could fail to preclude the possibility of knowledge of, or justified belief in, perfectly ordinary empirical general truths (see, e.g., Hale, 1987, ch. 4, esp. pp. 92–101). But the difficulty can be put, as Hartry Field has observed in connection with mathematical knowledge (see Field, 1989, pp. 230–239), without relying on any such contentious claim about the analysis of the notion of knowledge. The modal realist should agree that we enjoy a significant degree of reliability in our modal beliefs – that we are fairly good at forming beliefs which accord well with the modal facts. On his view, this consists in our being good at forming beliefs which accord well with the facts about what (other) possible worlds there are, and the character of those worlds. If we are thus reliable, this is something which surely calls for explanation. The objection may then be put without appeal to a specifically causal analysis of knowledge or reasonable belief; given our lack of causal or other natural relations to other possible worlds, it is hard to see how any satisfactory explanation of the sort required could possibly be constructed.

36 McGinn (1976) actually proposes an explication of the *a priori*/*a posteriori* distinction in just such terms. It is important here not to forget that the kind of causal constraint in question is a strong one, to the effect that there must be a suitable causal relation between the putative knower's belief that *p* and the fact that *p*. Thus rejecting it for a given range of cases is not setting one's face against the possibility of any kind of causal or naturalistic account of knowledge whatever.

37 Whether other things are equal – and, crucially, whether Lewisian realism really does enjoy a distinctive advantage in such matters – is, of course, a further question.

38 McGinn (1981, pp. 153–158) develops an objection along these lines.

39 "Roughly, the principle is that anything can coexist with anything else, at least provided they occupy distinct spatio-temporal positions. Likewise, anything can fail to coexist with anything else" (Lewis, 1986, p. 88). Lewis is not committed to this initial formulation – it requires, in his view, a proviso to the effect that recombinations must be consistent with 'some possible size and shape of spacetime' (Lewis, 1986, p. 90).

40 This conception of modal realism is emphasized in, for example, McGinn (1981).

41 Thus Blackburn (Blackburn, 1984, ch. 6.5) depicts modal judgments as expressive of attitude, or something like an attitude; Wright (1980, ch. 23) explores the idea that they record decisions; while Craig (1985) speaks in terms of endorsement of a policy. Wright's position undergoes some shift in Wright (1989), where he grants that necessitated judgments are (at least minimally) truth-apt.

42 As they have in fact played. Blackburn's dilemma at (1986, p. 120) appears to be underpinned by unwillingness to accept irreducible modal facts; the epistemological motive is to the fore in Craig (1985).

43 Cf. Craig (1985, p. 93): "The limit of his imagination … is still just another fact about him, and he sees no reason to take it as a guide to what must of necessity be the case"; and Wright (1980, p. 453): "… you are asking me to affirm that whenever exactly the specified sequence of transformations is correctly followed through on exactly the specified basis, we are bound to achieve this (sort of) result – that no other outcome is possible provided the blueprint is correctly implemented. And that very strong claim, I feel, I am not entitled to make." It is true that Craig and Wright are here describing the position of the Cautious Man – an invention of Wright's, designed to unsettle cognitivists – not that of the non-cognitivist as such. But on the material point – that

the uncontroversial facts cannot rationally warrant a judgment of necessity – their views coincide; they differ, principally, in that while the Cautious Man thinks this obliges him to refrain from making necessitated judgments altogether, the non-cognitivist takes it to show that such judgments are not recognitional, but are to be understood as expressing or endorsing a policy or decision of some sort.

44 See Yablo (1993) for an excellent discussion of the standard objections to treating conceivability as a ground for possibility.

45 Wright (1986, pp. 199–200). For an earlier version of Wright's criterion, see Wright (1980, pp. 448–449). The reference to ignorance and error in the *explanans* should be understood, of course, as relating to ignorance or error about matters recorded in statements lying outside the disputed class – else the criterion would be hopelessly circular. Note that these may include facts about the meanings of relevant expressions.

46 Wright suggests, not a series of selectively cautious thinkers as here, but a single Eccentric Modalizer (cf. Wright, 1989, pp. 225–228). But so far as I can see, the net effect is the same, as are the problems with the suggestion.

47 This formulation is taken from Wright (1989, p. 229), as is the argument that follows.

48 For some – dare I say it? – cautious steps towards an answer to this third question, see the closing nine pages of Wright (1989).

49 For some argument to show that it isn't, see Hale (2002b), Cameron (2010), and Hale (2013, pp. 91–97).

50 Thanks to Crispin Wright and Nick Zangwill for very helpful comments on the original chapter, and to Jess Leech for helpful suggestions about updating it.

Postscript

BOB HALE

The metaphysics, epistemology, and logic of modality are all areas in which much good and interesting work has been done in the two decades since this chapter was first put together. It will not be possible to comment on it more than cursorily. Some of it is the subject of newly added chapters (see Chapter 32, RELATIVISM ABOUT EPISTEMIC MODALS; Chapter 37, TWO-DIMENSIONAL SEMANTICS). This postscript discusses what the present writer views as some of the most important developments, as well as plugging some of the gaps left open in the original chapter.

The Source of Necessity and Possibility

If the various challenges to modal realism in our second sense (see p. 820) can be met, Dummett's questions (see p. 820) must be faced. His first question *can* be interpreted in a reductive spirit, as asking for an explanation of modal notions, or modal facts, in non-modal terms. When it has been so understood, the answers which have commanded most support are two.

First, there is the conventionalist answer which Dummett discusses in the article from which our quotation is taken, and the somewhat more general and looser 'linguistic theory' of necessity of which it is, perhaps, the sharpest formulation. According to this answer, necessary truths are truths guaranteed, somehow, by the meanings of the words we use to express them. Vixens cannot but be female because being female is simply part of what is meant by the word 'vixen.' And since the meanings of words are somehow a matter of convention – either explicit conventional stipulation or, perhaps more likely, tacit agreements put in place by speakers seeking to match their usage to that of their fellows – necessary truths may be held to be the product of such conventions. This kind of theory was at its most popular in the heyday of logical empiricism. It declined in popularity as the leading doctrines of that philosophy, and centrally, the notions of analytic truth and meaning, came under pressure, as well as being the target of direct attacks, first by Quine and subsequently by Dummett, which seemed to show that it must run into a vicious infinite regress. It clashes head on with the widespread acceptance, largely as a result of Kripke's lectures *Naming and Necessity*, of *a posteriori* metaphysical necessities such as 'Water is H_2O,' 'Gold is the element with atomic number 79,' and so on. But it continues to enjoy some support.[1]

Second, there are attempts to furnish a reductive explanation of modality in terms of possible worlds. Reduction requires that what constitutes a possible world be explained in wholly non-modal terms. Lewis's theory, discussed above, aims to meet this requirement

by taking a world *w* to be a spatio-temporally closed system of things – that is, anything spatio-temporally related to anything in *w* is itself in *w*, and nothing else is in *w*. The theory asserts that there is a huge number of such worlds – according to Lewis, at least $2^{2^{\aleph_0}}$ of them.[2] If the purported reduction is to have any plausibility, sheer numbers are clearly insufficient – the possible worlds postulated must differ from one another in ways which are plausibly sufficient to 'cover all the possibilities,' as we might put it. Lewis's theory seeks to achieve this by postulating worlds in accordance with a principle of recombination. So too does the alternative combinatorial theory, which purports to avoid the kind of extreme realism about worlds Lewis advocates, put forward by David Armstrong (see Armstrong, 1989). Very crudely, a *combinatorial* theory holds that the actual world is composed of some – a large number – of fundamental bits and pieces of some sort, and that any way of rearranging, or *recombining*, these bits and pieces constitutes a possible world. Lewis's and Armstrong's theories differ over what the fundamental bits are – for Lewis they are mereological atoms, or individuals, while for Armstrong they are 'thin particulars' and 'fundamental properties.' They agree in holding that any rearrangement of the fundamental bits gives us a world. Underpinning combinatorialism, for both Lewis and Armstrong, is an endorsement of a form of metaphysical atomism – a Humean denial that there are any 'necessary connections' between 'distinct existences.'[3] John Divers (2002) gives a clear and useful exposition and critical assessment of Lewis's theory (see also Divers and Melia, 2002; 2003).

Essence and Essentialist Theories of Modality

Although Dummett's first question *may* be taken as asking for a reductive account of modality, it is not clear that it *must* be. For one might think that even if there is no non-modal basis to which modal concepts, or modal facts, can be reduced, it may be possible to illuminate the source or ground of necessities and possibilities in general by reference to concepts and facts of a particular kind, even though those concepts and facts are not themselves explicable in non-modal terms. This is, perhaps, the best way to view what I shall call essentialist theories of modality.

An essentialist theory of modality should be distinguished from essentialism, as it is commonly understood – that is, as the doctrine, which goes back in one form to Aristotle, that things have some of their properties essentially, but others merely accidentally. Thus it may be held that Aristotle was essentially a man, but only accidentally a philosopher – he might well have never gone in for philosophy, but it is not possible that he should not have gone in for being a man. An essentialist theory of modality involves a commitment to essentialism, but goes beyond it, by seeking to explain necessity and possibility – or at least metaphysical necessity and possibility – in terms of essence: what is metaphysically necessary is what is true in virtue of the nature (or essence) of things, and what is metaphysically possible is what is not ruled out by the natures of things. Different such theories differ, in part, over how they interpret the *explanans* 'true in virtue of the nature (or essence) of' such-and-such. Broadly speaking, by a thing's nature or essence is meant what it is to be that thing. For example, it might held that to be a natural number is to be either zero or one of the successors of zero, or that to be water is to possess a certain physico-chemical structure, consisting in being composed of molecules in which two hydrogen atoms are bonded with a single oxygen atom.

Proponents of essentialism need not embrace an essentialist theory of modality. They may hold that what it is for a property to be essential to its bearers can be explained in modal terms. For example, the claim that whales are essentially mammals might be explained as equivalent to the *de re* modal claim that $\forall x \Box$(x is a tiger $\rightarrow$ x is a mammal).[4] According to an essentialist theory of modality, this gets things back to front – instead of trying to explain essence and essential properties by means of the usual modal operators, we should reverse the direction of explanation. Thus Kit Fine (see esp. Fine, 1994, but also Fine, 1995b; 1995a) agrees that there is an important connection between essence and necessity, but argues that attempts to define essence and essential properties in terms of *de re* necessity are bound to fail, because essential necessities are 'sensitive to source' in a way that *de re* necessities as such are not. For example, while it is necessary that 17 is a member of the set, {17}, whose sole member is 17, it is essential to {17} that it has 17 as a member, whereas it is not essential to 17 that it belongs to {17} – as Fine would put it, the necessity that 17 belongs to {17} has its source in the nature of the singleton set (or perhaps in the nature of sets in general), not in the number 17 itself. It is part of what it is to be {17} that it has 17 as a member, but it is not part of what it is to be 17 that it belongs to that set. Instead, Fine argues, we should take the notion of truth in virtue of something's nature or essence as basic. If we do so, we may define various kinds of necessity in terms of it. For any given kind of entity, there will be a class of propositions which hold true in virtue of the natures of entities of that kind – for example, we might identify mathematical necessities with those propositions which are true in virtue of the natures of mathematical entities.[5] And then, generalizing, we might identify metaphysical necessities with those propositions which are true in virtue of the natures of some entities or other. If, following Fine, we abbreviate 'it is true in virtue of the nature of x that p' to $\Box_x p$, we can express that it is metaphysically necessary that p by $\exists x \Box_x p$, or – allowing for the possibility that something may be true in virtue of the natures of several things – $\exists x_1, \ldots, \exists x_n \Box_{x_1, \ldots, x_n} p$.

Among the questions any essentialist theory must confront, two obvious and central ones are: Can the basic notion of a proposition's being true in virtue of something's essence or nature be made clear – or at least sufficiently clear to overcome the doubt and suspicion with which many philosophers have viewed it? And, can a theory of this kind meet the general epistemological challenge which, as we have seen, confronts any theory of modality? How is knowledge of essence possible? These questions, along with others they prompt, have been the focus of a significant body of recent work to which we can only allude here.[6]

Modal Knowledge

The epistemological challenge (in effect, Dummett's second question (see §1.4)) is one which any account of the nature and basis of modal facts must confront. It is, as Peacocke points out (Peacocke, 1999, pp. 3–4), a version of the same challenge – the Integration Challenge, as he labels it – as that posed by Benacerraf in the philosophy of mathematics – how to square a believable account of the nature of mathematical *truth* with a believable account of how it is *known* (see Benacerraf, 1973). Much recent work can be seen as attempting to meet it.

As Kant observed (Kant, 1781/1787, p. 43), experience may teach us that things are thus-and-so, but not what must be so. But it can, to a limited extent, tell us what is possible. In some cases, conclusions about what might or can be so may be inferred from entirely

non-modal premises – as the medievals put it, we may reason *ab esse ad posse*. From the fact that Dr Roger Bannister ran a mile in less than four minutes, it follows that it is possible that a human being should perform this feat. Obviously there are countless other conclusions about what is possible which may be inferred from premises about what is actual. But this is knowledge only of *realized* possibilities – the central problem of modal knowledge is to explain how we can have knowledge of *unrealized* ones, together with knowledge of *necessities*. It may be suggested that the *ab esse* route may give us at least some knowledge of unrealized possibilities from non-modal premises – that in some cases, we may argue that this table broke, from which it follows that it was possible that it should break, and putting this together with the additional premise that there are no relevant differences between this table and that other table (which has not broken), we may infer that that other table might break.[7] It is not, without closer investigation, clear that the requisite supplementary premise about absence of relevant difference will prove to be cleanly non-modal. But even if it can be argued to be so – perhaps it can be supported by evidence relating to many tables, some of which were observed to break and others not, and that our candidate table does not differ from those which actually broke in ways in which they do not differ among themselves, and does not differ from them in any of the ways the tables known to have broken do so – it is clear that this kind of inference gives us at best only severely limited knowledge of unrealized possibilities, namely possibilities of *kinds* which are realized. There is no prospect of its getting us to metaphysically interesting unrealized possibilities, such as the putative possibility that an individual might have had different origins, or have been composed of entirely different matter, or have been a frog rather than a man.

To get beyond this crippling limitation, some other approach is needed. Many, if not all, recent approaches can be divided into two broad groups – those which see our primary access to modal facts as consisting in recognition of possibilities, and those which see knowledge of necessities as primary.[8] Possibility-first approaches standardly see some form of conceivability as our guide to possibility. A clear example of a necessity-first approach is the simple inferential model of knowledge of necessity proposed in Kripke (1971).

The idea that conceivability or imaginability can give us knowledge of possibility has a distinguished pedigree.[9]A central question for this approach, on which Yablo's seminal paper (Yablo, 1993) focuses, is what we should take to be required for conceivability. A large part of this question concerns what constraints must be met if something is to be conceivable in the relevant sense. Most would agree that the putatively conceivable state of affairs must be specifiable without violating logical laws. But many would agree that this minimum condition is not sufficient. A plausible strengthening is that putative possibilities should be describable without doing violence to the non-logical concepts involved.[10] Taking this to be a sufficient as well as necessary condition for conceivability amounts to equating possibility with what is sometimes called broadly logical or conceptual possibility. Such an equation was made during the first half of the last century by logical empiricists and others who simply identified necessity with analytic truth (including Quine, see n. 4). Since there appears to be no conceptual incoherence in the supposition that gold is a compound or that water is an element, these – the contraries of familiar Kripkean examples of putatively *a posteriori* necessities – would qualify as genuine possibilities. If conceivability is to be seen as a route to knowledge of *metaphysical*, as distinct from merely conceptual, possibility, some further constraints are required.

Constraints which might be proposed include ones concerning a thing's substantial composition or constitution, its membership in some substantial kind, and perhaps its

biological or other origin.[11] The idea would be that facts about some or all of these matters should be held fixed in our attempts to conceive of counterfactual situations. Thus it may be held that if water is composed of H_2O molecules, then it is not properly conceivable that it should have a radically different chemical composition; that given that Aristotle was a man, we cannot properly conceive of him as having been a frog, and perhaps that given that Elizabeth II had her origin in a sperm and egg produced by George VI and Elizabeth Bowes-Lyon, no situation is conceivable in which she has a different biological origin. These constraints are all more or less controversial, the last especially so.

If we ask what might justify imposing such constraints, it is not easy to see what other answer might be given than that substantial composition or constitution, kind membership, and origin, are *essential* or *necessary* to things being the things they are. The fact, if it is one, that justifying the constraints involves appeal to modal facts does not directly show conceivability-based epistemology is not viable, for perhaps we can separate questions about what methods may be employed in acquiring modal knowledge from questions about their justification. But if that justification itself rests on underlying modal claims – about constitution, kind membership, origin, and perhaps other matters – it seems that at least some modal beliefs cannot be justified by facts about conceivability.

The general principles for which justification is required are of precisely the kind required for the development of the alternative, necessity-first, approach – at least if it is to proceed along the lines of Kripke's inferential model (see above §2.2) That is, they are general principles which imply the singular conditionals of the form $p \rightarrow \Box p$ which figure as the major premises for inferences to necessitated conclusions. According to Kripke, these major premises can be known *a priori*, 'by philosophical analysis.' A major task for this approach is to spell out just how, in convincing detail, that philosophical analysis (if that proves to be the best description of it) is supposed to go.[12]

The considerable recent literature in modal epistemology includes much critical discussion of the approaches briefly sketched here. In addition to works already cited, Gendler and Hawthorne (2002) is a useful collection of papers, and Vaidya (2011) provides a useful up-to-date survey.

Necessary and Contingent Existence, Actualism, and Possibilism

Almost everyone agrees that things might have been other than the way they actually are – that there are contingent facts. Many also think that the contingent facts include facts about existence – that at least some of the things which actually exist might not have existed, and that there might have existed things other than those which actually exist. This latter belief, about contingent existence, is known as *contingentism*. Opposed to it stands the view that everything which exists exists necessarily, and that nothing which does not exist might have existed – this is *necessitism*. According to contingentism, you and I, and countless other objects, might not have existed; according to necessitism, we and all other objects necessarily exist. Necessitism appears to fly in the face of common sense – surely you and I and many other things might quite easily not have existed? Necessitists reply by distinguishing between existing and being concrete. It is certainly true that we might not have been concrete embodied persons. But this does not mean that we might not have existed. What would we have been, had we not been concrete? The necessitist view is not that we would have been disembodied spirits. When we are not concrete, we are merely possible people – a

species of merely possible objects, or bare *possibilia*. Possibilism is the view that there are merely possible objects; actualists hold that everything is actual (i.e., that only what actually exists exists).

It will still seem to many that necessitism is an implausible doctrine. But some serious arguments have been advanced in its favor. It cannot simply be dismissed out of hand. One argument is from logical simplicity. It can be argued, plausibly, that the modal logic of absolute necessity should be S5, the simplest, but strongest, normal modal logic. In quantified S5, one can prove the Barcan principle and its converse, which together require that nothing that exists could have failed to exist, and that nothing which doesn't exist could have done so. To be sure, Barcan and Converse Barcan cannot be proved if the underlying logic is free. But necessitists may argue that simplicity considerations weigh against the complications that course entails. Another argument runs as follows: Necessarily, if I don't exist, the proposition that I don't exist is true. Necessarily, if the proposition that I don't exist is true, that proposition exists. But necessarily, if the proposition that I don't exist exists, then I exist. Hence necessarily, if I don't exist then I do exist. Hence, necessarily, I exist. These two arguments along with some others are given by Timothy Williamson.[13] The second has been met with various objections from defenders of contingent existents (see Rumfitt, 2003; Wiggins, 2003; Efird, 2010). Many philosophers find the possibilism necessitism requires unpalatable, and would probably view its implausibility as outweighing the simplicity arguments for necessitism.[14]

Notes

1 Perhaps the most concerted defense is Sidelle (1989), some of whose more recent work, Sidelle (2002), explicitly takes issue with post-Kripkean orthodoxy. Cameron (2010) seems also to advocate a form of conventionalism.

2 That is, at least as many as there are subsets of the continuum, or subsets of the set of all real numbers. See Lewis (1973, p. 90), where Lewis gives the number as at least $\beth_2$, which is the same as $2^{2^{\aleph_0}}$.

3 Cf. Lewis (1986, p. 87), Armstrong (1989, pp. xi–x). As interpreted by Lewis and Armstrong, and perhaps as intended by its author, Hume's denial of necessary connections between 'distinct existences' almost certainly forecloses against any serious form of essentialism (see Chapter 34, ESSENTIALISM, also below). Hale (2013, §3.3) takes issue with it on this ground. Direct reliance on Hume's denial might be avoided by taking a possible world to be any mathematically possible recombination of basic bits; but, setting aside the question whether an appeal to mathematical possibility compromises the reductive aim, it should be clear that the equation of *metaphysical* possibilities with mathematical ones (i.e., combinations which cannot be ruled out on purely mathematical grounds) is equally question-begging.

4 What makes this *de re* is that the necessity operator $\Box$ is applied to an *open* sentence, that is, a sentence containing a free variable. Contrast the *de dicto* modal sentence $\Box\forall x$ (x is a tiger $\rightarrow x$ is a mammal), in which the modal operator is applied to a *closed* sentence, with all occurrences of the variable x bound by the universal quantifier $\forall$. Some philosophers – most notably W. V. Quine (see, e.g., Quine, 1956) – have thought that *de re* modalities are unintelligible, and that we can, at best, make sense of *de dicto* claims because we can construe them as asserting that their embedded (closed) sentences are analytically true. According to this skeptical view, necessity resides in the way we talk about things, not in the things themselves, as Quine once put it.

5 Fine himself characterizes the mathematical necessities as the propositions true in virtue of the nature of the mathematical concepts and objects, and similarly for other kinds of necessity, such as logical necessities. The formulation in the text is better suited to the somewhat different essentialist theory put forward in Hale (2013, ch. 6).

6 In addition to works already cited, Wiggins (1976), Correia (2006; 2007), Shalkowski (1994; 1997), Lowe (2012), and Vaidya (2011) include discussions broadly in sympathy with an essentialist theory of modality or essentialism more generally. More critical discussion can be found in Mackie (2006), Noonan (2013), and Ahmed (2007). See also Della Rocca (1996), Gorman (2005), and Wildman (2013).

7 The example is taken from a paper by Sonia Roca-Royes (2017), who defends a version of this kind of modal empiricism, as she calls it.

8 For this classification, where the approaches are labeled possibility-first and necessity-first, see Hale (2002), which argues for the latter.

9 Most notably, in Descartes and Hume. For Hume, see especially Hume (1960). For Descartes, see, for example, Meditation VI: "First, I know that everything which I clearly and distinctly understand is capable of being created by God so as to correspond exactly with my understanding of it … I have a clear and distinct idea of myself, in so far as I am simply a thinking, non-extended thing; and … a distinct idea of body, in so far as this is simply an extended, non-thinking thing. And accordingly, it is certain that I am really distinct from my body, and can exist without it" (Descartes, 1988, pp. 114–115). Descartes's position is complicated, and arguably rendered inconsistent, by his doctrine that God is the source or creator of all truths, including truths about what is necessary and possible. For some excellent discussion, focused on this problem, see Ian McFetridge's posthumously published, but sadly incomplete, essay "Descartes on modality" McFetridge (1990). A very useful commentary on Descartes's crucial letter to Mesland of May 1644 occurs in Anfray (2009, pp. 103–124).

10 Cf. Peacocke's modal extension principle (Peacocke, 1997, pp. 526–540; Peacocke, 1999, §4.2). Peacocke does not present his 'principle-based' account of modal knowledge explicitly in terms of conceivability; his idea rather is that our concept of possibility may be captured by a set of principles governing what counts as an admissible assignment of semantic values to concepts, and that our knowledge of possibility may be seen as the exercise of our grasp of these principles.

11 cf. Peacocke's constitutive principle for kinds (Peacocke, 1997, p. 540; or 1999, p. 145). Similar constraints play a key role in the interesting theory developed by Timothy Williamson, according to which knowledge of metaphysical modality can be obtained by essentially the same constrained imaginative procedure as he takes to give us knowledge of ordinary counterfactuals. See Williamson (2007, ch. 5, especially pp. 163–164).

12 Kripke himself supplies more detail in two cases – necessities of identity and (rather more controversially) necessities of origin. Some further attempts in the same direction are made in Hale (2013, ch. 11).

13 Williamson (2002; 1998; 1990; 2013). For a similar view, see Linsky and Zalta (1994; 1996).

14 An impressive defense of contingentism is Stalnaker (2012). Menzel (2014) provides a useful and quite comprehensive survey of the actualism and possibilism.

Relativism about Epistemic Modals

ANDY EGAN

1 Introduction

The paradigmatic instances of epistemic modals are the sorts of uses of "might," "must," and "possible" that occur in exchanges like the following:

> "Where are my keys?"
> "I'm not sure – they might be on the desk."
>
> "Where's Bob?"
> "He must be in his office. His light's on, and his jacket's hanging outside the door."
>
> "Does John have cancer?"
> "It's possible that John has cancer. He has some of the symptoms. They've run some tests, but we won't know the results until tomorrow."

These are uses of "might," "must," and "possible" whose truth is somehow or other bound up with something about somebody's epistemic state. Call these kinds of sentences, in which an epistemic use of "might," "must," or "possible" takes wide scope over an unmodalized clause, *simple epistemic modal sentences*, or *simple EM sentences*.

The overwhelmingly natural first thing to say about just how such sentences are bound up with our epistemic states – one that serves as the point of departure for most of the views about epistemic modals now in circulation in the literature – is that with these sorts of uses of "might," "must," and "possible," a simple epistemic modal sentence of the form *might:P* (or *possibly:P*) is true iff P is compatible with what's known, and *must:P* is true iff not-P is incompatible with what's known. The reason why epistemic modals are interesting, and why it's hard to give a satisfactory theory of them, is that it's remarkably difficult to transform that plausible-looking first shot into a worked-out account.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

The first obvious question to ask about such an account is, "known by whom"? And a brief survey of cases reveals that the answer has got to be, "it depends." A number of authors have presented a variety of cases that demonstrate this. (See, for example, Hacking, 1967; Teller, 1972; Kratzer, 1986; DeRose, 1991.) Here is a somewhat simplified version of one from DeRose (1991):

> *The Cancer Test*
> John's just had a test, a negative result on which would rule out cancer. Jane, not knowing what the results were, says (in response to an inquiry from Bill, who's heard a rumor that John has cancer), "It's possible that John has cancer – they've run a test that could rule it out, but we won't know the results until tomorrow." At the same time, the doctor, who has seen the negative results of the test, says, "it's not possible that John has cancer – we should start planning tests for other diseases."

It seems as if both Jane and the doctor speak truly. A plausible explanation of this is that it's Jane's knowledge that's relevant to the truth or falsity of Jane's claim, and it's the doctor's knowledge that's relevant to the truth or falsity of the doctor's claim. It's easy to construct similar examples for "might" (though it's complicated a bit by the inconvenient fact that there is no lexical item that clearly stands to "might" as "impossible" stands to "possible," which makes the examples a bit less clean).

The lesson that's typically been drawn from these kinds of cases is a *contextualist* one. Different utterances of epistemic modal sentences are responsive to different peoples' epistemic states because they are *about* different people's epistemic states. At a first pass: If Jane says, "John might have cancer," she speaks truly, because what she's said is *that it's compatible with what Jane knows that John has cancer*. If the doctor says, "John might have cancer," he speaks falsely, since what he says is *that it's compatible with what the doctor knows that John has cancer*. This is actually not quite the standard contextualist conclusion. The standard view has it that the relevant epistemic state needn't be the state of some *individual*, but could be (and often is) that of some group or community.

One way to motivate this is by drawing attention to a phenomenon observed by G. E. Moore (1962), in which he notes that it's possible to deny someone else's assertion of "it's possible that Hitler is dead by now" by saying, "I know he's not." It would be odd if an assertion about *my* knowledge could serve to deny your epistemic possibility claim if what epistemic possibility claims assert is just that the relevant proposition is compatible with *the speaker's* knowledge. It's to be expected, though, if what's being asserted is that it's compatible with the collective knowledge of a group to which we both belong. (There are complications about how to understand collective knowledge. See von Fintel and Gillies, 2011, for discussion.)

Another motivation comes from a family of cases discussed by Keith DeRose (1991), which are variations on *The Cancer Test* above. In one such case, Jane knows that the doctors have looked at the test results, but they haven't yet told her about them. Asked, "Is it possible that John has cancer?" she replies, "I don't know whether it's possible that John has cancer; only the doctors know. I'll find that out tomorrow when the results of the test are revealed." Here, it seems clear that the embedded possibility claim can't be about her knowledge – what she doesn't know is whether it's compatible with the doctors' knowledge that John has cancer, so the relevant group must include at least the doctors.

There is another family of examples that motivates variability in whose knowledge is relevant, largely inspired by (or anyway in the spirit of) a footnote in John Hawthorne's *Knowledge and Lotteries* (Hawthorne, 2006). These examples are meant to support the more radical hypothesis that a *single utterance* can be correctly evaluated as true by one assessor, and correctly evaluated as false by another, because the epistemic states that are relevant to correct evaluation are different for the two assessors. These kinds of examples figure prominently in the relativist arguments of, for example, MacFarlane (2011; 2014), Egan, Hawthorne, and Weatherson (2005), and Egan (2007).

Here is the relevant footnote:

> [A]s far as I can tell, ordinary people evaluate present tense claims of epistemic modality as true or false by testing the claim against their own perspective. So, for example suppose Angela doesn't know whether Bill is alive or dead. Angela says Bill might be dead. Cornelius knows Bill is alive. There is a tendency for Cornelius to say Angela is wrong. Yet, given Angela's perspective, wasn't it correct to say what she did? After all, when I say 'It might be that P and it might be that not P', knowing that Cornelius knows whether P, I do not naturally think that Cornelius knows that I said something false. There is a real puzzle here, I think, but this is not the place to pursue it further. (Hawthorne, 2006, p. 29, fn. 69)

And here is a case of the sort used in the relativist literature (this one is a modified version of one from MacFarlane, 2011):

> *Eavesdropping Brian*
> The evidence Sally and George have available to them leaves it open that Joe is either in Boston or in Berkeley. Brian, listening in from behind a nearby shrub, just saw Joe in Berkeley five minutes ago. Sally says to George, "Joe might be in Boston." George accepts Sally's assertion, and signals his assent by saying, "that's true." Brian rejects Sally's assertion, and signals his dissent by muttering to himself, "that's false."

George's assent and his attribution of truth to Sally's utterance seem completely in order. So do Brian's dissent and his attribution of falsity to the very same utterance. This suggests that it's not just that different epistemic states can be relevant to the evaluation of different utterances of epistemic modal sentences, but that different epistemic states can be relevant to different assessors' evaluations of the *same* utterance of an epistemic modal sentence. (As mentioned above, these cases are much more controversial than the cases meant to show variation in relevant epistemic state across utterances. We'll talk more about the objections and responses to these kinds of cases, and the arguments based on them, in §5.)

Pretty much all parties to the debate agree that we can't give a uniform, one-size-fits-all answer to the question of whose knowledge is relevant to assessing the truth or falsity of epistemic modal claims. Many also question whether it's really always *knowledge* that's at issue, or whether we should allow the relevant epistemic relation to vary as well. Here is a case from Hacking (1967):

> *The Salvage Ship*
> Imagine a salvage crew searching for a ship that sank a long time ago. The mate of the salvage ship works from an old log, makes some mistakes in his calculations, and concludes that the

> wreck may be in a certain bay. It is possible, he says, that the hulk is in these waters. No one knows anything to the contrary. But in fact, as it turns out later, it simply was not possible for the vessel to be in that bay; more careful examination of the log shows that the boat must have gone down at least thirty miles further south. The mate said something false when he said, "It is possible that we shall find the treasure here," but the falsehood did not arise from what anyone actually knew at the time. (Hacking, 1967, p. 148)

Cases such as Hacking's suggest that we sometimes want a relation *weaker* than knowledge, so that sometimes what's relevant to the truth or falsity of an epistemic modal claim is not what we *know*, but, for example, what we could come to know by some available method of inquiry. (Other cases – some of which are discussed in Dever (2013) – suggest that we sometimes want a relation *stronger* than knowledge, such that not everything that we know will always be relevant.)

In general, the truth or falsity of epistemic modal claims depends on the compatibility of the embedded proposition (the *prejacent*) with some body of information – the information that's within the epistemic reach of some person or group. Which person or group's epistemic reach is relevant, and what it takes for some piece of information to count as within a person's or group's epistemic reach, seems to be variable, varying at least with the context in which epistemic modal claims are made, and possibly also with the context in which they're assessed. This is why it's so difficult to turn the promising first shot at the truth-conditions of epistemic modal claims – that, for example, *might:P* is true iff P is compatible with what's known – into a worked-out theory.

One way to deal with this, and to allow for variation in which body of information is relevant, is to go contextualist, and to say that the relevant body of information is determined by the situation of the *speaker* – by the person who's uttering the sentence. Another is to go *relativist*, and say that the relevant body of information is determined by the situation of the *assessor* – by the person who's assessing the sentence for truth or falsity.

Our main focus here will be on relativism, and my goal here will be to put on clear display the outlines of the debate about relativism about epistemic modals. But it will be helpful to say a bit more about the structure of contextualist theories, since contextualism is the main competitor to relativism, and probably is (and ought to be) the default starting-point view. Accordingly, much of the motivation for relativism comes from the purported inadequacy of the contextualist options.

Two notes about things I won't do in what follows, before we move on:

First, there are (at least) two other options, which I won't discuss here for reasons of space. One option that's very much alive is to go with a theory according to which epistemic modal claims aren't in the truth and falsity business. (For advocacy of such proposals, see Yalcin, 2007; 2011; Swanson, 2011.) Another thing to notice is that both relativist theories and standard contextualist theories assume quite a close connection between semantic content and communicative import. We could go with a theory that separates these quite sharply, as do the sorts of *pluralist* theory offered (though not specifically about epistemic modals) by Cappelen and Lepore (2005), or the sort of propositional radical theory offered by Bach (2011).

Second, I'm going to follow the literature by focusing almost entirely on "might" and "must" – and much more heavily on "might" than "must." But it's worth bearing in mind Eric Swanson's (2011) warning that "might" and "must" are just two examples of a much broader category – the category Swanson calls "the language of subjective uncertainty" – which it would be nice to have a unified account of, and that there are theoretical risks associated

with focusing too hard on a limited range of examples. I will run these risks here in the interests of space and ease of presentation, but it's worth bearing them in mind as we move along.

In the next section, we'll look at some of the important features of contextualist views in general. We'll then look, in §3, at contextualist views about epistemic modals in particular. In §4, we'll discuss the internal workings of two different sorts of relativist theories. In §5, we'll discuss some standard arguments relativists have deployed to motivate relativism over contextualism, and we'll trace a few of the first steps of the ensuing dialectic of reply and objection. In that section, we'll look at a number of the standard replies to relativist arguments. At more or less every point in what follows, I will, unavoidably, leave out a lot. Rather than trying to lay out all of the fine details of the various branches of the dialectic, I'll be concerned primarily to lay out the central moving parts of the main positions in debate and to walk through the first few steps of the core arguments.

2 Contextualism

The following diagram (Figure 32.1) illustrates the more-or-less standard picture of how sentences and utterances come by their truth-values. (The canonical source of this picture is, of course, Kaplan, 1989. See also Lewis, 1980.)

A sentence is associated, in the first instance, with a *character*, which determines a function from contexts of utterance to contents expressed. (It's more standard to talk about the characters of lexical items than of sentences. But it's easy to assign a character to a sentence based on the characters of its constituent expressions.) A sentence that doesn't include any context-sensitive vocabulary will have a constant character – it will express the same content in every context of use.

Assigning truth-values to sentences in a context of utterance is a two-step process: first, the context of utterance serves as an input to the sentence's *character*, in order to determine a content. Then the *circumstance of evaluation* (or *index*) corresponding to the context of utterance serves as the input to the contextually determined content, in order to determine a truth-value. So the truth-value of a sentence in a context, or of a particular token utterance, is sensitive to the context of utterance twice over: first, as an input to character, and second, as the determinant of which index serves as the relevant input to content.

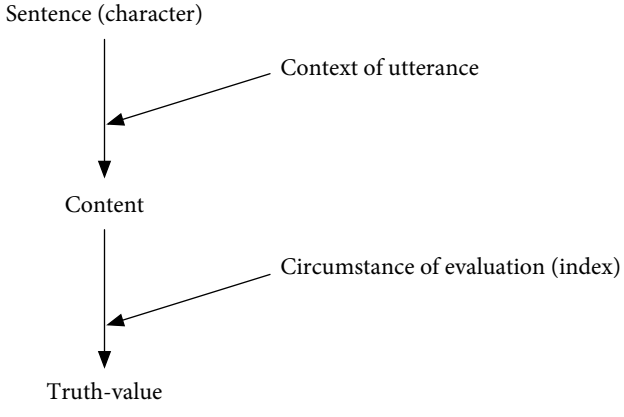

Figure 32.1

The key feature of all of this for our purposes is that standard contextualist views deliver a single, once-and-for-all verdict on the truth-value of a sentence in a particular context of use, and (therefore) on the truth-values of particular token utterances. While different utterances of the same sentence can take different truth-values, a particular, dated, world-bound utterance gets a truth-value *simpliciter*.

(I am going to assume – as I did above – that it's safe to move smoothly between issues about the assignment of truth-values to *sentences in context*, and issues about the assignment of truth-values to *particular token utterances*. I should note that this is potentially contentious.)

3 Contextualism about Epistemic Modals

There is a widely accepted, received view about the semantics of modals in general, the paradigmatic statement of which is found in Kratzer (1977; 1981). Here is, I think, a pretty uncontroversial, minimally formal way of stating it: The truth of *modal:P* at a world w depends on how things stand with respect to P in the worlds w* that bear some particular relation to w – the w*s *accessible* from w. (More generally, the truth of *modal:P* at an index i depends on how things are with respect to P at the indices accessible from i.) Different species of modality are distinguished by differences in the relevant accessibility relation. So what's nomologically possible in w is what's true in some world that's *nomologically* accessible from w – some world whose history is compatible with the laws of w. What's nomologically necessary in w is what's true in every world whose history is compatible with the laws of w. What's epistemically possible in w is what's true in some world that is, in some sense, *epistemically* accessible from w – plausibly, some world that's compatible with the epistemic state of some selected person or group in w. And so on.

(The above is not quite right: for a number of modals, we need not just an accessibility relation, but something that imposes an ordering on worlds. (See Kratzer, 1981; 1991.) We will ignore this complication in what follows.)

In this sort of framework, the distinction between, for example, metaphysical, nomological, deontic modals isn't a distinction between different sorts of lexical items, but between different kinds of uses of the same lexical items. There's just a single "might" in the lexicon, but it's context-dependent, since the relevant accessibility relation is different in different contexts. Similarly for "must," "possibly," and so on.

The overwhelmingly natural thing to say about *epistemic* modals, given this framework, and the thing we should say unless we're forced out of it, is that they are modals like any other, and context-dependent in just exactly the way that modals in general are context-dependent. Epistemic modals, that is, are just standard garden-variety modals, which happen to occur in a context that provides a distinctive sort of accessibility relation – one that has got something to do with somebody's epistemic state, such that the accessible worlds are the ones that some person or group stands in some particular epistemic relation to.

The simplest sort of contextualist account is probably what MacFarlane (2011; 2014) calls *solipsistic contextualism*, according to which the accessible worlds are those compatible with the speaker's knowledge. It's worth noting that this is a theory that makes decisions at two different choice points. It says that it's the *speaker*, rather than some other person or group, whose epistemic state is relevant. That's captured by calling it *solipsistic* contextualism. It also says that the epistemic relation that's important is *knowledge*, rather than some

other – possibly weaker, possibly stronger, possibly cross-cutting – epistemic relation. Different solipsistic contextualisms could differ on this point. So the view in question is probably better described as *solipsistic knowledge contextualism*.

The cases of variability we looked at in §1 suggest that solipsistic knowledge contextualism can't be right. DeRose's "might be possible" cases, and the facts about disagreement, suggest that the *solipsistic* part won't do, and cases like Hacking's suggest that the *knowledge* part won't do, either.

It should be clear, though, that solipsistic knowledge contextualism isn't the only option available for a contextualist about epistemic modals. There's a *lot* of room for variation in the story about just which people or groups, and which epistemic relations, are relevant, and in which circumstances. Pick any group, and any epistemic relation, that you like, and there's an accessibility relation that tracks what's compatible with what that group stands in that epistemic relation to. There is a lot to say about contextualism-internal debates about just which persons, groups, and epistemic relations are potentially relevant, and just how the relevance of a person, group, or epistemic relation depends on other features of the context. But what's important for our purposes is just the fact that contextualism offers quite a versatile framework for fleshing out the details of a theory of epistemic modals.

On our working contextualist theory, there will be two relevant contextually variable moving parts: the relevant group, and the relevant epistemic relation. An utterance of "Bob might be in his office" will always express a proposition of the type, *that it's compatible with all of the evidence that G stands in R to that Bob is in his office*, but it will express different such propositions in different contexts of utterance, because different Gs and Rs will be relevant in different contexts. The proposition that's expressed, that is, is a proposition about some person or group's epistemic state. It's true in worlds where the contextually relevant group fails to stand in the contextually relevant epistemic relation to evidence that rules out Bob's being in his office.

To sum up: this is a view according to which *epistemic* modals are just regular, garden-variety modals, used in a context that provides a certain distinctive kind of accessibility relation. What's distinctive about them is that their accessibility relations are ones that track what some person or group stands in some epistemic relation to. This allows for a lot of internal diversity within the category of epistemic modals, depending on whose epistemic reach the accessibility relation is tracking, and on what kinds of standards of *reach* are being applied.

4 Relativist Proposals

There are a number of different relativist views of epistemic modals on offer. All of them are committed to denying that utterances of simple epistemic modal sentences get truth-values "once and for all," and maintaining that a single, dated utterance can be true relative to one context of assessment and false relative to another.

There are two ways to do this. First, one can say that the context of assessment plays a role in the determination of the *content* of the utterance, so that a single utterance can express different propositions to different audience members. Call such views *content-relativist*. (See Predelli, 1996; 1998a; 1998b; Cappelen, 2008a; 2008b; and Egan, 2009, for defenses of such views – though not about epistemic modals.) Alternatively, one can say that the utterance has a single determinate content, fixed by its context of utterance, but that

(a) the content determines a truth-value relative to an index that includes not just a world, but also some further parameter with respect to which two contexts of assessment (within a possible world) might differ, and (b) which such index is relevant to assigning truth-values to an utterance can vary across contexts of assessment. Call such views *truth-relativist*.

I'm going to set content-relativist theories aside at this point, since the proposals about epistemic modals that have been discussed under the heading of "relativism" in the literature are predominantly truth-relativist proposals. So in what follows I'll use "relativist" to mean *truth-relativist*, and the relativist theories I'll be discussing here will all be instances of that type.

The various truth-relativist theories about epistemic modals all do two things, corresponding to (a) and (b) above: First, they postulate a further parameter, in addition to a world (and perhaps a time) in the index, or circumstance of evaluation, relative to which the contents of epistemic modal sentences take their truth-values. And second, they tell a story about the role this extra parameter plays in the notion of utterance truth, and in the practice of evaluating utterances for truth and falsity, such that we get the possibility of one assessor correctly evaluating an utterance as true, while another correctly assesses it is false.

John MacFarlane's relativism (MacFarlane, 2011; 2014) takes the propositions expressed by epistemic modal sentences to be functions from (at least) < world, information state > pairs to truth-values. (I'll write these '<w,q>' – using 'q' as a variable for information states and leaving 'i' to be used later on when we've got *individuals* appearing in our indices.) So the extra parameter is an information state – represented as a set of worlds. He then goes on to say that the process by which utterance truth is determined is more complicated than on the standard Kaplanian picture. Recall how we portrayed the Kaplanian picture before:

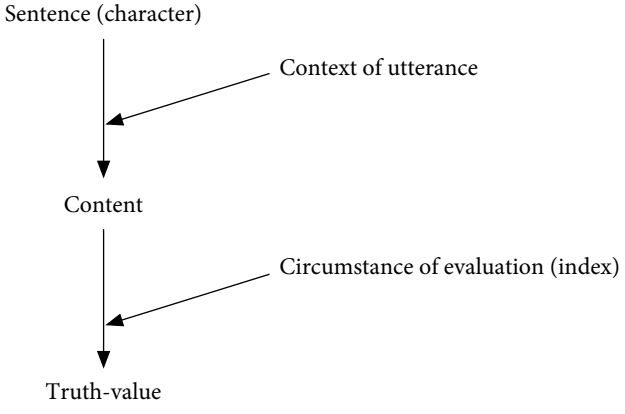

Figure 32.2

Really, this diagram leaves part of the story out. On the standard Kaplanian picture, not all indices are equal with respect to their role in the determination of truth-values for utterances, or for sentences in context. *Utterance* truth, and the accompanying notion of the truth of a sentence S in a context C, is sensitive only to the verdict that the content of S in C delivers about a *particular* index – the one that corresponds to the context C. (Depending on what parameters we've got in our indices, this is the index whose world is the world of C, whose speaker is the speaker of C, whose standards of precision are the standards in effect in C, etc.) If we want our diagram to reflect the full Kaplanian story about the determination of truth-values of sentences in context, we should write:

This addition allows our diagram to capture the way that, on the Kaplanian picture, the truth-value of a sentence in context is sensitive to context of utterance twice over – once as an input to character, and once as what we might call an *index-selector*. In particular, it indicates the special role that the context of utterance plays in the selection of the index that's relevant to the *sentence's* truth-value in the context of utterance, and so to the *utterance's* truth-value *simpliciter*.

Making this explicit allows us to clearly display the difference between a MacFarlanian relativist account and a standard Kaplanian account. On MacFarlane's sort of relativism, it's crucial that, when assessing an utterance of S in C for truth or falsity, the determination of which index gets fed in to the content of S in C in order to determine the truth-value of the particular utterance is sensitive, not just to the context of utterance, but also to the context of assessment. (If index-selection was only sensitive to the context of utterance, then we'd be unable to get any variation of utterance truth across assessors, no matter how complicated we made our indices. See MacFarlane, 2005; 2009.)

On MacFarlane's picture, which index is relevant to the determination of utterance truth is determined partly by the context of utterance, and partly by the context of assessment. For example, ignoring times and assuming we have just <w, q> indices, the relevant index for determining the truth of an utterance relative to an assessor is $<w_{CU}, q_{CA}>$ (where 'CU' names the context of utterance, and 'CA' the context of assessment).

The important difference here (see Figure 32.3), obviously, is that it's not the context of utterance alone that's responsible for selecting the index that's relevant to the assignment of truth-values to sentences in context, or to particular utterances. Index-selection, on this picture, is accomplished by the context of utterance and context of assessment together. As a result, this is a picture on which there's no such thing as the truth-value of a sentence in a context of utterance *simpliciter*, or of the truth-value of an utterance *simpliciter*. There's only the truth-value of a sentence relative to a *pair* of a context of utterance and a context of assessment, or of an utterance relative to a context of assessment. That's because it's only once we've got both a context of utterance and a context of assessment that we know which index to feed in to the content in order to get a truth-value. (On at least the first-pass version of MacFarlane's relativism about epistemic modals, *might:P* is true at <CU, CA> iff what is known to the assessor at CA is compatible with the truth of P at <CU, CA> .)

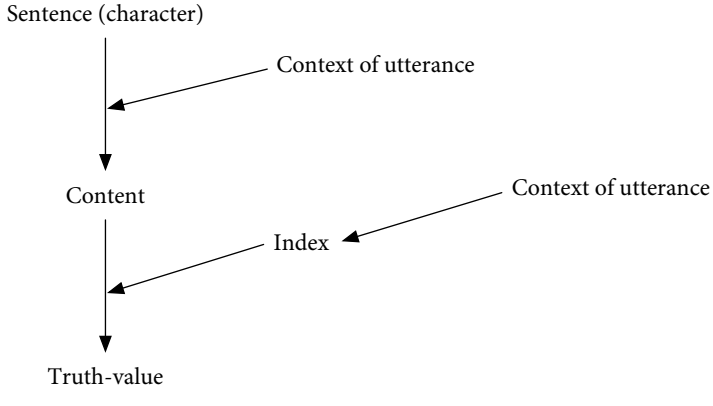

Figure 32.3

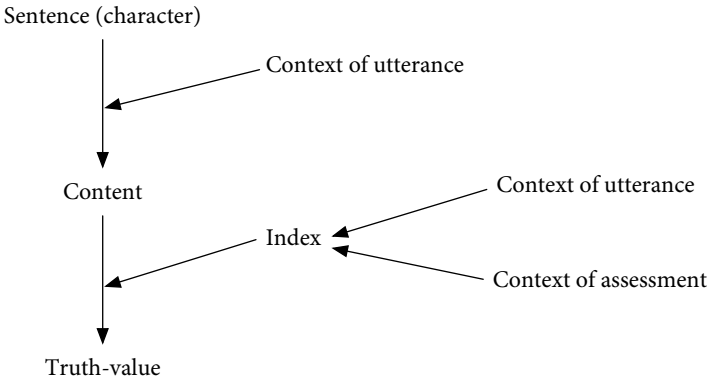

Figure 32.4

This allows for a different kind of variation in whose informational state is relevant than we find in contextualist theories. Here, the truth-values of epistemic modal claims are sensitive to the information available to the *assessor*. As a result, we can get the same utterance correctly assessed as true by one assessor, and correctly assessed as false by another.

Another relativist option is a theory that trades in *de se* linguistic content, as advocated by Tamina Stephenson (2007) and myself (Egan, Hawthorne, and Weatherson, 2005, Egan, 2007; 2010). Our views are different in detail, but for our purposes here I'll lump them together under the single heading of "*de se* relativism." On this kind of view, the parameter-adding is achieved by moving to a framework in which sentences in context have *de se* contents. (For more on the *de se*, see, for example, Lewis, 1979; Chisholm, 1981; Chierchia, 1989; Feit, 2008.) This is a picture of content on which the contents of sentences in context divide a space of possible *situations* or *predicaments*, rather than a space of worlds. Possible predicaments are standardly modeled with centered worlds, which we can think of as < world, time, individual > triples. (Peter Lasersohn's (2005; 2009) version of relativism is also in many ways similar, as is Max Kölbel's (2002; 2003; 2009), though their accounts are targeting other subject-matters. A third relativist option, which I will not discuss in detail for reasons of space, is Iris Einheuser's (2008) *factual relativism*.)

Possible predicaments (or centered worlds) differ from one another in many ways, including differing with respect to the evidential situation of the individual at the center. Epistemic modal sentences express centered-worlds propositions that are true of all and only those in a certain kind of epistemic situation. (For example, *might:P* is true at all and only those < world, time, individual > triples < w, t, i > such that the evidence within i's epistemic reach at t in w doesn't rule out P.)

Once we're given this account of the nature of the indices, we have the first component of a relativist story: we have contents that can take different truth-values relative to your predicament and to mine. We still need the second part of the story: an account of the role that the context of assessment plays in index-selection, such that it can happen that different indices are relevant to the assignment of a truth-value of an utterance when assessed by different individuals at different times. The simplest picture is this:

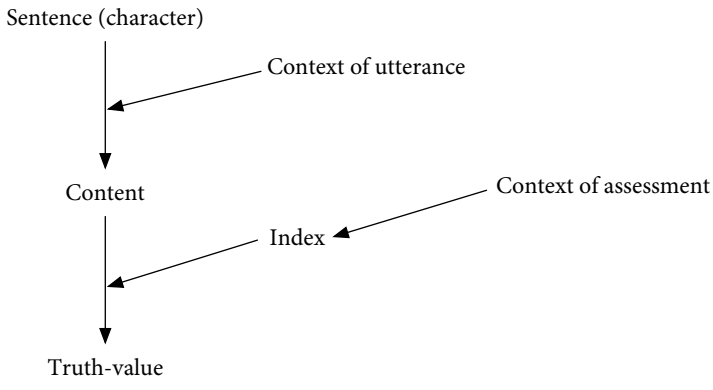

Figure 32.5

This is again a picture according to which the fundamental notions are not truth-in-a-context-of-utterance *simpliciter* for sentences, or of truth *simpliciter* for utterances. For sentences, the fundamental notion is truth relative to a < context of utterance, context of assessment > pair, where the context of utterance acts as input to character, and the context of assessment plays the index-selection role. For utterances, the fundamental notion is truth relative to a context of assessment.

This again makes the epistemic state of the assessor relevant to the truth and falsity of epistemic modal claims, in a way that it's not on the contextualist picture. And so it allows for variation in the truth-value of a single utterance relative to different assessors.

The above picture – on which the context of assessment always has sole responsibility for index-selection – is a natural one. But it's worth noting that it's not the only one available – this will be relevant later, when we're discussing some of the arguments for and against relativist theories.

One other thing that's worth noting briefly about the *de se* relativist view is that it can be stated in such a way that it's just an instance of the usual Kratzerian framework. The relativist needs to say that the relevant accessibility relations hold between centered worlds, rather than worlds, and they need to draw a distinction between "coarse grained" accessibility relations such that accessibility depends only on the *world* members of the < world, time, individual > triples (and so would be equally well modeled by accessibility relations between worlds), and those "finer grained" accessibility relations that are sensitive to other members of the triple. The proposal will then be that one of the distinctive features of *epistemic* uses of modal expressions is that the relevant accessibility relation is fine-grained, while other types of modality are governed by coarse-grained accessibility relations.

Notice that the kind of view just discussed is one that is both contextualist and relativist. The relevant accessibility relation is still fixed by context. But there's less diversity among epistemic accessibility relations contributed (at least in simple, unembedded environments) than standard contextualist views maintain.

5 Relativists' Arguments against Contextualism

Contextualist theories say that different utterances of the same sentence can take different truth-values, because they express different contents. Relativist theories say that there's more variation than this – that we can't accommodate all of the truth-value variation that we see in terms of variation, across contexts of use, in which contents are expressed.

There are two major families of arguments for this: First, what I will call *common-content* arguments, which aim to show that two utterances which we'd like to say differ in their truth-value must, after all, have the same content (and so that variation in truth-value can't be chalked up to variation in content). Second, what I'll call *single-utterance* arguments, which aim to show that particular, token utterances can take different truth-values relative to different assessors. We'll look at the common-content arguments first.

One family of argument for common content across occasions of utterance is based on *disquotational reporting*: If Fred says, "Bob might be in his office," it seems as if it's systematically okay for Fran to deliver disquotational indirect speech reports and (assuming Fred was being sincere) disquotational belief reports such as, "Fred said that Bob might be in his office" and "Fred believes that Bob might be in his office." This seems to be so regardless of what Fran's context is like – in particular, it's so regardless of whether Fred's and Fran's contexts are alike with respect to the features that will, given a contextualist account, plausibly be relevant to fixing the semantic value of "might." This isn't what you'd expect, at least at a first pass, given a contextualist account of "might."

Contextualist accounts seem to predict that "might" will take its semantic cues in the original utterance from *Fred's* context, and in the report from the *reporter's* context. If that were so, disquotational reports would run the same kind of risk of misreporting as do disquotational reports involving such paradigmatic indexicals as "I" and "here." If Fred says, "I am in New Brunswick," or "it's raining here," it *isn't* systematically okay for Fran to deliver disquotational reports. Reporting with "Fred said that I am in New Brunswick" is systematically bad, and "Fred believes that it's raining here" is only okay if Fred's and Fran's contexts of utterance are alike with respect to the semantic value they determine for "here."

In general, the problem is that Fred's utterance in C1 expresses the proposition *that Bob might$_{C1}$ be in his office*, while Fran's report in C2 expresses the proposition *that Fred said that Bob might$_{C2}$ be in his office*. Since C1 ≠ C2, it's very likely that "might" will express something different in the two contexts, and so it's very likely that Fran's report will be mistaken. (One natural possibility: Fran will misreport Fred as having said that it's compatible with what *Fran* knows that Bob is in his office.)

But disquotational reports are, in fact, completely safe. So, the relativist argument goes, there must not be a danger of "Bob might be in his office" having different semantic values in the context of utterance and the context of reporting. And so "Bob might be in his office" must have the same semantic value across the board. And so contextualism about "might" must be mistaken. And if contextualism about "might" isn't correct, then the best way to explain the variation that we see in the truth-values of different "might" claims is by saying that the stable content of "might" claims can take different truth-values relative to different contexts of assessment. (Versions of this argument occur in, for example, Kölbel, 2002, and Egan *et al.*, 2005.)

Another kind of disquotation-based argument for common content is based on disquotational attributions of agreement and disagreement. If Larry says, "Bob might be in his office," and Lisa says, "It's not the case that Bob might be in his office," Liz can report on this by saying, "Larry and Lisa disagree about whether Bob might be in his office." Similarly if Larry and Lisa both say, "Bob might be in his office," Liz can report on this by saying, "Larry and Lisa agree that Bob might be in his office."

These kinds of reports seem safe – their appropriateness doesn't seem to be hostage to the facts about what Larry's, Lisa's, or Liz's contexts are like. But we wouldn't – at least at first glance – *expect* these kinds of reports to be safe if contextualism about "might" were true.

For example, given a contextualist view of "might," there ought to be a danger that, since Larry was speaking in C1 and Lisa in C2, Larry said *that Bob might$_{C1}$ be in his office*, and Lisa said *that it's not the case that Bob might$_{C2}$ be in his office*. And these two claims, since they're (quite likely) about the epistemic situations of different persons or groups, needn't be in any conflict with each other. Worse, since "might" in Liz's report will get its semantic value from *Liz's* context, she's in danger of reporting Lisa and Larry as disagreeing about something that, quite likely, neither of them has any views about at all – for example, about whether it's compatible with what Liz knows that Bob is in his office.

Notice that the argument here isn't that, on a contextualist view, disquotational disagreement – or agreement – reports are *always* defective. The argument is that, in fact, the relevant kinds of disquotational reports are *always* okay, and contextualism predicts that they'll only be okay in certain narrowly constrained circumstances, in which the two parties' contexts are aligned with respect to the semantic value they determine for "might." Liz doesn't, in fact, have to verify that Lisa and Larry are in relevantly similar kinds of contexts before she can, with confidence, report them as disagreeing/agreeing. It's enough that she knows that they sincerely produced the relevant sentences. (Mark Richard (2004; 2009) makes these kinds of arguments in favor of a type of relativism in other domains, though he does not endorse relativism about epistemic modals.)

The arguments we've just canvassed are all arguments that the content of epistemic modal claims is stable across contexts of utterance, and so to the extent that we've got different intuitions about the truth-values of different utterances of a *might:P* claim, that must be because it's got the sort of content that can vary in truth-value at different points of evaluation within a world, rather than because it's expressing different contents in different contexts of use. Since the variation in truth-value across utterances isn't attributable to variation in *content*, it must be that the *same* content is taking different truth-values at the different indices relevant to assessment of the utterances.

This leads to a worry about all of these arguments: These look like better arguments for the sort of view MacFarlane (2009) describes as "nonindexical contextualism" than for any of the views that have been advocated under the heading of *relativism* about epistemic modals. They're arguments that different utterances of the same epistemic modal sentence (within a world) can take different truth-values, without differing in content. But they're not arguments that a *single utterance* of an epistemic modal sentence can take different truth-values relative to different assessors. And so they're not (at least not without further premises) arguments that the *assessor's* epistemic state ever needs to be relevant to determining the truth or falsity of an epistemic modal claim.

They're arguments, that is, that we need contents that take truth-values relative to something more than a world – since we've got the same contents being expressed by our various speakers in the examples, all of whom are worldmates, so that each of their contexts will supply the same world to the circumstance of evaluation that's relevant to the determination of utterance truth. But they're not arguments (at least, not without further premises) that particular utterances don't get their truth-values once and for all, or that we need to allow a role for contexts of assessment in the assignment of truth-values to sentences in context.

These sorts of common-content arguments are, in fact, most naturally understood as arguments that utterances with the same content can get different "once and for all" truth-values, *not* as arguments that we need to relativize utterance truth to contexts of assessment.

(For more on non-indexical contextualism, see MacFarlane, 2009. For extensive discussion and criticism of these sorts of arguments for the view that propositional truth is relative to more than a world, see Cappelen and Hawthorne, 2009.)

One argument, which is an elaboration of the disagreement argument above, *does* seem to support (if it's successful) not just stability of content, but also a role for context of assessment in the determination of truth-values for utterances. This is the argument from *faultless disagreement*.

There are two key moving parts of the argument from faultless disagreement: First, there's an imposition of a requirement that the relevant cases be classified by the correct theory as cases of *disagreement*. In the simplest arguments from faultless disagreement, this requirement is understood as a requirement that A's utterance semantically expresses the negation of B's utterance.

Second, there's a requirement of *faultlessness*. Both have to be getting it right, "from their own perspective." This isn't quite enough, however, as we've just seen that this by itself doesn't motivate a relativism of a kind that allows contexts of assessment to play a role in the determination of utterance truth. To accommodate this, all we need is a standard contextualist view (or a non-indexical contextualist view) that makes both A's and B's utterances come out to be true (true once-and-for-all).

But if we add a further requirement – we could call it a requirement of *strong faultless disagreement* – then we really do have an argument for a kind of relativism that allows utterance truth to be sensitive to context of assessment. To motivate this sort of relativism, we need to impose a requirement, not just that A is correct to regard his own utterance as true, but also that A is correct to regard B's utterance as *false*. (And *vice versa* for B.) This really does force us into a full-bloodedly relativist view, because then we have a pair of particular utterances – A's and B's – that need to take one truth-value for A, and the other for B (rather than just a pair of utterances that need to take different once-and-for-all truth-values, despite having the same content).

(This sort of argument features prominently in relativist arguments on other topics, but less in arguments for relativism about epistemic modals. For some applications, see Brogaard, 2008a; 2008b; Egan, 2010; Kölbel, 2002; 2009; Lasersohn, 2005; 2009; MacFarlane, 2007; 2014; Stephenson, 2007. For some opposition, see Sundell, 2009; von Fintel and Gillies, 2008; Dowell, 2012.)

This sort of argument from strong faultless disagreement is a member of a family of arguments meant to show that particular token utterances can be true relative to one assessor and false relative to another (within a world). That is, they're meant to show that utterances don't get truth-values once and for all, but only relative to a context of assessment. The argument from faultless disagreement bears a lot of the weight in discussions of relativism about other domains (in particular, about personal taste), but other members of the same family of arguments have standardly borne most of the weight in the case of epistemic modals.

One such argument (prominent in MacFarlane, 2011; 2014) is based on *retraction* phenomena. There's a common conversational phenomenon of criticism and correction, in which one party to the conversation takes another to task for some previous utterance. (I say, "The cat is on the mat." You say, "Nuh uh, the cat is not on the mat.") Abstracting away from a lot of detail, the standard responses to such criticism fall into two broad categories: *concession/retraction responses*, and *sticking to one's guns*.

Attempts at a certain sort of criticism and correction, which target utterances featuring context-sensitive vocabulary, after a relevant change of context has occurred in between the

original utterance and the challenge, often evoke a distinctive kind of sticking-to-one's-guns: an *impatience/insistence* response, marked by such replies as, "oh, come on," "you know that's not what I meant," and "don't be a jerk."

For example:

The Drive

Dave: "It's hilly here"
(They drive along, out into the plains, changing the contextual features relevant to determining semantic value of "here.")
Tim: "Nuh uh. It's not hilly here at all."
Dave: "Oh, come on. You know that's not what I meant. Don't be a jerk."

Note that the alternative concessive/retracting response from Dave sounds weird and inappropriate here – it would be bizarre for Dave to reply to Tim's challenge with any of the kinds of replies that mark this sort of response (such as, for example, "oh, I guess I was wrong," "I take it back," "my bad," or "okay, scratch that, then"). A similar pattern (I'll say a bit more about just what the pattern is in a minute) seems to hold for context-sensitive vocabulary in general. It's easy to construct parallel examples for "tall," "nearby," and so on.

What's happened here is that, between the utterance and the challenge, there's been a shift in the relevant features of the conversational context. Prior to the shift, at the time of the original utterance, the context was one in which assertions of "it's hilly here" would be true. After the shift, the context has changed in such a way that an assertion of "it's hilly here" made in the new, post-change context would be false. More generally: the context has changed in such a way that, while the speaker ought to have taken himself to be in a position to truly assert what he did in the original context, the speaker ought no longer take himself to be in a position to truly assert the same sentence in the new, post-change context. Let's call such a change in the conversational context an *undermining* context change, since such a change undermines the speaker's ability to felicitously re-assert the same sentence. (The above is my best effort to state the phenomenon in terms that are neutral between contextualism and relativism. I fear that I may not quite have succeeded, but I hope I have done well enough to allow you to identify the phenomenon.)

With epistemic modals, on the other hand, we see a different pattern of appropriate reactions to challenges after undermining context changes:

Jane Emerges

Jim: "Bob might be in his office."
(Jane, previously not a participant in the conversation, introduces herself into the conversation, bearing a photograph of Bob in Amsterdam, just posted to Facebook seconds ago, changing the contextual features relevant to fixing the semantic value of "might.")
Jane: "Nuh uh. There's no way Bob is in his office – see, here's a picture of him going into a bar in Amsterdam just seconds ago."
Jim "Oops, my bad – I take it back."

Note that the alternative, impatience/insistence response seems out of place here. It would be off for Jim to respond to Jane's challenge by saying, for example, "oh, come on – you know that's not what I meant."

Retraction arguments against contextualism (and in favor of relativism) about epistemic modals are based on this pattern of response to challenges and criticisms after undermining context changes, which don't look like the ones that a contextualist theory would predict.

The most interesting use of these examples, for our purposes, is as an argument that a single, dated utterance can get different truth-values relative to different contexts of assessment: Assessed from its original context of utterance, Jim's claim is true. Assessed from the post-shift context of assessment, the very same utterance is false. That's why the speaker *retracts*, rather than just refraining from uttering the same sentence in the new, changed context.

The challenge to the contextualist is to explain the retraction phenomena while insisting that the initial utterance retains the same truth-value relative both to the original context of utterance and the later context of retraction. The relativist argues that this is going to be impossible to do.

If the contextualist says that the original utterance was (and remains) *true*, it's difficult to explain why the speaker retracts in the face of the later challenge. If the contextualist says that the original utterance was (and remains) *false*, it looks as if she'll have to say that that's because Jane's information was relevant all along. And this, according to the relativist, is going to make the truth-conditions for "might" claims too demanding. Once we allow Jane to be (and to have been all along) a member of the group whose evidence makes a difference to the truth of Jim's claim, it's hard to identify a principled place to stop short of *everybody who ever thinks about the utterance* being in the relevant group. And if that's so, "might" claims are going to look incredibly risky, and we'll barely ever be in a position to felicitously assert them, since it will be so easy for them to be false.

Responses to this sort of argument from defenders of contextualism fall into two categories: challenges to the data, and attempts to accommodate the phenomenon within a contextualist theory. (Often, these moves complement each other – the contextualist offers a more sophisticated theory that accommodates a lot of the troublemaking phenomena, and then challenges the data to argue that the remaining un-accommodated phenomena aren't genuine, or aren't genuinely problematic.)

One compelling response of the data-challenging type is to point out that the tendency to retract isn't as universal as the initial versions of the relativist argument suggest. We don't *always* get retraction in the face of challenges after an undermining context change. We sometimes get insistence and impatience. Here is a case from von Fintel and Gillies (2008):

The Keys

Alex: The keys might be in the drawer.
Billy: (Looks in the drawer, agitated.) They're not. Why did you say that?
Alex: Look, I didn't say they *were* in the drawer. I said they *might* be there – and they might have been. Sheesh. (von Fintel and Gillies, 2008, p. 81)

Alex's response seems completely appropriate. He should, in this case, dig in his heels, refuse to retract, and insist on the correctness of his past "might" claim. So it looks as if the phenomena here aren't as the standard relativist arguments portray them – at least, they're not as the simple versions of the relativist arguments portray them. There are two ways to use this against the relativist.

One use of insistence phenomena is *defensive*: since the data aren't as the relativist described them, the arguments from retraction phenomena fail, and the world is still safe for contextualism after all. While it certainly does seem to be true that the data aren't as simple as the standard relativist arguments make them out to be, it's not clear how successful this reply is. Plausible versions of this response will still leave us with *some* cases of retraction after what looks like a relevant context change (in particular, after the introduction of new participants to the conversation). These retractions will still need explaining, and they aren't predicted by at least the first sorts of contextualist theories that spring to mind. So this can't be a *complete* defense – there's also a need for an elaboration on the contextualist theory that allows it to accommodate the remaining cases of genuine retraction. (One such theory is offered by von Fintel and Gillies, 2011.)

Another use of insistence phenomena is *offensive*: the insistence data are actually quite uncomfortable for the relativist. Relativist theories seem to predict that assessors' truth-value assessments will *always* be based on whether the utterance under evaluation is true relative to their own present context of assessment (or relative to the pair of the context of utterance and their own present context of assessment). They predict, therefore, that we'll *never* see the kinds of insistence on past correctness that we see in *The Keys*.

The relativist needs to either explain these away or provide a story that accounts for them. One way to offer such an account is to follow Peter Lasersohn's (2005; 2009) lead, and allow for two different sorts of truth-value attributions: one that tracks truth relative to the assessor's present context, and one that tracks truth relative to the speaker's context of utterance. In the cases of retraction, what's at issue is whether original utterance is true in the conversationalists' present contexts of assessment. Correctly recognizing that it's false relative to his own present context of assessment, the speaker retracts. In the cases of insistence, what's at issue is whether the original utterance was true in the original context of utterance. Correctly recognizing that it is, the speaker insists.

Relativists of both the *de se* and MacFarlanian types have the resources available to make this distinction. (Though in MacFarlane's framework it will be phrased slightly differently – as the distinction between truth at the pair $<C_U, C_A>$ and truth at the pair $<C_U, C_U>$ – and MacFarlane himself seems not inclined to adopt it.) Both also face the challenge of explaining, in a way that's not *ad hoc*, just why the one kind of evaluation is relevant in the retraction-generating conversations, and the other kind is relevant in the insistence-generating conversations.

Another sort of argument for variations in the truth-value of particular utterances is what are often known as *eavesdropper* arguments, based on the assessments of utterances by third parties who are not participants in the conversation in which the utterance takes place. Unlike what we find with standard context-sensitive expressions, and unlike what one would expect from a context-sensitive expression, evaluators who are not parties to the conversation in which an utterance occurs systematically base their assessments of utterances of epistemic modal claims on (their views about) their *own* evidential state, not on (their views about) the evidential state of the speaker, speaker's group, and so on.

For example, here is a contrasting pair of cases from MacFarlane (2011):

George and Sally

First case: You overhear George and Sally talking in the coffee line. Sally says, "I don't know anything that would rule out Joe's being in Boston right now" (or

perhaps, more colloquially, "For all I know, Joe's in Boston"). You think to yourself: *I* know that Joe isn't in Boston, because I just saw him an hour ago here in Berkeley. *Question:* Did Sally speak falsely?

Second case: Scene as before. Sally says, "Joe might be in Boston right now." You think to yourself: Joe can't be in Boston; I just saw him an hour ago here in Berkeley. *Question:* Did Sally speak falsely?

The hope is that you will have answered "no" to the first question and "yes" to the second. And this does indeed seem to be the reaction most people have. This example, as MacFarlane deploys it, is meant to do a number of things: It's supposed to identify an important difference between, for example, "Joe might be in Boston" and, for example, "As far as I know, Joe is in Boston," and thereby head off any equivalence claims that we might otherwise have been tempted to make. More importantly, it's also supposed to show that our assessments of the truth-values of other people's "might" claims, even those that take place in conversations that we're not parties to, are based on what we think about *our own* epistemic state, not on what we think about the epistemic state of the speaker, or the people who are party to the conversation in which the utterance takes place.

Here is another way of getting at the same phenomenon: Moore (1962) notes that one of the markers of the fact that "It's possible that Hitler is now dead" and "Hitler may be dead" are *epistemic* possibility claims is that one can use "I know that he's not" to deny them. This is an instance of a striking general feature of epistemic possibility claims, which is illustrated above, and also by Hawthorne's inspirational footnote: *anybody* can use first-person knowledge claims to deny them – not just addressees, and not just participants in the conversation in the course of which the claim is made.

The relativist argument here is that contextualists can't give an adequate explanation of this fact, while a relativist view is ideally suited to explain it. Contextualism, the relativist charges, predicts that competent extra-conversational assessors will defer, in their assessments of utterances for truth and falsity, to the context of utterance for content-determination and index-selection. So they shouldn't, in general, take their own epistemic state to be relevant, any more than they should take their own *location* to be relevant when they're assessing occurrences of "here" claims in conversations that they're not participants in.

One candidate contextualist reply here is to say the extra-conversational evaluator's epistemic state really *was* relevant all along, and so the utterance is just plain false. The trouble with this is that it's difficult to tell such a story without making the truth-conditions for epistemic "might" claims excessively demanding.

We don't, as a matter of fact, need to rule out the presence of better-informed lurkers in the closet in order to take ourselves to be in a good position to make "might" claims. And even if we *strongly suspect* lurkers – even if we're *certain* there's a lurker – we still don't take our "might" claims to be hostage to the lurker's knowledge. An example to make this clear: Tony Soprano can felicitously say to Paulie, "be careful, the Feds might have a guy outside your house," even if they're sure that there's an FBI agent listening in who knows for sure whether there's a guy outside Paulie's house. This is so even if Tony is pretty confident that there *isn't* a Fed outside Paulie's house, and that the eavesdropper knows this. And it's so even if he thinks the eavesdropper is hiding in the closet rather than listening in on a wiretap. (Tony could also say, "there might be a guy outside the house, and there might not. But it's best to be careful." At least one conjunct of this is sure to be false if the eavesdropper's knowledge is relevant.)

The relativist proposes to explain these phenomena by offering a semantic theory according to which a single, dated utterance of an epistemic modal claim can take different truth-values relative to different assessors, so that it's true for (e.g.) the speaker, and false for the extra-conversational assessor.

Here too, there are two types of reply available to the contextualist: they can challenge the data, or they can offer a way for a contextualist theory to accommodate the phenomena. (There is also the mixed strategy, of challenging the data to cut down the range of phenomena to be accommodated, and then telling a story that accommodates the remainder.)

Many of the standard presentations of eavesdropper arguments (see, for example, Egan, Hawthorne, and Weatherson, 2005; Egan, 2007) rely on intuitions about assessors' utterances of "that's true" or "that's false" in response to overheard epistemic modal claims. One concern about such intuitions is that just what they show depends on how some difficult issues about propositional anaphora wind up playing out. In particular, one way to resist the relevance of those intuitions is to offer alternative hypotheses about the reference of "that" in the relevant utterances, such that what the assessor is delivering an assessment of isn't the original utterance, or the proposition it expressed. (See, for example, von Fintel and Gillies, 2008, for some such replies.)

There are a couple of strategies available to the relativist in order to counter this reply. One is to tailor the responses in the examples in order to make the anaphora unambiguous (narrowing in, for example, on *Bob might be in his office* rather than the prejacent *Bob is in his office* as the target of assessment by noting that it seems in order for the evaluator to say, for example, "that's false, there's no way Bob is in his office," or "that's false, it's impossible that Bob is in his office"). Another alternative is to restate the argument in anaphora-free terms, as I have followed MacFarlane in doing here.

Besides challenging the relativist's claims about the data regarding extra-conversational assessments, another possible strategy is to adjust the contextualist theory in order to accommodate them. One option here is to tighten up the truth-conditions for epistemic "might" claims, so that the speakers *are* speaking falsely, but blamelessly. The intra-conversational assessors are making the same sort of blameless mistake as the speaker, and the extra-conversational assessors are just getting their truth-value assessments right. The most natural way to do this is to say that eavesdroppers are, in general, to be included in the relevant group whose epistemic state makes a difference to the truth or falsity of epistemic modal claims. This strategy is subject to the same kind of concern as the analogous response to retraction arguments above: it's very hard to do this without making the truth-conditions for epistemic modal sentences (a) so demanding that we're basically never in a position to assert them, and (b) demanding in ways that make bad predictions about when we should take ourselves to be in a position to assert them. (Though see von Fintel and Gillies, 2011, for a contextualist strategy that seeks to avoid this problem.)

There is, obviously, much more to say about all of this. But I hope that this section has succeeded in displaying at least the standard motivations for relativism about epistemic modals, and the first step or two of the ensuing debates.

Conclusion

I've tried in the preceding to lay out, in broad strokes, the candidate relativist views about epistemic modals, and the contextualist orthodoxy that they're seeking to replace. I've also tried to lay out, in similarly broad strokes, the main arguments relativists offer for

their views, and the first few steps of the ensuing debate between the relativists and the anti-relativists about whether or not those arguments succeed. While I've looked at some of the anti-relativists' responses to the relativists' positive arguments, one thing that I have not done, due to limitations of space, is survey the various positive arguments against relativism that its opponents offer. I will close, then, with some suggestions, for those who are interested, of points of entry into that area of the literature:

For some positive arguments against (or at least doubts and concerns about) relativism in general, and not specifically about epistemic modals, see, for example, Wright (2008), Cappelen and Hawthorne (2009), García-Carpintero (2008), Evans (1985), and von Fintel and Gillies (2008).

For some arguments against relativism about epistemic modals in particular, see, for example, Dietz (2008), Dowell (2010), von Fintel and Gillies (2011), Schaffer (2011), Yalcin (2007; 2011), and Swanson (2011).

Internalism and Externalism

JUSSI HAUKIOJA

1 Introduction: Internal Duplicates and Supervenience

Suppose that somewhere – maybe on another planet, maybe in another possible world – an exact molecule-for-molecule replica of you exists, uttering the same sentences, in languages that are syntactically and phonologically identical to the ones you speak. Will the expressions uttered by your replica have the same meanings as the expressions you utter? Many people feel, at least pre-theoretically, that the answer is, obviously, "yes" – this is the semantic *internalist* answer. Yet, most philosophers of language today would say that the meanings of at least some expressions used by you and your replica may differ, and in so doing commit themselves to semantic *externalism*.

Semantic externalism and internalism can be characterized in various different ways. The central and distinctive externalist claim is, roughly, that the meanings of at least some linguistic expressions are not wholly determined by, or supervenient on, the intrinsic features of the speaker. In this chapter, I will understand internalism and externalism as supervenience theses, or rejections thereof. Semantic internalism is, then, the view that the propositional contents of the sentences uttered by a speaker supervene on the intrinsic features of the speaker. Semantic externalism, on the other hand, is the negation of semantic internalism: according to externalism, propositional content *fails* to supervene on the intrinsic features of the speaker.[1]

These characterizations are, of course, at most as precise as the expressions "propositional content" and "intrinsic features." Moreover, even when it has been made clear exactly how these expressions are here to be understood, the characterizations leave open a wide range of different views regarding which features of propositional content supervene, or fail to supervene, on the intrinsic features of a speaker, as well as which external features semantic externalism would claim have to be added to the speaker's intrinsic properties, in order to find a sufficient supervenience base for propositional content.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

One of my main aims in this chapter is to clarify what the main options for externalist theories are, and what sorts of arguments are relevant for a given kind of view.

Formulating the view explicitly in terms of supervenience helpfully illustrates the role of *internal duplicates* in arguments for externalism. Semantic externalism is typically *not* argued for by deriving it from other general principles or assumptions. Rather, the evidence typically cited as persuasive for externalism consists, at least primarily, of thought experiments featuring precisely the kinds of internal duplicates mentioned above. In such thought experiments – the most famous being, of course, Putnam's Twin Earth – we imagine internal duplicates that are situated in different environments, speaking languages that are syntactically and phonologically identical. The externalist appeals to an intuition, or judgment, according to which the semantic properties of the expression tokens produced by the two duplicates are *not* identical. If the externalist is right in this, some kind of semantic externalism follows: some semantic feature of at least some linguistic expressions is dependent on external features, and not supervenient on the intrinsic properties of the speaker.

Understood in this way, semantic externalism and internalism are claims in *foundational* rather than *descriptive* semantics.[2] That is, they are views regarding the determination basis of the meanings of linguistic expressions, not views concerning what the meanings of such expressions are. Unfortunately, in discussions of externalism and internalism this is not always carefully kept in mind, probably partly because the classic arguments for externalism were also arguments against semantic *descriptivism*, which in turn can be construed both as a thesis in foundational semantics *and* as a thesis in descriptive semantics. It is important, however, to note that the issues are distinct. For example, even though a descriptivist theory in descriptive semantics is typically combined with a semantic internalist view in foundational semantics, there is no logical inevitability here: one could consistently be a descriptivist about meaning but hold that the descriptive contents of our terms are partly externally determined (perhaps by committing to a social externalist view, cf. §4 below).

As noted above, semantic internalism can appear quite attractive, at least pre-theoretically. Indeed, internalism seems to have been the default position in philosophy of language until the 1970s. After the famous arguments by Kripke, Putnam, Burge, and others, however, the situation changed quite rapidly, and today most philosophers of language would subscribe to at least some kind of semantic externalist thesis. The main focus of the discussions has been on finding out exactly what kind of an externalist thesis (if any) the externalist arguments manage to justify. This is also very much visible in this chapter – my focus will be on different arguments for various kinds of externalist theses, rather than on arguments for internalism.

I have above characterized semantic externalism and internalism as general claims: internalism holds that propositional content is *always* supervenient on intrinsic properties – externalism, as the negation of internalism, holds that the corresponding expressions (i.e. expressions which are phonetically or orthographically identical) used by duplicates may *at least in some cases* differ in *some* of their semantic properties. But this general externalist claim is of course consistent with holding that the semantic properties of *some* expressions *are* supervenient on the intrinsic properties of the speaker. Thus, it is often useful to discuss externalist views about a *class* of expressions. One might, for example, be an externalist about natural kind terms (and thereby qualify as a semantic externalist in the general sense), but be an internalist about, say, artifact terms. I will use the terminology in both senses below: the context will, I trust, make the interpretation sufficiently clear.

I will proceed as follows. In the next section I will review the central thought experiments often considered as giving strong support to externalist theses, paying close attention to how internal duplicates figure in the experiments. In §3 I will distinguish between different semantic externalist claims, based on *which* semantic feature is being claimed to be at least partly dependent on features external to the speaker. In §4 different externalist claims are distinguished based on another, independent dimension: based on how the supervenience base for semantic properties should be widened, by taking in features of the external environment. Finally, in §5 I will look at methodological and meta-philosophical aspects of the internalism/externalism debate, and discuss what makes a particular kind of semantic externalist claim true, when it is true. Relatedly, I will look at whether and why thought experimentation should be thought of as a fruitful way of arguing for and against semantic externalism. For the most part, my aims in this chapter are clarificatory: to distinguish between different kinds of externalist claims and to clarify what kinds of argument are relevant in arguing for and against them. However, in my discussion of the methodological and meta-philosophical issues in §5 I will explore the consequences of adopting a *dispositionalist* and *meta-internalist* perspective, developed in recent work.

2 Origins of Semantic Externalism

The roots of semantic externalism are found in the works of Saul Kripke (especially Kripke, 1980) and Hilary Putnam (especially Putnam, 1975) – indeed, the label "Kripke–Putnam externalism" is sometimes used. Despite the many points of convergence, however, Kripke and Putnam developed their views independently of each other in the 1960s (for a recent account of the development, see Putnam, 2013). For contemporary externalism, the slightly later works by Tyler Burge (especially Burge, 1979) are just as central. In this section I will outline the central arguments for externalism by Kripke, Putnam, and Burge. I am going to be purposefully vague when it comes to different formulations of externalism – these will be clarified in some detail in §§3 and 4.

Unlike Putnam and Burge, Kripke does not in *Naming and Necessity* (Kripke, 1980) argue explicitly in terms of duplicates. His main aim is to refute *descriptivist* theories of meaning (or, rather, "naming") for proper names and natural kind terms; the role of internal versus external factors is not highlighted in Kripke's discussion. However, it is quite clear that the alternative causal-historical picture he sketches is externalist: the determination basis of meaning for these expressions involves external factors such as naming ceremonies and episodes of reference borrowing that may have taken place before the relevant speaker was even born. Moreover, in his discussion both of proper names and of natural kind terms Kripke argues that one might be in an *epistemic situation* that is *qualitatively identical* to the actual one, but situated in a different environment, and be referring to different entities or properties with one's proper names and natural kind terms (Kripke, 1980, pp. 102–105, 150–152). This is very much in the spirit of semantic externalism, formulated as a failure-of-supervenience thesis (although strictly speaking it leaves open the possibility that the semantic properties of proper names and natural kind terms are determined by intrinsic properties of speakers that are irrelevant to the qualitative aspects of the speakers' epistemic situations).

We can safely say that Putnam's Twin Earth thought experiment is the most famous argument for semantic externalism (although Putnam does not use the term "semantic externalism"

in "The meaning of 'meaning'"). Here, internal duplicates play an absolutely central role.[3] Putnam's main aim in the paper is to show that the following two traditional assumptions cannot both be true (Putnam, 1975, p. 219): (1) knowing the meaning of a term is just a matter of being in a certain (narrow) psychological state, and (2) the meaning of a term determines its extension.

To show that at least one of these assumptions has to be abandoned, Putnam presents his famous thought experiment (Putnam, 1975, pp. 223–224). Planet Twin Earth is very much like our Earth: we may even imagine that each of us has an internal duplicate on Twin Earth, sharing all our internal properties, our behavioral history, and so on. However, the liquid called "water" on Twin Earth does not consist of H_20, but of XYZ, where "XYZ" is an abbreviation for a complex chemical formula; XYZ is "indistinguishable from water at normal temperatures and pressures." Putnam goes on to imagine that a spaceship from Earth visits Twin Earth. At first the Earthlings will, according to Putnam, assume that "water" has the same meaning on Earth and on Twin Earth. When apprised of the chemistry, however, the Earthian spaceship will "report somewhat as follows: 'On Twin Earth the word "water" means *XYZ*'"[4] (Putnam, 1975, p. 223).

Next, Putnam imagines that in the year 1750, before chemistry had developed on either planet, a pair of intrinsic duplicates existed: Oscar on Earth and Twin Oscar on Twin Earth.[5] No speakers on either Earth or Twin Earth were aware of the molecular structures of the watery substances in their environment. Nonetheless,

> […] the extension of the term "water" was just as much H_2O on Earth in 1750 as in 1950; and the extension of "water" was just as much XYZ on Twin Earth in 1750 as in 1950. [Oscar and Twin Oscar] understood the term "water" differently in 1750 *although they were in the same psychological state* […] Thus the extension of the term "water" (and, in fact, its 'meaning' in the intuitive preanalytical usage of that term) is *not* a function of the psychological state of the speaker by itself. (Putnam, 1975, p. 224, emphasis in the original)

If Putnam is right about the extensions of tokens of "water" on Earth and Twin Earth, the failure of supervenience on internal features is evident – Twin Earth is tailor-made to establish that such supervenience fails.[6]

In the same paper, Putnam also introduces slightly different kinds of examples to illustrate what he calls the "division of linguistic labour" (Putnam, 1975, pp. 226–227). For example, he tells us that he cannot distinguish between elm trees and beech trees. Nonetheless, according to Putnam, "we still say that the extension of 'elm' in my idiolect is the same as the extension of 'elm' in anyone else's, viz., the set of all elm trees, and that the set of all beech trees is the extension of 'beech' in *both* of our idiolects." This is because Putnam, and many other speakers, are *deferring* to *experts* who belong to the same linguistic community. Again, Putnam claims that a Twin Earth-style experiment can be constructed: suppose that on Twin Earth, the extensions of "elm" and "beech" are switched. This difference entails that the *experts* on the two planets cannot be each other's internal duplicates, but since Putnam and Twin Putnam are both unable to tell elm trees and beech trees apart, there may be no internal difference between them. Again, if we agree with Putnam about the extensions of "elm" and "beech," as used by him and his twin, the failure of supervenience is apparent.

Putnam's focus in "The meaning of 'meaning,'" and other papers putting forward externalist views, was solely on language. It was quickly noted, however, that if Putnam's

arguments work for natural kind *terms*, then a similar argument looks overwhelmingly plausible for natural kind *concepts*, establishing a similar externalist conclusion about them, and the intentional mental states in which they figure (McGinn, 1977). Soon thereafter, Tyler Burge argued that a similar result holds far more widely than merely for names and natural kind terms and concepts.

In his most famous thought example, Burge (1979, pp. 77–79) introduces a subject – let us call him Bert – reporting to his doctor on his ailments. Bert believes (correctly) that he has arthritis in his wrists and fingers, and has a number of other true beliefs about his disease. In addition, however, he falsely believes that his arthritis has spread to his thigh – he mistakenly believes that arthritis can affect both joints and muscles, whereas in reality arthritis is specifically an inflammation of joints. Next, Burge has us imagine a counterfactual situation where a subject – let us call him Twin Bert – "proceeds from birth through the same course of physical events that [Bert] actually does, right to and including the time at which he reports his fear to his doctor" (p. 77). Twin Bert and Bert are internal duplicates, but in Twin Bert's linguistic community, the term "arthritis" has wider application: "physicians, lexicographers, and informed laymen apply 'arthritis' not only to arthritis but to various other rheumatoid ailments" (p. 78). Let us suppose that on this counterfactual usage, Bert's muscle ailment *would* be included in the extension of "arthritis." According to Burge, when Bert says, "I have arthritis in my thigh," he is saying something false (indeed, necessarily false), while Twin Bert, uttering the same sounds, is saying something true – despite the fact that the two speakers are internal duplicates. Again, if we agree with Burge on this, semantic externalism in the sense under discussion follows directly.

Burge's main focus was on contents of intentional mental states, on our attributions of contentful mental states, and on the phenomenon of incomplete understanding. However, his thought experiment is at least equally effective as an argument for semantic externalism. And, as Burge points out, his thought experiment does not depend on any features specific to the term "arthritis," or to names of diseases in general: instead of "arthritis," we "could have used an artifact term, an ordinary natural kind word, a color adjective, a social role term, a term for a historical style, an abstract noun, an action verb, a physical movement verb, or any of various other sorts of words" (Burge, 1979, p. 79). If Burge is right, a similar argument can establish some form of semantic externalism about most, maybe even all, linguistic expressions.

3 Which Semantic Feature Is Externally Determined?

A noteworthy fact about the arguments mentioned in the previous section is that they concern first and foremost *reference* and *extension*. The driving force behind the thought experiments is the conviction that syntactically and phonologically identical utterances made by internal duplicates can have different *truth-conditions*. Most people who are impressed by the Twin Earth thought experiment take the experiment (and others like it) to establish a claim about *meaning*: not only are the *extensions* of some linguistic expressions partly determined by features external to the speaker (in a sense to be made clear below), so is the cognitive content of said expressions, or, the contents that speakers communicate when using them. Let us call this view *externalism about meaning*. Of course, if we assume (with Putnam) that meaning determines extension, then an argument for the claim that extensions are externally determined will also directly be an argument for externalism about

meaning. In practice, things are more complicated, as we will see. Many theorists have thought it possible to accept Putnam's judgments concerning reference in the Twin Earth example, but try to accommodate them in a theory of meaning that is in some central respects internalist.

Nonetheless, to accept the Putnamean judgments (or 'intuitions') about Twin Earth is already to accept that *some* central semantic features do not supervene on the intrinsic properties of the speaker. We need, then, a formulation of the minimal view that is directly supported by Twin Earth-style thought experiments – a view that one is committed to merely by virtue of agreeing with Putnam that Oscar's tokens of "water" refer to H_2O, but not XYZ, both on Earth and on Twin Earth, while Twin Oscar's tokens of a phonetically identical term refer to XYZ, but not H_2O, on both planets. Let us call this view *externalism about extension*.

Externalism about extension is the claim that the referents or extensions (across possible worlds[7]) of corresponding expressions, used by internal duplicates, may differ. More explicitly, according to *in*ternalism about extension, if speakers A and B are internal duplicates, then their phonetically and syntactically identical expression tokens e_A and e_B have identical extensions in all possible worlds. Externalism about extension denies this.

While most philosophers (post-Putnam) are externalists in this sense, internalism about extension has also had its defenders. According to the *common concept strategy* (e.g., Mellor, 1977; Crane, 1991; Segal, 2000), Oscar's and Twin Oscar's tokens of "water" have the same meaning and the same extension across possible worlds, applying both to H_2O and to XYZ. The problem with the common concept strategy is that it appears to fly in the face of semantic facts: externalists take it to be simply *obvious* that the extension of Oscar's tokens of "water" includes H_2O and excludes XYZ, and vice versa for Twin Oscar. (Not everyone will agree that this is obvious. I will return to this question below, in §5.)

Some externalists about extension want to insist that meaning and content are nonetheless, in some respect, internal – or at least that there is a component of content, narrow content, that is supervenient on the intrinsic properties of speakers. We should keep in mind that Putnam already acknowledged that there are two "plausible routes" to take, as a reaction to the Twin Earth thought experiment (1975, p. 245) – one could reject either of the two traditional assumptions that his argument, if successful, shows to be incompatible. His own route – rejecting the assumption that understanding a term is a matter of being in a particular narrow psychological state – is not dictated by the thought experiment. One might, alternatively, hold on to this assumption and reject the assumption that meaning determines extension. Putnam (1975, p. 246) feels that his route better respects our established ways of talking about sameness and difference of meaning, but this seems to be partly a matter of terminological preference.

However, not all hinges simply on terminological choice: substantial claims concerning knowledge and understanding, of what is communicated, and so on, can also come into play. For example, proponents of causal descriptivism and rigidified descriptivism (e.g., Kroon, 1987; Lewis, 1997; Jackson, 1998a) claim that the cognitive content of "water" is identical between Oscar and Twin Oscar: "water" is short for something like "the (actual) watery stuff of our acquaintance" for both of them. Such a view would count as an externalist theory of extension but an internalist theory of meaning: the meaning of (say) a proper name or a natural kind term would be internally determined, in that the corresponding expressions used by internal duplicates would have identical meanings.[8] In effect, this is to say that the meanings of the expressions in question have an implicit indexical element,

which they inherit from the explicitly indexical expression "our acquaintance." Internal duplicates could then be said to use their expressions with the same meanings in the same sense as different speakers using the personal pronoun "I" are, in one sense, using it with the same meaning. When the relevant intensions are construed as functions from *centered* possible worlds to extensions (and truth-values), they will be shared between internal duplicates.[9]

The combination of an internalist and an externalist element about meaning and extension, respectively, is explicitly stated in two-factor theories such as Fodor's (1987) or Loar's (1988). More recently, two-dimensionalists such as Jackson (1998b) and Chalmers (2006) have distinguished between two different components of meaning, primary and secondary intensions, where the former are shared between internal duplicates, but the latter may differ (and do differ, in Twin Earth-style situations), due to differences in the physical and/or social environment. Again, this counts as externalism about extension, but if one holds (cf. Jackson, 2004) that what is communicated is determined by primary intensions, the view is internalist about (communicated) meaning.

As noted in the previous section, many philosophers follow McGinn and Burge in taking Twin Earth-style argumentation also to establish *cognitive* externalism, or externalism about *thought contents*. A similar distinction between externalism about the extensions of one's concepts, or about the truth-conditions of one's intentional mental states on the one hand, and externalism about the cognitive content of one's intentional mental states on the other hand can and should be drawn here, as well.[10]

4 How Should the Supervenience Base Be Extended?

Semantic externalism claims, then, that a speaker's intrinsic properties are not sufficient as a supervenience base for the semantic properties of the terms used by the speaker. Externalism, as a general failure-of-supervenience thesis, is silent on what should be added to intrinsic properties of a speaker, to find a sufficient supervenience base. At the same time, the classic thought experiments were already formulated in ways that strongly suggest particular views regarding what should be added to the supervenience base. The additions can be thought of either as relational properties of the speaker or as properties possessed by various objects, kinds, processes, and so on in the speaker's environment – for my purposes here this choice does not matter.

The Twin Earth thought experiment, if successful, establishes *natural kind* externalism, or *physical* externalism. This is the view that the semantic properties of natural kind terms such as "water" supervene on the intrinsic properties of speakers, *plus* some features of the natural world that the speaker is causally interacting with. Typically, such features are thought of as intrinsic properties of physical objects (such as molecular structures, DNA sequences, and so on). But there is no obvious reason why the relevant properties of the physical objects might not themselves be relational – indeed, in the case of biological species, this is how they should be thought of, given the current state of mainstream biology and philosophy of biology.[11]

There is an unfortunate tendency in discussions of natural kind externalism to assume that the relevant features *have* to be construed as micro-structures, or more generally as underlying intrinsic properties, and even to ridicule natural kind externalism for assuming an outdated and oversimplified view of the scientific facts. It is true that Kripke and Putnam

assumed, at least for the purpose of illustrating their externalist views, that the relevant external features are simple and unified underlying features. But as far as semantic externalism, construed as a failure-of-supervenience claim, is concerned, it simply does not matter whether the external features in the supervenience base are intrinsic properties of members of the kind such as micro-structures, or extrinsic ones such as lineages, or something wholly different. All that matters, for externalism as a general claim, is that the added features are external to the individual speaker.

Burge's "arthritis" argument and Putnam's "elm/beech" argument point to another kind of semantic externalist claim, *social externalism*. This is the view that the supervenience base for propositional content has to include other members of one's linguistic community. There are in fact two quite different versions of this claim. On the first, the extensions or meanings of a speaker's expressions are dependent on the intrinsic states of a definite set of other speakers – this is the case when there are clear *experts* that a non-expert speaker is deferring to. Both Putnam's elm/beech example and Burge's arthritis example fall into this category: Putnam is unable to tell elm trees and beech trees from each other, but manages to refer to elm trees with tokens of "elm" because his linguistic community includes experts (botanists, or maybe gardeners), who *are* able to distinguish the trees from each other.

On the second version of the social externalist claim, the extensions or meanings of a speaker's expressions are dependent on patterns of usage in the speech community of which one is a part, without an assumption that some individual speakers should be designated as experts, and deferred to as such. If Burge's argumentation can, as he claims, be extended to color terms and artifact terms, the social externalist view that follows would, arguably, fall in this category – no special expertise is needed, for example, to recognize sofas and distinguish them from non-sofas, or to distinguish the colors from each other.[12]

5 Why Should We Accept Externalism?

If externalism is true of at least some of the linguistic expressions we use, *why* is it true of them? Moreover, if different kinds of externalism (physical, social, and so on) are true of different expressions, what makes this the case? Why is it, for example, that physical externalism about extension (arguably) holds for "water," but not for "bachelor"?

Relatedly, what kinds of methods should we use in finding out which kinds of externalist theses (if any) are true, and of which expressions? We have seen above that thought experiments have in fact played a central role in the argumentation for externalist views, but is thought experimentation a good method? And, supposing that it is at least an acceptable method, is it the best method available to us, or can we improve our methodology by supplementing or even replacing thought experimentation with 'real' experimental methods, as recently urged by experimental philosophers?[13]

We saw earlier that thought experimentation concerning internal duplicates can at most establish externalism about extension, not externalism about meaning. Although the latter view follows from the former together with the widely shared assumption that meaning determines extension, it is possible to be an externalist about extension and yet deny externalism about meaning. But what about the former view, externalism about extension? It is practically certain that there are no actual pairs of speakers who are one another's internal duplicates, so we cannot empirically investigate such duplicates. And even if we could, how would we establish whether the extensions of their expression tokens were identical or not?

It is simply not clear how this should be done – the extensions of one's terms are not directly observable. Any concrete suggestion for how we *should* go about investigating whether the extensions are identical or not will already need to commit to substantial views in meta-semantics. Similarly for any attempt to judge whether, and why, thought experimentation should be thought of as a good source of evidence for and against externalism.

A common way to explain the role of thought experimentation in philosophical semantics is roughly as follows. In thought experiments we elicit *intuitions* about the reference of linguistic expressions in possible scenarios. If, when considering an imagined scenario, we have an intuition that a certain object, substance, or sample (etc.) would belong to the extension of a given term, then that intuition is evidence for theories which would include this object, substance, or sample (etc.) in the extension of the term, and evidence against theories which would not. Likewise, if intuition tells us that a given entity would *not* belong to the extension of a term, then that intuition will be evidence against theories which would include that entity in the extension of the term, and evidence for theories which would not.

But what, exactly, are such intuitions? And why should we think that intuitions – whatever they are – reliably inform us about the extensions of our terms? If we have learned anything from the meta-philosophical debates about intuitions during the last 10 years or so, then it is that the term "intuition" may be doing more harm than good here (Cappelen, 2012). In considering thought experiments such as Twin Earth, we are not (at least not obviously) struck by a mental state with a special phenomenology, compelling us to accept Putnam's verdicts about tokens of "water," as used by Oscar and Twin Oscar. Nor do (or should) we take the judgments we arrive at, concerning thought experiments, as infallible. Nonetheless, when considering such thought experiments, most philosophers do report arriving, with minimal effort, at judgments concerning the extensions of terms in the scenarios imagined. But the minimality of our effort does not tell us whether and why such judgments should be trusted as evidence.

The recent debates around experimental philosophy should make us careful in assuming that such judgments are shared by all, or even most, speakers in one's linguistic community. Whatever one's opinion is about the seriousness of the experimental challenges that have actually been presented so far, one cannot simply assume that one's own judgments are universally shared – we need to know what to conclude if it turns out that judgments about, say, the Twin Earth thought experiment are subject to variation between cultures, socio-economic backgrounds, gender, and so on, or that they are, for example, only shared by philosophers with a certain kind of education, or with certain theoretical preferences.

Various different reactions to such variation are possible (for a useful overview see Horvath, 2010), and it should not be assumed without argument that the same kind of reaction will be appropriate in all the subfields of philosophy where reactions to thought experiments have been experimentally studied. When it comes to philosophy of language, and the debate between internalism and externalism in particular, it will be helpful to take a step back and bring in yet another internalism/externalism distinction: the distinction between *meta*-internalism and *meta*-externalism about reference, introduced in Cohnitz and Haukioja (2013). These views are concerned with the question: What makes it the case that the semantic externalist and internalist views described in previous sections have the truth-values that they in fact have? Semantic externalism and internalism, as we have seen, are views about what kinds of factors are involved in determining the extension or meaning of an expression. Meta-internalism and meta-externalism are views about what *makes it the case that* such factors are so involved. Meta-internalism is the view that the fact that a

semantic internalist or externalist theory is true of a given expression is determined by some intrinsic properties of the speaker in question. Meta-externalism is the denial of this: according to meta-externalism, such facts are *not* determined by intrinsic properties of speakers.

This distinction, too, can be formulated in terms of duplicates. Are the same theories of reference and meaning always true of the phonetically and syntactically identical expression tokens used by internal duplicates? For example, is it possible that internalism about reference and extension is true of the tokens of an expression as used by A, while externalism about reference and extension is true of the corresponding tokens as used by A's duplicate, B? Or, less dramatically, is it possible that different externalist theories are true of the tokens used by A and B (maybe the different versions of social externalism mentioned in §4)? According to meta-externalism, this is possible, while according to meta-internalism it is not. A meta-internalist will claim that, although the *extensions* of syntactically and phonetically identical expressions used by A and B may differ (if semantic externalism is true), the extensions are determined in the same way, and thereby the same internalist or externalist theory is true of the expressions.

Semantic externalism and meta-externalism have generally not been carefully distinguished from each other. Accordingly, explicit statements of meta-externalism are not easy to find: however, some fairly clear commitments to meta-externalist views can be found, for example, in Cappelen and Winblad (1999) and Ludlow (2003). Moreover, an unstated meta-externalist background assumption seems to be present in some of the recent debates concerning the role of experimental data in philosophy of language.[14] Cohnitz and Haukioja (2013) argue that meta-externalism should be rejected, because it fails to explain the role that reference has in the explanation of successful communication: if meta-externalism were true, there might be systematic mismatches between what linguistic expressions refer to, and what information is successfully communicated by competent speakers using such expressions. I cannot in this chapter undertake a full critical evaluation of meta-internalism and meta-externalism. Rather, I will focus on the consequences that a meta-internalist view would have on the methodological questions raised above, and suggest that a certain kind of meta-internalist view can make good sense of the use of thought experiments in arguing for and against externalism about extension.

A *dispositionalist* version of meta-internalism claims that the fact whether a given semantic internalist or externalist view is true of an expression as used by a speaker is supervenient on that speaker's dispositions to apply and interpret that expression – including the speaker's dispositions to apply and interpret the relevant expressions in conditions that are non-actual, as well as the speaker's dispositions to revise his or her application and interpretation in response to empirical information.[15]

Let us look at examples. For some of the expressions we use, such as "bachelor," our patterns and dispositions of application and interpretation are unaffected by contingent features of the natural world around us. The properties that speakers – individually or collectively – associate with the expression are sufficient for determining whether the expression applies to a given individual or not. With other expressions we have dispositions to 'shift the burden' of determining their applicability partly to external factors. In the case of "water," for example, we have dispositions to evaluate the correctness of actual and counterfactual applications of the term according to whether or not the term is applied to samples which share the underlying structure of the substance that is causally connected in the appropriate way to our actual usage of "water" (or something similar: the details will

depend on one's preferred theory of reference). We also have dispositions to *re*-evaluate our application of such terms in the face of new empirical information about what the world is like.

To illustrate, suppose that we took a representative sample of bachelors, studied them empirically, and found out that every single one of them has a certain neural structure – call it N – while no individuals outside the sample have N. Would we then start to categorize people as bachelors in other possible worlds according to whether or not they have neural structure N or not? Surely not. That is just not how "bachelor" works: we would go on categorizing people as bachelors, in the actual world as well as in counterfactual ones, according to their age, gender, and marital status.[16]

According to dispositionalist meta-internalism, social externalism arises in a similar fashion, through deferential dispositions. For example, I can refer to elm trees with my term "elm," even though I cannot tell them apart from beech trees, on the basis of my dispositions to defer to people who can actually tell elms apart from other trees (e.g., botanists or gardeners). Should I find that my classification of trees into elms and beeches differs from that of an expert, I would immediately be disposed to revise my earlier application of the terms and align my usage with the expert. In other kinds of cases, I might not be disposed to defer to any particular speakers and their usage, but rather be disposed to align my usage with that of the majority, and further to revise my earlier applications, should I find out that my usage was not in line with the majority. The fine details of our dispositions to apply and interpret, and to revise our application and interpretation, may be controversial. But if dispositionalist meta-internalism is true, the true theory of reference for a given expression is determined by precisely such dispositions.

If such a dispositionalist meta-internalist picture can be developed in detail, it promises to make it quite non-mysterious why thought experiments should be a valuable source of data for philosophy of language. On this view, semantic internalism and externalism are ultimately claims about complex patterns of dispositions that we have with respect to the expression, or class of expressions, in question: patterns to apply and interpret them, as well as to re-evaluate our past application and interpretation. Twin Earth-style thought experimentation is precisely a project in which one introspectively accesses such dispositions. Such thought experiments can be understood as a kind of mental simulation: we imagine finding ourselves in various metaphysically possible situations and ask ourselves whether or not we would be disposed to apply a given expression to a given entity (or substance, state, process, etc.), and how, if at all, we would reconsider our classifications in the face of various imaginable empirical findings, or in the face of finding ourselves disagreeing with others in our community, and so on. In doing this, we are not relying on empirical evidence, but rather activating our own dispositions in simulation. Thought experimentation can give us direct, though not infallible, evidence about the kinds of dispositions we in fact have.

That the primary evidence from thought experiments concerns our linguistic dispositions is easily clouded by the fact we often *report* the results of thought experimentation as generalizations. As a response to the Twin Earth thought experiment, we say that our term "water" refers to H_2O but not to XYZ, and vice versa for Twin Oscar's tokens of "water." But in considering the thought experiment, we are primarily probing our own dispositions to apply and interpret the relevant terms in a range of particular situations, our dispositions to revise our usage in response to various possible empirical outcomes, and so on. I suspect that most people who have discussed the Twin Earth thought experiment with non-philosophers (or taught it to students) have found that, if speakers are at first

unsure what to say about the case, getting them to think about particular application and interpretation situations will help them to see the relevant patterns.[17] On the dispositionalist meta-internalist view I'm suggesting here, saying that our term "water" refers to H_2O but not to XYZ (given that our world is an H_2O world) is really to report a generalization over such patterns.[18]

None of this, of course, answers the worries raised above, about possible variation in the relevant kinds of linguistic dispositions – we cannot simply assume that everyone else in our linguistic community shares our dispositions. On the view I am suggesting, the facts about reference and extension are determined by the patterns of dispositions that speakers actually have, and the precise nature of such dispositions is, clearly, an empirical question. However, it is far from clear that the kinds of experimental setups that experimental philosophers have primarily been using – survey studies where non-philosophers react to thought experiments – are the best way to study such patterns empirically. The kinds of thought experiments that have figured prominently in the internalism/externalism debates, in particular, are *philosophers' tools*: experiments formulated by philosophers *for* other philosophers who are already familiar with the competing theories and who are thereby able to focus on the relevant features of the scenarios that are (often sketchily) presented. To get more informative data, more sophisticated experimental setups should be developed (cf. Cohnitz and Haukioja, 2015).

The above discussion has concentrated on our reasons to accept externalism about extension. As noted earlier, externalism about *meaning* does not get the same degree of immediate support from considerations concerning internal duplicates. Here, a lot will turn on exactly what we expect a theoretically useful notion of meaning to do. Evidence about language use and dispositions to language use, whether collected by thought experimentation or 'real' experimentation, will not be as directly relevant here as it is for internalism and externalism about extension: rival theories of meaning – for example, a Putnamean theory and a causal descriptivist theory – may agree completely on extensions across possible worlds, but disagree on which phenomena a theory of meaning should primarily explain, or how the relevant phenomena are best explained.[19]

* * *

When it comes to the debates between internalism and externalism about extension as well as meaning, the battle lines between the opposing views have been quite clear for some time. But when it comes to the foundational and meta-philosophical issues I have touched upon in §5, they are much less so. I have here suggested one way of thinking about the foundational and methodological issues – future progress in the first-order debates about extension and meaning will, I believe, crucially depend on increased understanding of such foundational questions, not least the proper role, if any, of experimental results of various kinds.

Notes

1 This particular formulation can be found, for example, in Jesper Kallestrup's excellent recent book on semantic externalism (Kallestrup, 2012, p. 62).

2 Descriptive semantics is concerned with what meanings, or semantic values, the expressions of a language have, and how the meanings of complex expressions are determined by the meanings of their parts. Foundational semantics is concerned with what makes it the case *that* a language has the descriptive semantics that it in fact has. (See Chapter 35, REFERENCE AND NECESSITY.)

Sometimes the label "semantic externalism" is also used of views within descriptive semantics, namely, the view that the semantic values of some expressions are object-dependent. For discussion of the relationships between the views, see Wikforss (2008).

3 Although Twin Earth is often presented as a planet in another possible world, in Putnam's original presentation Twin Earth exists in *our* world, "somewhere in the galaxy" (Putnam, 1975, p. 223). However, in the discussion leading up to his thought experiment, Putnam notes that according to the traditional view he wants to reject, the meanings of terms used by internal duplicates (speakers who are in "the same psychological state in the narrow sense") in different "logically possible worlds" should be identical (p. 221). In discussions of thought experiments like Twin Earth, it is common to assume that it does not make much difference whether we adopt a "cross-world" or an "intra-world" interpretation of the scenarios. The differences *can* sometimes be highly important, however, for example in evaluating versions of descriptivism that aim to capture Putnamean judgments about reference in such cases, but this issue will not be examined here. For simplicity, and since I'm understanding semantic internalism and externalism as claims concerning supervenience (and since supervenience is standardly understood as a modal notion), I will here mostly adopt the cross-world interpretation.

4 I find it almost certain that the Earthian spaceship would *not* give a report on the *meaning* of the term "water" on Twin Earth. Rather, they would be more likely to report along the following lines: "Contrary to what we first thought, there is no water on Twin Earth, but rather a remarkably similar substance, XYZ." I will return to this below, in §5.

5 In Putnam's original example, Oscar_1 and Oscar_2.

6 There are, of course, complications to be worked out, even if one agrees with Putnam. For example, there is the uncomfortable fact that we Earthlings consist of 50–65% water. This worry is typically quickly dismissed as merely having to do with Putnam's choice of example. While I agree that the worry can be side-stepped in this way, I do think that the ease with which we dismiss it points to a more fundamental worry concerning how we should understand internal duplicates in discussions of externalism: perhaps the respect in which internal duplicates should be *duplicates* should not be thought of as identity of physical constitution, but rather as something like *subjective indistinguishability* (cf. Farkas, 2003).

7 The qualification "across possible worlds" is crucial. Classical descriptivism is a paradigm example of semantic internalism, yet any descriptivist should be happy to grant that the *local* extensions of phonetically and syntactically identical *definite descriptions*, used by internal duplicates, may differ: accordingly, so will the extensions of the terms covered by a descriptivist theory.

8 Externalists about meaning do, of course, have arguments against such proposals (beginning with Kripke's semantic and epistemological arguments), but such arguments are no longer driven by thought experiments featuring internal duplicates. Accordingly, externalism about meaning goes beyond what is immediately established by Twin Earth-style thought experimentation.

9 A centered possible world consists of a possible world, an agent in that world (here, the speaker), and a point in time. For further discussion of details of a theory of this kind, see Kallestrup (2012, pp. 102–105).

10 Relatedly, John McDowell (1992) argues that the proper lesson to draw from Putnam's Twin Earth thought experiment is that psychological states should not be thought of as *narrow* states, but rather as partly individuated by external factors: on such a conception of mental states, one can accept both that meaning determines extension, and that grasping a meaning is a matter of being in a certain psychological state. Such cognitive externalism, just as Burge's, concerns the individuation of mental content, and is often called *content* externalism. A more radical kind of cognitive externalism, *vehicle* externalism, claims that the contentful mental states themselves extend "outside the skull" – Clark and Chalmers's "Extended mind" thesis (Clark and Chalmers, 1998; Clark, 2010) is arguably the best-known example of vehicle externalism. (The term "vehicle externalism" is due to Hurley, 1998.)

11 There is nothing very surprising about this – after all, Kripke argued for the essentiality of origin for material objects, including organisms, so in the case of proper names the relevant "underlying properties" will be relational ones.

12 An interesting recent extension of social externalism that cuts across this division is also worth noting. *Temporal* externalism claims that the contents of our expressions can be partly dependent on contingent future events, whether these be future decisions made by a group of experts, or future trends and patterns in the linguistic community as a whole. For a defense of temporal externalism, see Jackman (1999); for critical discussion see Brown (2000), Jackman (2005), and Stoneham (2003).

13 For an excellent critical review of experimental philosophy of language, see Hansen (2015).

14 See, for example, the exchange between Machery (2011) and Devitt (2011) – both seem to assume that the semantic facts are constitutively independent of the linguistic judgments and dispositions of competent speakers.

15 A full defense of dispositionalist meta-internalism would require a discussion of whether and how the Kripkensteinian arguments against dispositionalism (cf. Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING) are relevant. A lot will turn on how we understand Kripkenstein's challenge and his distinction between straight and skeptical solutions, on whether meta-internalism is a reductive view in the relevant sense, and related issues: this discussion clearly falls outside the scope of the present chapter. However, my suggestion for how the distinction between semantic internalism and externalism arises on a dispositionalist meta-internalist view is inspired by a dispositionalist response to Kripkenstein that makes use of dispositions on two levels: dispositions to apply and interpret linguistic expressions, as well as dispositions to re-evaluate and correct one's application and interpretation in the face of new empirical evidence about the world and/or about the linguistic behavior of other speakers (cf. Pettit, 1996; Haukioja, 2005).

16 Or, consider another version: suppose that we found that, say, 99.7% of unmarried adult males have N, while 0.3% do not; at the same time, we find N present in a tiny proportion of married females. Would we revise our categorization of this small minority of men as bachelors and instead include the married females? Surely not. (Thanks to Daniel Cohnitz for this twist on the example). Were we to make a similar discovery about the golden stuff, say that we find some of the metal we categorized as gold to have a different atomic number than 99.7% of the rest, while a small sample of a greenish looking metal turns out to have the same atomic number as the other 99.7%, we would, I think, revise our categorization of the 0.3% and consider the greenish stuff as gold.

17 Indeed, this is precisely what Putnam does with his story about astronauts reporting back to Earth. The crucial dispositional facts here concern the astronauts' retraction of their earlier applications of "water" to samples of XYZ, when they become aware of the relevant chemical facts (cf. n. 4).

18 The judgments we report are, then, generalizations over non-inferential responses. Here I disagree with Cappelen (2012), who insists that the crucial judgments we arrive at in response to philosophical thought experiments are ordinary inferential judgments. Cappelen bases this claim on the fact that philosophers typically, after having presented a judgment about an imagined scenario, go on to give *reasons* or *arguments* for the judgment. Putnam is no exception: after presenting the Twin Earth thought experiment he goes on to hypothesize that the difference in the extensions of Oscar's and Twin Oscar's tokens of "water" is due to the fact that the extension of "water" consists of samples that bear the same relation to most of the stuff we call "water." But I think this is to misconstrue the role of such hypotheses. Putnam is not presenting an argument, drawing on common ground, to *convince* his reader that our "water" refers to H_2O but not to XYZ; rather, he is presenting a *diagnosis*, that is, putting forward a hypothesis about which factors our usage of "water" is in fact sensitive to.

19 Empirical and experimental data will potentially be relevant here, too, but the details will heavily depend on theoretical considerations. For example, Nichols, Mallon, and Pinillos (2016) have recently argued, based on experimental evidence, that natural kind terms are systematically ambiguous between internalist and externalist readings.

Essentialism

GRAEME FORBES

1 Concepts

The term "essentialism" in its popular usage is usually qualified in some way, as in "biological essentialism," "gender essentialism," "social essentialism," and so on. The three views just mentioned are typical: they are all views about human nature, and their general thrust is that in certain respects people *have* to be the way that they in fact are, in virtue of, respectively, their genes, their sex, or the social class to which they belong. Usually the respects in question are politically controversial though there are also interesting examples with no real political overtones, for instance, Chomsky's view that it is part of the "human essence" to be capable of learning only languages whose syntactic rules satisfy the constraints of certain "linguistic universals" (Chomsky, 1988, *passim*). The general idea here is that for each thing of a particular kind there are various apparent possibilities for it which are in fact closed off in virtue of its possessing such-and-such a property, where the property mentioned is characteristic of the kind of essentialism being propounded. For instance, a human being may be said to be unable to partake in interpersonal relationships of a particular emotional timbre because that human being is male.

Contemporary *metaphysical essentialism*, which is our main concern here, consists in a variety of more abstract doctrines of this broad sort. Certain apparent possibilities for things are argued to be not genuine possibilities for them. However, the possibilities are closed off not in virtue of features of the things concerned as specific to them as, say, social class is to human beings in contemporary Western societies, but rather, in virtue of the very nature or identity of the thing. To be more specific, we may explain the idea of a *metaphysically essential property* in terms of Aristotle's "essential/accidental" contrast. According to Aristotle, an accidental property is "something which may possibly either belong or not belong to any one and the self-same thing" (Aristotle, 1928, 102^{b}5ff.). This can be firmed up in two slightly different ways. Assuming that an accidental property of x is a property that x in fact possesses, we may say either

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

(1) *P* is an accidental property of *x* iff (i) *x* in fact possesses *P* but (ii) there is a way things could have gone according to which *x* lacks *P*;

or

(2) *P* is an accidental property of *x* iff (i) *x* in fact possesses *P* but (ii) there is a way things could have gone according to which *x* exists and lacks *P*.

We may then define *P* to be an *essential* property of *x* if *x* in fact possesses *P* but *P* is not an accidental property of *x*. Metaphysical essentialism is more fundamental than the specific kinds of essentialism mentioned above, since these latter typically depend upon (alleged) features of human nature which are themselves accidental, so in ways things could have gone in which human beings do not have those features, they would not have to have the "essential" properties that depend on them.

What hangs on the difference between (1) and (2)? The problem with (1) is that it threatens to make all properties accidental, for an uninteresting reason, at least in the case of things which might not have existed. As we will see, the examples of essential properties that have captured most attention in contemporary philosophy are properties which are *existence-presupposing*: necessarily, if *x* has one of these properties, then *x* exists. But if *x* is a contingent being, one which might not have existed, there are ways things could have gone according to which *x* does not exist, and consequently, in any of these ways things could have gone, *x* lacks all the candidate essential properties, thereby demonstrating that they are not essential to *x* after all. But this seems merely to miss the point, and so one turns to (2) as a superior definition. Unfortunately, (2) also has its flaws, chief among which is that it makes *existence* an essential property, since there is no way things could have gone according to which *x* exists and lacks existence. So neither (1) nor (2) exactly captures the notion we are after. Why this should be so is itself an interesting question to which we shall return. For the moment, we simply observe that if we are to stay with (2), we will want to distinguish between *trivially* and *non-trivially* essential properties, with existence as the paradigm of the trivially essential. How this distinction is to be drawn is itself non-trivial.

The other main concept with which we will be concerned is that of an *individual essence*. Intuitively, the essence of a thing is the collection of its features which determine its identity, which make it the specific thing it is rather than something else. One way of articulating this idea is embodied in the following definition:

(3) *e* is the (*individual*) *essence* of *x* iff *e* is a set of properties such that each member of *e* is an essential property of *x* and it is not possible for any other object *y* to possess all the properties in *e*.

However, (3) is subject to an irritating technical defect of the same flavor as those afflicting (1) and (2), for there is nothing in any of our definitions which warrants the phrase "*the* essence" in (3). That is, there is no apparent reason why there should not be two different sets of properties *e* and *e′*, each satisfying the condition for being an essence of *x*. So (3) really ought to begin "*e* is *an* essence of *x* iff…." We shall return later to work of Kit Fine which motivates a different approach to the ideas of essence and essential property by emphasizing these difficulties with (1), (2), and (3). But for the moment we shall stay with the modal approach, the definitions in terms of possibility and necessity.

2 Essentialist Theses and Arguments for Them

The contemporary debate about essentialism was provoked by writings of Kripke (1972; 1980) and Putnam (1975), with subsequent contributions by Fine (1977) and Wiggins (1980). According to Kripke, the origin of an organism *o* is essential to it, and the matter from which an artifact *a* is fashioned is essential to it; or at least, neither the origin of *o* nor the matter of *a* could be entirely different from what it actually is. According to Putnam, the fundamental physical properties of substances are essential to them: a particular substance could not have had a totally different fundamental nature. For instance, there is no way things could go in which an actual chemical compound comes into existence with a molecular structure quite different from the structure it actually has. According to Fine, it is essential to a set to be a set and to have the members it actually has: a set is not to be conceived of as a box, which actually has one range of members, the odd numbers, say, but, if things had gone differently, would have had a different range of members, the even numbers, say (Fine, 1981). Finally, Wiggins has argued for the view that the "natural kind" (if any) to which *x* belongs is essential to *x* (1980, ch. 4). Thus he, Wiggins, as a human being, could not have been a polar bear, or a forest, or a performance of Beethoven's Ninth Symphony.

These claims have struck an intuitive chord in many philosophers. If we grant the essential/accidental distinction in the first place, then it is plausible that it is essential to Wiggins that he is not a performance of Beethoven's Ninth, but not essential to him that he is a professional philosopher (he might have pursued a different career). However, the interesting question concerns not so much whether a particular essentialist thesis is true, but rather what principles are employed in drawing the essential/accidental distinction in particular cases. Indeed, an independently plausible account of the principles should feed back to help decide some of the more controversial theses.

For purposes of uncovering principles we can sort the various doctrines into two groups: those which posit essential connections between specific individuals, such as the connection between a set such as {0} and its member 0 and between a tree and the seed from which it originated, and those which make a thing's kind essential to it, such as the claims that sets are essentially sets and humans essentially human. We begin with the first group, involving essential connections between specific individuals, and we take as a stalking-horse Kripke's proposal about the essentiality of origin, as formulated in the following famous passage (1980, pp. 112–113):

> The question really should be … could the Queen – could this woman herself – have been born of different parents from the parents from whom she actually came? Could she, let's say, have been the daughter … of Mr and Mrs Truman?… We can imagine discovering [that the Queen was the daughter of Mr and Mrs Truman] … But let us suppose that such a discovery is not in fact the case. Let's suppose that the Queen really did come from these [her actual] parents… can we imagine a situation in which it would have happened that this very woman came out of Mr and Mrs Truman? They might have had a child resembling her in many properties … [perhaps] … even … a child who actually became the Queen of England and was even passed off as the child of other parents. This still would not be a situation in which *this very woman* whom we call "Elizabeth II" was the child of Mr and Mrs Truman, or so it seems to me. It would be a situation in which there was some other woman who had many of the properties that are in fact true of Elizabeth… How could a person originating from … a totally different sperm and egg, be *this very woman?*

The question is somewhat rhetorical, but as Kripke develops his example it has considerable force, and I have never seen a convincing counter-example to the underlying thesis. This thesis is that if an organism *o* originates from a cell *c* – a fertilized egg or *zygote*, in the case of human beings – then it is essential to *o* that it originate from *c*: *o* could not exist except by originating from *c*. We will call this thesis the *essentiality of origin*. However, to find the essentiality of origin plausible and alleged counter-examples to it unconvincing is one thing; but to have a theoretical explanation of why it is true is another.

To find such an explanation we can consider some of the consequences of rejecting the essentiality of origin. If the thesis is false, then even if in the actual world *o* develops from *c*, there is a way things could have gone, an *alternative possible world*, in the popular jargon, in which *o* exists, but as a result of developing from a different cell *c′*. Let *w* be such a world, and for the sake of the argument let us suppose that *o* is as similar as possible in *w* to the way it is in the actual world. Let us also grant that there are no special connections between how things can go for *c* and how things can go for *c′*, other than that *c* and *c′* cannot both give rise to the same organism in the same possible world. Then there is a world *u* where *c* and *c′* both give rise to organisms; we use *r* for the organism to which *c* gives rise in *u*, and *g* for the organism to which *c′* gives rise in *u*. Let us pick such a *u* with the special feature that *g* as it is in *u* is as similar as possible to *o* as it is in *w*. The total setup is given in Figure 34.1.

We have refrained from making any suppositions about which, if either, of the organisms in *u* is identical to *o*. But in the logic of the situation, there are only three possibilities: (a) *o* is identical to *g*; (b) *o* is identical to *r*; and (c) *o* is identical to neither *g* nor *r*. The consideration which favors the essentiality of origin is that all three of these options seem to have undesirable consequences, and so the hypothesis which generates them, that there are worlds where *o* develops from different cells (such as the actual world and *w* in the figure), is to that extent disconfirmed.

Postponing discussion of (a) for the moment, the problem with (b) and (c) is that the hypothetical non-identity of *o* and *g* is hard to accept, since *o* and *g* are *intrinsic* and *spatio-temporal* duplicates: by this I mean that they have the same nature and occupy the same places at the same times. Indeed, they need differ only in the extrinsic respect that *g* in *u* is existing in a world where *c* gives rise to an organism, while *o* in *w* is not, and in other extrinsic respects which are a consequence of that one. If we were asked to imagine a course of events which differs from *w* in that *c′* gives rise to an organism different from *o*, but that is the totality of the difference – no difference in any features of the two worlds is to be admitted, only a difference in the pure identity of the thing to which *c′* gives rise – we may wonder what content could be given to the idea that *c′* becomes *different* things in the two worlds. But if the idea that the organisms into which *c′* grows in the two worlds are different is of dubious intelligibility in this example, it is hard to see how throwing in *c* and an organism it develops into can make any difference to the intelligibility issue. The objection to world *w*, then, on either (b) or (c), is that it implies the existence of a numerical difference between entities in distinct worlds where there are no intrinsic features of these entities to support the posited difference.

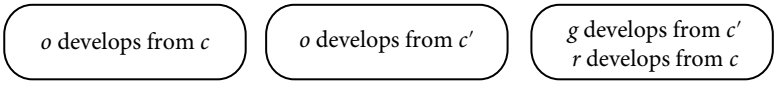

Figure 34.1

This still leaves the skeptic about the essentiality of origin with (a), that *o* is identical to *g*. However, under plausible assumptions, (a) has the same problematic aspect as (b) and (c). For there seems to be no reason why we cannot choose a world *v* in which *o* develops from *c* in the same way, and at the same places and times, as *r* does in *u*. That is, there is a world *v* in which *o* develops from *c* in such a way as to make it an intrinsic and spatio-temporal duplicate of *r* in *u*, since this only requires that the intrinsic and spatio-temporal features of *r* in *u* are ones all of which could have been possessed by *o*, excluding only those which involve the phenomenon at issue, such as being in a world in which something other than *o* develops from *c*.

This style of argument can be repeated for some of the other examples of essential properties we mentioned earlier. If we allow that a set could have different members, or that an artifact could have been made from entirely different parts, or that a substance could have had different fundamental physical properties, we can, under natural assumptions, generate analogous sorts of duplication without identity, as the reader may confirm. But this leaves us short of a *proof* that these properties are essential. Returning to the essentiality of origin, if intrinsic and spatio-temporal duplication of the sort manifested in our example implies identity, then any view which generates intrinsic and spatio-temporal duplication without identity is to be rejected. But this is insufficient to establish the essentiality of origin, since there are other properties which, if essential to *o*, would rule out intrinsic and spatio-temporal duplication without identity. For example, it might be proposed that the route through space which *o* traces while it exists is essential to *o*. If so, there is no world *v* such as is appealed to in the previous paragraph, and we can settle on (a). For in the actual world, in *w*, and in *u*, *o* must trace the same route; hence in *u*, *r* is spatio-temporally distinguishable from *o* in the actual world, and hence *r*'s route is not a possibility for *o*.

There is, of course, no plausibility in the hypothesis that an ordinary material object's spatio-temporal nature (its location at each time of its existence) is essential to it. The interesting question is why this is so. The kind of relationship in which an organism stands to its originating cell seems bound up with that organism's identity in a special way. It would go too far to say that the relationship is itself identity. A human being, for example, is not *identical* to the zygote from which he or she develops, since the zygote ceases to exist when it divides, while the human being does not cease to exist then. We may, if we wish, speak of a human's *zygotehood* on analogy with childhood (McGinn, 1976), but this simply raises the question of why the identity of the cell that constitutes the body during zygotehood should be any less accidental than the identities of the cells that constitute it during childhood. Nevertheless, the relationships between a set and its members, an organism and its zygote, and an artifact and the matter of which it is constituted (for example, a bronze statue and the bronze from which it is molded) do appear to have a certain affinity: they have an internal aspect which spatio-temporal relations lack. We will return to this later in our discussion of the source of necessity.

The kind of defense given here of the essentiality of origin is less obviously applicable in defense of Putnam's essentialism about the fundamental physical properties of substances. Could water exist in a universe where matter is continuous? Assuming that the fundamental property of water is not just to have a chemical composition of two parts hydrogen to one part oxygen, but rather to have molecules consisting in two hydrogen atoms and one oxygen atom, and hydrogen and oxygen themselves are fundamentally constituted of particles which are not further divisible, there could be nothing in a universe of continuous matter satisfying the description abbreviated by "H_2O." But perhaps water could exist there

as the substance fulfilling certain functions actually instantiated by H_2O. Suppose that we can make sense of the idea of functions that are performed by some substance in the actual world and again by some substance in a world where matter is continuous. Then we might argue, on Putnam's side, that this is still not sufficient for identifying the substances. But it will be hard to generate a convincing case of objectionable duplication that comes about as a result of making the identification, for this would require a world in which a substance with the physical structure H_2O exists alongside the substance from the world with continuous matter identified as water on functional grounds. At this point, one is less entitled to confidence in the coherence of the possible situations being stipulated than one is in those of the more straightforward case of organisms and the cells from which they develop. Still, this is only to say that a particular way of defending Putnam's thesis is less effective, not that the thesis itself is incorrect.

We turn briefly to the second group of essentialist theses we distinguished at the beginning of this section, those which say that a thing's kind is essential to it, such as the claims that sets are essentially sets and humans essentially human. These essentialist theses are easier to justify, particularly if we consider extreme cases. What could be meant by the suggestion that, say, {0} could have been a tree instead, or that Wiggins could have been Loch Ness? The problem of making sense of such bizarre hypotheses is not just one of lack of imagination. Indeed, there are fantasies in which persons in some sense "turn into" geographical features. But one does not treat these stories as representing genuine possibilities for the objects concerned; merely the same name is used, on the basis of some far-fetched or peripheral similarity. In the same vein, in explaining the layout of a town to someone over the breakfast table, one might say, "Let this pot of marmalade be the railway station." That does not mean that this pot of marmalade could have been a railway station, much less that particular railway station. The problem is that for it to be a possibility for a pot of marmalade to have been a railway station, or for {0} to have been a tree, we have to be able to conceive of two different states of affairs in which one and the same thing figures, in the first as a pot of marmalade or singleton zero, and in the second as a railway station or an item of flora, respectively. However, this in turn means that we would be conceiving of objects and their properties on the model of bare particular and inherence, according to which a thing is a propertyless substratum and can take on any nature you please via the inhering of appropriate properties. But this, if it makes sense at all, is at any rate not the conception which we employ. Articulating our actual conception is another problem, but whatever the right story is in this area (see Wiggins, 1980, chs 3–4), one constraint is that it must imply the fundamental unintelligibility of hypotheses which make the broad kind to which a thing belongs an accidental feature of it.

We have considered some examples of interesting essential properties and what might be said in support of them. An individual essence of an object x was defined in (3) to be a collection of essential properties of x such that if at any world an object y possesses all of them, then y is x. The essential properties we have discussed give rise to individual essences in a completely straightforward way only for sets: if x is a set, then *being a set* is part of x's 'natural' essence, and for each y which belongs to x, *having y as a member* is part of x's natural essence, and no other property is part of x's natural essence. By including *being a set* in the essence, we distinguish x from other entities which also have members and which might, as things actually are, have the same members as x, such as a club. The term 'natural' requires some justification, however. It is also an essence of x to be the sole member of $\{x\}$, at least by the lights of (3); but as Fine has urged (Fine, 1994) this essence is not revealing of x's nature: the kind of thing it is and *which* thing of that kind it is. So it is in that sense not the natural essence.

The analogous proposal for organisms is that each organism has its biological kind and the cell or cells from which it developed as its natural essence. But there are two difficulties. First, in view of the mechanisms by which speciation actually occurs, 'kind,' at least interpreted as 'species,' may be too strong. One would like something more vague here, but how can vagueness enter the specification of a thing's natural essence? Second, some cells arise by division of a parent cell. But if y and z arise in this way from x, all three being cells of some kind K, it is not sufficient to specify the essence of y as being of kind K and arising from x, for z is also of kind K and arises from x. However, y is constituted of part of the matter of x (just before division) and z is constituted of the other part, and it certainly seems wrong to say that y could have been constituted of the matter of which z is actually constituted, all else being the same so far as possible. Hence a plausible move in filling out the account of the natural essences of y and z is to add some constraint about what part of the matter of x each can be constituted of. But it also seems that it is too strong to make *exactly* the actual matter from which y is constituted part of y's natural essence. Surely y could have been constituted of slightly more, or slightly less, or slightly different, matter? Again there is the thought that we need to build some kind of vagueness into the specification of essences. We will see in the next section how this might be done.

3 Slippery Slopes and Primitive Thisnesses

The argument of the previous section claimed to ground certain essentialist theses, such as the essentiality of origin, in principles about "identity across possible worlds." The essentialist theses were defended on the grounds that denying them leads, under plausible assumptions, to pairs of worlds containing objects which are intrinsic and spatio-temporal duplicates and yet which are numerically distinct. But this is a poor defense if careful thought reveals that there is actually nothing objectionable about intrinsic and spatio-temporal duplication without numerical identity. We turn now to two arguments which seek to show that indeed there is nothing to object to in such duplication.

The first argument, due in essentials to Chisholm (1967) and sometimes known as Chisholm's paradox, exploits an intuition of *modal tolerance* in certain features of particular objects (the version I give of Chisholm's paradox is not quite Chisholm's, since he uses iterated modality; but the moral is the same). A watch, for example, which is actually made from a particular collection of parts, might have been made from a *slightly* different collection; it might have had a different winder, say. More abstractly, imagine that we have an artifact x made of parts $p_1, \ldots, p_{20}$, each of which is equally important to its function, and a different artifact y, though of the same design, made of parts $p_{21}, \ldots, p_{40}$. Suppose we now formulate modal tolerance more precisely as

(4) If a particular make-up is possible for a thing, then a slightly different make-up is also possible for it.

Since x is actually made of $p_1, \ldots, p_{20}$, then trivially, that make-up is possible for it (it could hardly be *impossible*!), and so by one application of (4), x could have been made of $p_1, \ldots, p_{19}, p_{40}$. But then by another application of (4) to this result, x could have been made of $p_1, \ldots, p_{18}, p_{39}, p_{40}$. By a further eight applications of (4), we arrive at the following conclusion:

(5) x could have been made of $p_1, \ldots, p_{10}, p_{31}, \ldots, p_{40}$.

However, exactly the same reasoning leads us to the conclusion that

(6) y could have been made of $p_1, \ldots, p_{10}, p_{31}, \ldots, p_{40}$

since y, being actually made of $p_{21}, \ldots, p_{40}$, could have been made of $p_1, p_{22}, \ldots, p_{40}$, and so on, using (4). Since there seems to be no reason why a situation in which (5) is true would have to differ in some other way from a situation in which (6) is true, other than in differences logically consequent upon the difference in identity of the things made of $p_1, \ldots, p_{10}, p_{31}, \ldots, p_{40}$ in the respective situations, we have a striking case of duplication without numerical identity. But the logic that leads us to this point is impeccable, hence duplication without identity is unobjectionable.

One response to this is that in fact there is no duplication without identity, since any situation in which x is made of $p_1, \ldots, p_{10}, p_{31}, \ldots, p_{40}$ is *ipso facto* one in which y is made of $p_1, \ldots, p_{10}, p_{31}, \ldots, p_{40}$ and vice versa; it is just that in such a situation, x and y are the *same thing*. But this response is problematic in a number of ways. First, and most to the point in the present context, it is of little use to the essentialist, who will want to say that it is essential to x and to y to be made of a substantial majority of the parts of which they are actually made: a make-up of $p_1, \ldots, p_{10}, p_{31}, \ldots, p_{40}$ should be impossible for both x and y. Second, it has the strange implication that as things actually are, x is the same thing as any of the merely possible artifacts which could have been constructed using half of x's parts, for there are possible worlds with artifacts other than x with compositions that stand to $p_1, \ldots, p_{20}$ as x stands to the possible composition $p_1, \ldots, p_{10}, p_{31}, \ldots, p_{40}$. Third, on the usual way of understanding possible situations, it is hard to make sense of two things being identical in a possible situation. On the orthodox approach, we begin with a stock of objects whose possibilities we wish to model, and we represent possible situations involving them by selecting some of the objects and configuring them with atomic properties and relations; for instance, if x is selected and given the property P, and if y is also selected and x is given the relation R to y, the model is of the possibility for x of being P and being R to y. Thus if x and y are given from the outset as different things, then using x in the model of a possible situation is different from using y.

A better defense of the principle that intrinsic and spatio-temporal duplication implies identity is to query the logic of the supposed counter-example. It is natural to view (4) as a modal case of a paradox of vagueness, or a *sorites* paradox (see Chapter 28, SORITES). More familiar examples involve vague predicates like "tall" or "bald," or color words. For example, suppose 1,001 people are arranged in descending order of height, beginning with someone two meters tall and ending with someone one meter tall, adjacent people differing in height by one millimeter. The first person in this sequence is tall, the last is short. However, if we accept the seemingly plausible

(7) If x is tall then anyone not visibly distinguishable in height from x is tall

we easily derive, by repeated applications of (7), that the last person in the sequence is tall, though he or she is not. Case (4) is similar, the vague predicate being "_is a possible make-up for x." Whatever the problem is with relying on (7), then, the same difficulty should afflict (4).

However, it is one thing to know that a form of argument is untrustworthy, another to be able to say what theoretical flaw it embodies. There are various accounts of the mistake in the paradox of tallness, but a suggestive idea is that the argument depends on treating tallness as all or nothing: a person is either tall or not tall. Yet tallness is a matter of degree: someone can be tall, very tall, fairly tall, tallish, not exactly tall, and so on. Suppose we regard the various possible heights as correlated with *degrees of tallness* in such a way that different heights, even two that are not visibly discriminable, correspond to different degrees (unless they both qualify their bearers as tall *simpliciter* or not tall at all). The degree to which x is tall may be thought of as determining a *degree of truth* for the statement "x is tall," so that if we are somewhere in the upper third of our line-up, where the people are somewhat tall but also somewhat medium-sized, then "a is tall" will be true to a slightly higher degree than "b is tall" if a is one millimeter taller than b. Suppose also that the degree of truth of a conditional $p \rightarrow q$, when the antecedent has a higher degree of truth than the consequent, reflects the amount by which the truth of p exceeds the truth of q, the conditional's degree of truth dropping as the gap increases (in the limits, when p is not more true than q, $p \rightarrow q$ is wholly true, and when p is wholly true and q is wholly false, $p \rightarrow q$ is wholly false, as in classical logic; if we use the real numbers between 0 and 1 inclusive as degrees of truth, with 0 for complete falsehoods and 1 for absolute truths, then a clause for $\rightarrow$ which satisfies these conditions is: the degree of truth of $p \rightarrow q$, for short "$\deg(p \rightarrow q)$," is $1 - [\deg(p) - \deg(q)]$ when $\deg(p) > \deg(q)$, otherwise $\deg(p \rightarrow q) = 1$). The derivation of our conclusion that the one-meter-tall person in our line-up is tall can be represented as a chain of conditionals, "$\text{tall}(a_1) \rightarrow \text{tall}(a_2)$," "$\text{tall}(a_2) \rightarrow \text{tall}(a_3)$," and so on, the antecedent of the first conditional being given. However, there is now no reason to accept the conclusion "a_{1001} is tall," since somewhere in the first third of these conditionals we encounter ones in which the degree of truth of the antecedent is slightly higher than the degree of truth of the consequent. These premises are not wholly true, so the argument is unsound.

If this is a reasonable resolution of the paradox of tallness, how does it carry over to (4)? There are two different ways in which the transfer might be done, according to whether or not we wish to retain the standard method of modeling possible situations described earlier, which is to begin with a stock of objects whose possibilities we wish to model, and to construct possible situations by selecting some of the objects and configuring them with atomic properties and relations. If we retain this approach, another of its constituents which we can employ is that of the *relative possibility* relation between different possible situations. To use Nathan Salmon's terminology, each self-contained configuration of objects with properties and relations can be regarded as a *way* for those objects to *be* (Salmon, 1989: what follows is my own perspective on the approach of Salmon, 1986, which is not necessarily one with which he would agree). So we might have three possible situations, w, u, and v, where it is part of w that x and $p_1, \ldots, p_{20}$ stand in the "made of" relation, part of u that x and $p_1, \ldots, p_{11}, p_{32}, \ldots, p_{40}$ stand in the "made of" relation, and part of v that x and $p_1, \ldots, p_{10}, p_{31}, \ldots, p_{40}$ stand in the "made of" relation. This gives us three different ways for x to be. But on top of this, we have to say which ways for x to be are possible relative to the various other possible situations, and this is a question which we can treat as a matter of degree. Relative to u, v has a high degree of possibility, indeed is perhaps *entirely* possible, since there is only a difference of one part in the make-ups of x in u and v. But relative to w, v can be stipulated to be not possible at all, while again relative to w, u may be regarded as a very remote possibility, though slightly more possible than v, because there is less difference in x. A possibility statement is read as asserting possibility relative to the actual world, so looking at (4) in this

light, we construe it as saying that if a situation in which x has such-and-such a make-up is possible relative to the actual world, so is a situation in which x has a slightly different make-up. But analogously to the case of people of different heights, it is possible to choose two make-ups for x such that x's having the second makes any situation which includes that as a way for x to be more remote from actuality than a situation which includes x's having the first needs to be. Repeated applications of (4), then, essentially involve reasoning through a chain of conditionals, each conditional of the form "if such-and-such is possible for x then so is such-and-such," in which the antecedent can have a degree of truth that is slightly higher than that of the consequent, because the antecedent mentions something that is more possible for x, relative to the way things actually are, than the consequent does. Such a gap prevents the premises which manifest it from being wholly true, so an argument that depends on (4) in this way is unsound.

An alternative way of implementing the degree-of-truth idea is to use the counterpart-theoretic approach to the modeling of possibilities due to Lewis (1968; 1986, ch. 1). To model possibilities for a collection of objects $a_1, \ldots, a_n$ one does not configure those objects with properties and relations, but rather, for each self-contained possibility for $a_1, \ldots, a_n$ which one wishes to model, one selects objects $b_1, \ldots, b_q$ to be the counterparts or representatives of $a_1, \ldots, a_n$ in the model, and then configures those counterparts with properties and relations. Its being possible for a to be f is then modeled by a setup in which a has a counterpart b configured so that f is true of it (that is, of b).

This approach introduces certain degrees of freedom missing in the standard approach. For example, one of the a_i may have two or more representatives $b_{i1}, \ldots, b_{ij}$. Or two of the a_i may have the *same* counterpart b_j (thus, on this approach, we can make sense of the idea that actually distinct things could have been identical). However, more to the point in the present context is the fact that it makes good sense to treat the counterpart relation as a relation of degree. Repeating our previous example in the present context, we would have three possible situations, w, u, and v, such that it is part of w that x and $p_1, \ldots, p_{20}$ stand in the "made of" relation, part of u that a counterpart y of x and counterparts of $p_1, \ldots, p_{11}, p_{32}, \ldots, p_{40}$ stand in the "made of" relation, and part of v that a counterpart z of x and counterparts of $p_1, \ldots, p_{10}, p_{31}, \ldots, p_{40}$ stand in the "made of" relation. But while y and z can be counterparts of each other to the maximum degree, x can only be represented by either to a much lesser degree, because of the great difference in make-up. Still, y can qualify as a slightly stronger counterpart of x than z is, because y has more than half its parts in common with x while z only has half in common.

Returning to (4), we now read it as asserting that if there is a world where a counterpart of x has such-and-such a make-up, then there is a world where a counterpart of x has a slightly different make-up. Definition (4) generates such conditionals as

(8) If it is possible for x to be made of $p_1, \ldots, p_{11}, p_{32}, \ldots, p_{40}$, then it is possible for x to be made of $p_1, \ldots, p_{10}, p_{31}, \ldots, p_{40}$

which we interpret counterpart-theoretically as

(9) If there is a world where x has a counterpart made of (counterparts of) $p_1, \ldots, p_{11}, p_{32}, \ldots, p_{40}$, then there is a world where x has a counterpart made of (counterparts of) $p_1, \ldots, p_{10}, p_{31}, \ldots, p_{40}$.

But (9) has an antecedent "there is a world where x has a counterpart made of (counterparts of) $p_1, \ldots, p_{11}, p_{32}, \ldots, p_{40}$," which has a higher degree of truth than its consequent, "there is a world where x has a counterpart made of (counterparts of) $p_1, \ldots, p_{10}, p_{31}, \ldots, p_{40}$," because of the higher degree of counterparthood associated with the constitution closer to that of x. Again, therefore, the argument against the sufficiency of intrinsic and spatio-temporal duplication for identity that (4) seemed to support is shown to be unsound. Being a universal statement, (4) itself cannot be any more true than the least true of its instances. So on both the counterpart-theoretic and the relative possibility accounts, (4) comes out as at best slightly less than wholly true.

In passing, let us note that this apparatus solves the problem with which we ended §2, the problem of how to make sense of the idea that an individual's natural essence might be vague. In the jargon of the counterpart-theoretic approach, we can understand the claim that it is part of the natural essence of x to be made of a *substantial proportion of* $p_1, \ldots, p_{20}$ as allowing that an object y which at another world w is made of counterparts of a substantial proportion of $p_1, \ldots, p_{20}$ can be fully a counterpart of x, while an object z not meeting this condition cannot (the vagueness of individual essence can also be accommodated by the relative possibility approach). Naturally, the solution generalizes to other respects in which things could have differed from the way they actually are to various degrees. For example, the previous considerations can be repeated with respect to the design of an artifact.

It is not appropriate here to attempt to adjudicate between the relative possibility and counterpart-theoretic diagnoses of the flaw in modal slippery-slope arguments, since this would take us rather far afield into some of the technical esoterica of modal logic and metaphysics (see Ramachandran, 1989). The point is simply that on both accounts, the argument against duplication as sufficient for identity is plausibly convicted of the same fallaciousness as affects the better-known sorites paradoxes which do not involve modality. Thus, while we have not gone beyond intuition ourselves yet in defense of the sufficiency of duplication for identity across worlds, at least we have shown that the intuition is consistent with others that also have some force.

A different kind of objection to intrinsic and spatio-temporal duplication as sufficient for identity has been given by T. J. McKay (1986). McKay's example is a direct counterexample to the sufficiency condition that does not rely on any explicit supplementary argumentation for its force. Suppose we have an organism o_1 arising from a cell c. Then, even though highly improbable, it is conceivable that one way or another the molecules composing c should eventually detach themselves from o_1 and reassemble to constitute a cell c' in which the same molecules are configured in the same way as in c. We shall suppose that $c' = c$, since if this is denied, c' and c may themselves be used in a McKay-style counterexample to the sufficiency of intrinsic and spatio-temporal duplication for identity across worlds. So in this story, what happens is that c reassembles.

But if c reassembles having given rise to o_1, we may suppose that c now gives rise to an organism o_2 by the same biological processes through which it gave rise to o_1. And so long as it does this while o_1 still exists, there is no doubt that $o_1 \neq o_2$. Indeed, logically we can have this phenomenon repeating itself as rapidly as we like to give as many organisms as we like, but two suffice to make the point. Organisms o_1 and o_2 are otherwise unexceptional, and so they both have the usual mundane range of possibilities open to them, concerning when they come into existence, what routes they trace through space, what food they ingest, what fate ultimately befalls them, and so on. Indeed, for any life which o_1 might have had, it seems

that o_2 might have had the same life. Only possibilities which somehow involve one of the o_i rather than the other would be unshareable (for example, o_1 can exist in a world where o_2 does not exist, but o_2 cannot exist in such a world). However, if that is as much as the modal differences between the two amount to, then there are worlds *u* and *v* such that in *u*, o_1 leads such-and-such a life, and neither o_2 nor anything else originating from *c* exists; while in *v*, o_2 leads the same life, while neither o_1 nor anything else originating from *c* exists. Since there need be no other differences in context, it seems that the only required difference between *u* and *v* is in the mere identity of a certain organism. Thus, as it is in *u*, o_1 is intrinsically and spatio-temporally indistinguishable from o_2 as the latter is in *v*. But o_1 and o_2 are different things, hence the counter-example to the sufficiency of intrinsic and spatio-temporal duplication for identity across worlds.

The case has undeniable force. If we can correctly say "*this* one might have been thus-and-so" pointing at o_1, why cannot we equally well say "*that* one might also have been thus-and-so," pointing at o_2, when it is perfectly ordinary possibilities for organisms which fill out the "thus-and-so"? On the other hand, the idea that there are such worlds as *u* and *v* has the counter-intuitive consequence that the normal biological creation processes by which an o_i comes into existence do not settle *which* of the o_i it is which is coming into existence: some extra ingredient, the identity of the organism itself, remains to be added. In a well-known paper on personal identity, Chisholm propounded the view that if functionally equivalent hemispheres of a human brain were transplanted into separate bodies in such a way that no relation not presupposing identity distinguishes one of the new individuals from the other in terms of how he stands to the original owner of the brain ("Oldman"), there might nevertheless be a fact of the matter to the effect that one rather than the other of the new individuals is identical to Oldman (Chisholm, 1970). Since Chisholm is not positing anything like Cartesian substance, the idea that such an identity may hold in the absence of any distinguishing feature of the sort normally taken to be relevant to identity is difficult to understand. Similarly, confronted with o_1 and o_2, the idea that one rather than the other of these is identical to an organism which could have come into existence had things been thus-and-so is equally puzzling. To be able to point at o_1 and o_2 and intone "there could have been an organism which is thus-and-so and is identical to *this* organism, not that one" makes the consequences no more intelligible than they are in Chisholm's case if we point at one of the new individuals and say "*This* one, not *that* one, was Oldman."

However, a significant difference between the modal case and the split-brain case is that in the former there is an inevitable asymmetry to which appeal can be made to justify exclusion of *v*. For in the actual world, o_2 is the second organism to originate from *c*, while in *v* it is the first, since it is stipulated to be the only organism which develops in *v* from *c*. The untoward consequences of admitting *v* may then be taken as an argument for its being *essential* to o_2 to be the second organism to originate from *c* rather than the first, or a later one, and *essential* to o_1 to be the first. We will call this the *essentiality of order*. Then if we count the fact that o_2 is the second to originate from *c* as being intrinsic to o_2, we can still have intrinsic and spatio-temporal duplication across worlds as a sufficient condition for identity.

"Intrinsic" is a term of art, and we are free to extend it in this way, but only if we apply it consistently, counting other properties relevantly like *being the second organism to develop from c* as intrinsic too. Yet earlier, we defended the essentiality of origin in part by pointing out that some forms of skepticism about it allow the identity of an organism which develops from a certain cell at a world to turn on whether or not some *other* cell gives rise to an

organism at that world. So we do not want to say that being in a world where such-and-such another cell does not give rise to an organism is intrinsic to a given organism. How, then, is it any better to allow the identity of an organism which develops from *c* at a world to turn on whether or not *c* has *already* given rise to an organism at that world?

There are two respects in which the cases differ. First, the proposal to allow the identity of the organism which develops from c_1 at *w* to turn on whether any organism develops from c_2 at *w* has consequences that the essentiality of order does not. The main one is that in *w*, on the former proposal, future facts play a role in fixing the identity of presently existing organisms, that is, facts about whether or not c_2 will give rise to an organism. And this seems wrong. Still, this only means that allowing the identity of an organism which develops from *c* to turn on whether it is the first, second, third, and so on to do so is not vulnerable to one particular objection; it does not make the classification of the order-property as intrinsic any more reasonable. However, on the positive side, we can note that there is a particularly intimate relationship between an organism and the cell from which it develops. The two cannot be said to be identical, since the cell ceases to exist when it divides while the organism is just beginning its existence. But there is another relation, variously known as temporary identity, or *coincidence*, or realization, which characterizes how the cell and the organism to which it gives rise stand to each other (Yablo, 1987). If having been coincident with a certain cell is an intrinsic feature of an organism at all, it seems a reasonable extension of the notion of intrinsicness to say that having been identical with a new, or an n-times-used, cell, is also intrinsic.

A move like this is partly terminological, designed mainly to keep the formulation of the sufficient condition for transworld identity simple: intrinsic and spatio-temporal duplication. The substantial issue is whether counting the order property as essential is justifiable; for if it is not, then arguments for the essentiality of a set's members, or an artifact's composition, or an organism's origin, are in trouble, since these apparently depend on constraints on identity that McKay's example, if conceded, would show to be incorrect. Yet these essentialist theses also have intuitive force. So there is an unavoidable trade-off here, unless we find a different way of justifying the essentialist theses.

4 The Grounds of Metaphysical Necessity

Perhaps the most difficult question surrounding the topic of essentialism is the problem of how the kinds of necessities we have been discussing arise. It seems, on the face of it, that these necessities require us completely to rethink our received notions about the grounds of necessity. According to the traditional view, which receives its paradigm formulation in Hume's writings, there are no "necessary connections" between distinct existences. But this is inconsistent with a thesis such as the essentiality of origin, which postulates a connection between an organism and the cell from which it arose that is necessary *modulo* existence of the two entities. On the positive side, according to Hume, whatever necessities there are, are to be explained in terms of "relations of ideas." But again, this is inconsistent with such a thesis as that Wiggins is essentially human: even if a name such as "Wiggins" has a meaning, grasp of which is a condition for mastery of the name, it is not plausible that "human" would be part of the meaning of a name of a human. For example, in a society with advanced robotic or biotechnology, one might have complete mastery of an individual's name without knowing whether or not that individual is human. And it is completely implausible that

some way of identifying the cell from which a named organism develops should be part of the content of any name of that organism. The overall problem for the traditional view is that the sorts of examples we have been discussing involve necessary truths which are *a posteriori*, while truths that are based on relations of ideas are supposed to be *a priori*.

However, our discussion in fact contains an implicit defense of the traditional association between the necessary and the *a priori*. For any specific essentialist thesis about a particular entity or entities, such as that Wiggins is human, is derived from two premises, one of which gives some *a posteriori* information about the relevant object or objects (such as that Wiggins *is* human) and the other of which states a modal principle to which objects of that sort must conform, such as the principle that the biological kind of an organism is essential to it. And the latter principle is *a priori* true if it is true at all. So the source of necessity may be in "relations of ideas" after all. This division of labor in the production of the necessary *a posteriori* renders essential properties a little less mysterious. The explanation of why some property of an object is temporary, or permanent, may have to do with the physical nature of the environment in which the object is situated, or with other physical features of the object; and it is hard to see how the explanation of why a property is accidental rather than essential or vice versa could make headway from similar resources. But it will not have to, if the status of a property as accidental or essential is settled by *a priori* principles.

On the other hand, for every alleged *a priori* truth which our defenses of certain essentialist theses have appealed to, there is a good question about the source of the truth of that principle. It would be convenient if the duplication-implies-identity principle or the no-bare-particulars principle could be accounted for as the product of definitions or decisions ("conventions"). But it is unsatisfactory to suppose that these truths are manufactured by stipulations, whether explicit or implicit. To the extent that one finds the principles plausible, they seem forced on us by the nature of our concepts. At this point, it looks as if the best one could hope for is a Strawsonian "descriptive metaphysics" which spells out the aspects of our concepts that account for the force of the principles.

It is surely no accident that essentialist theses are asserted for unified classes of things. We do not find any grounds for holding that there are *some* sets whose members belong to them accidentally, while others have their members essentially, or *some* organisms whose origin is essential to them and others whose origin is accidental. A hypothesis which would explain this is that we have a general conception of what a set is, or what an organism is, and the conception of a specific set, or a specific organism, as an instantiation of the general conception. That is, the general conception of a set, or an organism, has certain *parameters*, and our understanding of what is involved in the existence of a particular set, or organism, is simply that these parameters take on particular values: no less, *and* no more, is involved. In more detail, an organism is conceived of as a thing with a particular origin in some reproductive process, a particular nature deriving from the entities involved in that process, and a subsequent career that traces some continuous spatio-temporal path through the world; and any particular organism is simply a particular manner of instantiation of these parameters. There is, of course, no simple step from parameter-instantiation to essential property, as the inclusion of spatio-temporal path here illustrates. The point is, rather, that if there is no more to individuality than instantiation of the parameters of a general conception, then there is no sense to a notion of identity which transcends instantiation of parameters. But it seems that opposition to essentialist theses of the principles on which, we have argued, they rest inevitably leads to such a notion of identity. For example, on McKay's view,

the parameters of the general conception of organism may be instantiated at a world without this being sufficient to fix which organism it is that results from the instantiations. And on a view that denies that the kind of a thing is essential to it, we arrive at a notion of bare particular, a thing which has a specific identity without, it seems, instantiating the parameters of any general conception at all.

The proposed scheme, then, if it is an accurate reflection of our concepts, offers some justification for some essentialist theses. What other kinds of justification are there? In §1 of this chapter, we noted some technical difficulties in getting the definitions of "essential property" and "individual essence" exactly right. Fine has suggested that these problems are symptomatic of a deeper inadequacy in an approach to these concepts which tries to explain them in terms of what is possible and what is necessary (Fine, 1994). According to Fine, a truth of the form "P is essential to x" will certainly give rise to modal truths, such as that necessarily, if x exists then x has P. But simply because facts about what is essential give rise to such truths, it does not follow that essentialist concepts are modally explicable. And in fact they are not, he argues, since it is possible for the same range of modal facts to be determined by different, incompatible, collections of essentialist facts. For example, at least three competing views of the essentialist facts about persons, bodies, and minds might give rise to the same range of modal facts, the three views disagreeing over how a person, her body, and her mind are related. If a person p has a body b and a mind m, it may be true that, necessarily, if p exists p has b and m; but one philosopher might say that this is because persons are fundamental, though essentially possessing the bodies and minds they do, while another might say that this is because human bodies are fundamental, giving rise to persons when they (the bodies) realize sentience, but giving rise to the same mind and therefore the same person in any possible situation where they give rise to a mind. What this brings out, Fine says, is that an essentialist truth has its source in specific objects, but the modal truths to which essentialist truths give rise do not determine which particular objects are the sources of the essentialist truths.

What Fine is suggesting, then, is that modal concepts are insensitive to essentialist facts in much the same way as they are to intensional facts. It is familiar that analogs of intensional notions like proposition and belief can be defined in modal terms, using the possible-worlds apparatus; but if these analogs are taken to be the intensional notions themselves, there are various counter-intuitive consequences, such as that everyone believes all the logical consequences of their beliefs, and that there is only one necessarily true proposition. In a similar way, our definition (3), for example, has the consequence that an object can have more than one individual essence.

In place of the modal approach, Fine would put the Lockean (or Aristotelian) idea of *real definition* in center stage for the explanation of essentialist concepts. We commonly think that it is words, or concepts, which admit of definition; but if we can make sense of ordinary things being definable as well, then the individual essence of a thing would be exactly what that thing's definition delivers. Correspondingly, essential properties would be those which flow from individual essence, and there would be no reason to expect existence, or being a member of $\{x\}$, to be essential to an ordinary material object x. With these ideas worked out in detail, we have a rival to the modal approach, and the project of resolving the problems with the modal definitions, if they can be resolved, takes on more urgency. So despite the fact that investigation of essence stretches back at least to Aristotle, we can expect lively and ongoing research to extend it; it is yet another subject whose history is definitely not at an end.

Postscript

PENELOPE MACKIE

In the main text, it is pointed out that two theses about the essential properties of individuals seem intuitively very plausible: the thesis – known as the essentiality (or necessity) of origin – that individuals such as organisms and artifacts have certain particular features of their origins essentially, and the thesis that the broad kind to which something belongs is essential to it. As is also pointed out in the text, it is one thing to find such theses intuitively

plausible, and another to discover principles that explain why certain properties are essential properties. This postscript explores some of these issues in more detail.

The Essentiality of Origin and Individual Essences

The argument given in the text for the essentiality of origin is primarily an argument for what I shall call *substantial individual essences* – individual essences that consist in intrinsic features of a thing other than the property of identity with that thing. A substantial individual essence would thus provide a non-trivial answer to the question what *makes* something the particular object that it is – what being that particular object consists in. In the main text it is argued that, if things such as organisms and artifacts have substantial individual essences, they include certain unique features of the way those things originated, thus supporting a version of the essentiality of origin (§2).

As indicated in §1, a thing's individual essence may be defined as a property, or set of properties, that is necessarily both necessary and sufficient for being that thing. (According to the characterization (3) in §1, if e is an individual essence of x, then x has e essentially, and anything, in any possible world, that has e is identical with x. But if anything in any possible world that has e is identical with x, having e is necessarily sufficient for being x.)

The "sufficiency" aspect of an individual essence has important implications. If an object has a substantial individual essence, its essential properties must include at least one that is immune to duplication: a property that is "unshareable" in the sense that it cannot be possessed by two objects in any possible world. Unless the set includes such a property, possession of the set of properties cannot, strictly, be sufficient for identity with the individual in question. In the text, it is suggested that if certain unique features of the way that a particular thing originated are essential to it, this demand for "unshareable essential properties" can be met. Hence this individual-essence-based argument may be regarded as a version of a "sufficiency" argument for origin essentialism (Robertson and Atkins, 2013).

In the main text, it is argued that substantial individual essences are required to rule out the possibility of duplication without identity – more precisely, to rule out there being pairs of possible worlds containing objects that are intrinsic and spatio-temporal duplicates and yet numerically distinct. Thus the argument for substantial individual essences, and hence the associated argument for origin essentialism, depends crucially on the assumption that such duplication without identity is unacceptable. As is noted, however, this assumption may be questioned.

One ground for questioning it (§3) is a variant of Chisholm's paradox: an argument that appears to lead, from the apparently uncontroversial assumption that a thing's origin could have been slightly different from the way that it actually was, to the conclusion (via the transitivity of identity) that there may be two possible worlds containing entities that are distinct although they are intrinsic and spatio-temporal duplicates. As is pointed out in the text, however, suspicion is cast on the soundness of this argument by its similarity to a standard sorites paradox of vagueness. It is therefore plausible to suppose that there is some flaw in the Chisholm's paradox argument, and several diagnoses are explored in the main text. Moreover, as noted there, diagnosing a flaw in the Chisholm's paradox reasoning is of significance for the justification of origin essentialism independently of the defense of the "no duplication without identity" principle. For the only intuitively plausible versions of the essentiality of origin combine the view that an artifact (such as a watch, say) could *not* have

come into existence from completely different matter with the concession that the artifact *could* have come into existence from slightly different matter. The Chisholm's paradox reasoning, if sound, would show that this combination of "modal restriction" with "modal tolerance" is incoherent.

As is acknowledged in the main text, however, blocking the Chisholm's paradox argument does not solve all the problems for the individual-essence-based approach to origin essentialism. A second reason for questioning the crucial prohibition on duplication without identity has its roots in a problem, identified by McKay (1986), that has become known as the "recycling problem." McKay's argument shows that a property such as *being an organism of kind K that develops from cell c*, even if it is in fact possessed by only one organism, and even if it is an essential property of that organism, cannot be a sufficient condition for identity with that organism. For as long as *c* could be "recycled" (to produce a second organism of kind *K* at a later time), the property could be duplicated – in the sense of being instantiated by more than one thing in a single possible world. Such a "recycling world" is not itself a counter-example to the "no duplication without identity" principle, since the two organisms in the recycling world have, in that world, different spatio-temporal properties. But unless there is some difference in the *essential* properties of the two organisms, there can be possible worlds that differ only in that one of them contains one of the organisms, whereas the other contains the other, in conflict with the "no duplication without identity" principle (§3).

The response proposed in the text to the recycling problem is to protect the view that persisting things such as organisms have substantial individual essences – and the associated "no duplication without identity" principle – by adding a principle of the *essentiality of order*. Evidently, if it is essential to an organism o_1 – a particular tree, say – that it is not only a tree that develops from cell *c*, but also the *first* tree that develops from *c*, then the tree has, after all, an essential property that is immune to duplication, and distinguishes it, in any possible world, from any other tree that develops from cell *c*.

However, this solution comes at a price. For one thing (as noted in the main text) it is not obvious that a property such as being the first organism of its kind to develop from cell *c* is an intrinsic property. Second, a conception of individual essences that incorporates the essentiality of order appears to have counter-intuitive consequences. For example, if it is not only necessary, but also (necessarily) sufficient, for identity with an organism that was in fact the only tree to originate from cell *c*, to be the *first* tree to originate from cell *c*, then in a "recycling" world in which *c* generates a tree in the year 1500, and a second tree in the year 2010, the first tree, and not the second, must be identified with the original tree, even if the 2010 tree in the recycling world is otherwise an exact duplicate of the actual tree in every respect, including the time of its origin (cf. Hawthorne and Gendler, 2000; Forbes, 2002).

Such difficulties do not refute the individual-essence-based argument for the essentiality of origin. Nevertheless, they are serious enough to cast some doubt on the thesis that persisting things really do have substantial individual essences, and on any argument for origin essentialism that requires this assumption.

Faced with this problem, one might seek to defend origin essentialism without appealing to individual essences. One initially attractive line of thought is prompted by the observation that, when we consider ways in which persisting individuals could have been different, we typically focus on ways in which they could have *become* different. If *every* possibility for an actual individual such as an organism or an artifact has to be a way that it could have

developed from the way that it actually was at some time in its existence, then no such individual could have had a different origin. For once it has come into existence, it is, of course, too late for it to acquire a different origin. However, this line of argument is highly problematic as a defense of the essentiality of origin thesis. It seems that it would prove far too much, since it would imply that an individual could not have had an origin different in any respect (even, for example, in its location) from its actual origin.

These and other difficulties have led some to conclude that there is no coherent justification for the essentiality of origin thesis, even if it may be possible to explain its intuitive appeal (Mackie, 2006, ch. 6). A further suggestion, made by David Lewis, is that the kernel of truth in the thesis is simply that in some contexts of counterfactual speculation about a thing it is appropriate to keep fixed certain features of its origin (1986, p. 252). Yet others have attempted to provide novel arguments for the thesis (Rohrbaugh and deRosset, 2004, and, for discussion, Cameron and Roca, 2006, and Forbes and Robertson, 2006). In spite of extensive discussion over several decades, there is no consensus on the status of the undeniably appealing, yet extremely perplexing, thesis of the essentiality of origin.

Finally, if things such as persons, organisms, and artifacts do not have substantial individual essences, what does their individuality consist in: what, for example, is it that makes Socrates the individual that he is and no other? One answer that has been proposed is that it is the possession of a *haecceity* – a *sui generis* non-qualitative essential property that is unique to the individual. Another answer is that there is *nothing* that makes Socrates the individual that he is, if what is at issue is whether there is any essential property that is non-trivially sufficient for identity with Socrates (Mackie, 2006). Rather confusingly, both views are referred to in the literature as varieties of "haecceitism" (see Mackie and Jago, 2013, §4).

The Essentiality of Kind Membership

Even if the view that ordinary individuals have substantial individual essences or essential origin properties cannot, in the end, be sustained, that would, of course, leave unscathed the second type of essentialism mentioned in the main text, according to which things belong essentially to certain sorts or kinds. However, it is one thing to say that the broad kind to which a thing belongs is an essential feature of it, and another to decide which are the "essential kinds."

One relatively modest thesis is that everything belongs essentially to some general ontological category, such as *substance*, *event*, *property*, and so on. This "category essentialism" would apparently explain why David Wiggins could not have been a musical performance, for example. If, however, what is sought is an explanation (or justification) of claims such as the claim that Wiggins could not have been a lake or a polar bear or a forest, or that a pot of marmalade could not have been a railway station (§2), evidently some more restrictive notion of essential kinds is required.

A popular idea is to invoke the notion, which has its roots in Aristotle's theory of essence and accident, of a *substance sortal* (or *substance concept*). A substance sortal is a concept that plays a special role in individuation: it not only provides a criterion of identity, but also represents a "necessarily permanent" property: one that applies to an object throughout its existence if it applies to it at any time in its existence, and hence is a property that the object cannot lose without ceasing to exist (Wiggins, 1980, ch. 3; 2001, ch. 3). According to this criterion, it is plausible to regard *cat* as a substance sortal (nothing can change from being a

cat to not being a cat, or vice versa, without going out of existence), although *kitten*, while evidently in some sense an individuative concept, is not a substance sortal.

However, it is one thing to say that an object cannot change from being a cat to not being a cat, or vice versa, without going out of existence, and another to say that an object that is a cat could not have existed without ever being a cat. Being a necessarily permanent property does not entail being an essential property, as is demonstrated by properties such as *originating in Paris*, or *being at all times unmarried*.

In response, some defenders of a "sortal-based" account of essential kinds will argue, as E. J. Lowe has done, that, in the case of substance sortal properties, the reason *why* the property is necessarily permanent is that it is also an essential property. For example, if the cat Tibbles cannot cease to be cat without ceasing to exist, perhaps the reason is that "a cat" specifies *what Tibbles is*, in a sense that implies that *being a cat* is at least part of her essence (Lowe, 2007). According to this argument, all substance sortals would represent essential properties.

A different way of developing a sortal-based account of essential kinds is suggested by David Wiggins, who argues that it is only *ultimate sortals* that represent essential properties, where an ultimate sortal is the most general sortal corresponding to a given principle of individuation (Wiggins, 1980; 2001). Since, on Wiggins's theory, two substance sortals may provide the same principle of individuation, this version of a sortal-based account of essential kinds yields different – and conflicting – results from those implied by Lowe's proposal.

Essential Properties and What a Thing Is

It is worth noting that the proposal just considered – that the Aristotelian notion of a substance sortal is the key to understanding which kind properties are essential – has clear affinities with Fine's (1994) suggestion that the notion of essential property that is of interest to metaphysics is tied to the notion of a thing's nature as revealed by a real definition that says "what the thing is." It is a further, interesting, question whether (as is suggested in the main text) a conception of essence in terms of real definition requires that everything has a unique real definition (and thus has either its own substantial individual essence or its own haecceity), or whether, for example, the real definition of Socrates might be the very same as the real definition of Plato.

It can also be noted that although Fine's proposed counter-examples to the standard (modal) conception of essence in terms of necessary properties (and his associated claim that the modal conception goes wrong in including, among a thing's essential properties, necessary properties of the thing that do not flow from its nature or essence) have been widely accepted, not all have agreed with Fine in drawing the moral that metaphysical modality should be understood in terms of a prior notion of essence. In particular, there have been attempts to provide a revised modal theory of essence that characterizes a thing's essential properties as a proper subset of its necessary properties demarcated by a restriction that does not treat the notion of nature or essence as primitive or fundamental (Cowling, 2013; Wildman, 2013; and, for discussion, Skiles, 2015).

Altogether, then, questions about the ultimate source of essential properties, and about what essential properties things have, remain live issues that are the subject of ongoing and unresolved debate.

Reference and Necessity

ROBERT STALNAKER

Saul Kripke remarked, at the beginning of his lectures, *Naming and Necessity* (1980), that he hoped his audience would see some connection between the two topics mentioned in his title. In those lectures Kripke defended some bold theses, some about naming that belong to semantics and the philosophy of language, others about necessity that belong to metaphysics. It is clear that the arguments for the different theses were interrelated, but it remains a matter of debate just what the connections are, both in Kripke's argumentative strategy, and in the issues themselves. Kripke and Hilary Putnam were criticized for attempting to derive metaphysical conclusions – about the essential properties of things – from premises in the philosophy of language about the nature of reference and the semantics of proper names. One might instead think that the direction of Kripke's arguments go the other way: that conclusions about reference and proper names were derived in part from controversial metaphysical assumptions about possible worlds and essential properties. Either way, there is reason to be puzzled: on the one hand, one might be skeptical (to borrow the metaphor that Nathan Salmon used to express his puzzlement about this) that one could, without sleight of hand, pull a metaphysical rabbit out of a linguistic hat (see Salmon, 1981). On the other hand, one might wonder why a proper understanding of the way our language happens to work should require controversial assumptions about the metaphysical nature of the world that our language talks about. My aim in this chapter is to try to resolve some of this puzzlement by clarifying the relationship between theses and questions about reference and theses and questions about necessity and possibility. In the background of my discussion will be very general questions concerning how claims about the way we talk about the world relate to claims about what the world must be like, but in the foreground will be more specific questions concerning the relations between the different theses Kripke defends about individuals and their names. My main claim will be that Kripke's contribution was not to connect metaphysical and semantic issues, but to separate them: to provide a context in which questions about essences of things could be posed independently of assumptions about the semantic rules for the expressions used to refer to the things, and in which

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

questions about how names refer could be addressed without making assumptions about the nature of the things referred to. I will argue that Kripke's theses about proper names and reference do not presuppose any metaphysical theses that ought to be controversial, though even stating those theses requires a framework that might be thought not to be metaphysically neutral. And I will argue that no metaphysical conclusions are derived from theses about reference and names, although clarification of the nature of reference helps in the rebuttals to arguments against metaphysical theses that Kripke defends.

I will start in §1 by contrasting three kinds of questions that Kripke discusses in *Naming and Necessity* – two that belong to semantics and the philosophy of language, and one that belongs to metaphysics – and sketching the answers that Kripke defends, along with contrasting answers that he criticizes. Then, in §2, I will discuss the apparatus that he uses to clarify his questions – the possible-worlds framework – and argue that it should be understood not as a metaphysical theory, but as a methodological framework in which alternative metaphysical and semantic theses can be stated. In §§3–5 I will look in more detail at the arguments for the different theses and the way the three different kinds of issues interact. (See also Chapter 34, ESSENTIALISM; Chapter 36, NAMES AND RIGID DESIGNATION; and Chapter 31, MODALITY.)

1 Questions and Theses

At this point my aim is just to set the stage by making some simple distinctions between questions, and stating, without much explanation or argument, some alternative answers to the questions. First there are questions of what I will call "descriptive semantics." A descriptive-semantic theory is a theory that says what the semantics for the language is, without saying what it is about the practice of using that language that explains why that semantics is the right one. A descriptive-semantic theory assigns *semantic values* to the expressions of the language, and explains how the semantic values of the complex expressions are a function of the semantic values of their parts. The term 'semantic value,' as I am using it, is a general and neutral term for whatever it is that a semantic theory associates with the expressions of the language it interprets: the things that, according to the semantics, provide the interpretations of simple expressions, and are the arguments and values of the functions defined by the compositional rules that interpret the complex expressions. If, for example, the semantic theory in question assigns senses or intensions to the names and predicates of a language, and explains the senses of complex expressions as a function of the senses or intensions of their parts, then as I am using the term, the semantic values of that semantic theory will be the senses or intensions. The particular descriptive semantic question we will be concerned with is the question, what kind of thing is the semantic value of a proper name?

Second, there are questions, which I will call questions of 'foundational semantics,' about what the facts are that give expressions their semantic values, or more generally, about what makes it the case that the language spoken by a particular individual or community has a particular descriptive semantics. The specific question of this kind that we will focus on is the question, what is it about the situation, behavior, or mental states of a speaker that makes it the case that a particular proper name, as used by that speaker in a particular linguistic community, has the semantic value that it has? (See also Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING, §2; Chapter 8, A GUIDE TO NATURALIZING SEMANTICS.)

Third, there are questions about the capacities and potentialities of the things in the domain forming the subject-matter of some language; what, for example, might have been true of the things, such as persons and physical objects, that are the referents of some particular proper names?

Kripke's answer to the first question – the descriptive-semantic question about proper names – is the Millian answer: the semantic value of a name is simply its referent. The contrasting answer that he argued against is that the semantic value of a name is a general concept that mediates between a name and its referent: a concept of the kind that might be expressed by a definite description. According to this contrasting answer, the semantic value of the name – its sense or connotation – determines a referent for the name as a function of the facts: the referent, if there is one, is the unique individual that fits the concept, or perhaps the individual that best fits the concept.

Kripke's answer to the second question – the foundational-semantic question – is that a name has the referent that it has in virtue of a causal connection of a particular kind between the use of the name and the referent; the referent is the individual that plays the right role in the causal explanation of the fact that the name is being used, in the particular context in question, in the way that it is being used. In the case of this question, it is less clear what the contrasting thesis is, since the question is not explicitly addressed by the philosophers whom Kripke is criticizing. But what seems to be suggested is that the sense of a name is determined by the abilities and dispositions of the speaker to describe or identify a certain individual.

In response to the question about the capacities and potentialities of the things that we commonly refer to with names, Kripke defends the thesis that it makes sense to talk about the logical potential of an individual thing independently of how it is referred to, and that this potential is greater in certain ways, and less great in others, than some philosophers have supposed. For example, Shakespeare need not have been a playwright; he need not have written anything at all. He might have died in infancy, and been someone of whom we had never heard – even someone of whom all trace was lost after the seventeenth century. He might not have been called "Shakespeare," by us, or by anyone. His plays, or at least plays which are word-for-word just like his plays, really might have been written by someone else of the same name. On the other hand, Shakespeare could not possibly have been anything other than a human being, and he could not possibly have had parents other than the ones that he in fact had. In contrast, others have conceded that Shakespeare might have lacked any one of the attributes commonly attributed to him, but argued that he could not have lacked them all. Attributes not commonly known to apply to Shakespeare, such as having the particular parents that he in fact had, are all attributes that he might have lacked.

One thing I will argue is that while Kripke defends these theses about the descriptive semantics of names, the way the reference relation is determined, and the capacities and dispositions of human beings and physical objects (and I think he makes a persuasive case for each of them), his most important philosophical accomplishment is in the way he posed and clarified the questions, and not in the particular answers that he gave to them. I will suggest that we might buy Kripke's philosophical insights while rejecting all of the theses – while opting for a pure, Russellian description-theory of ordinary names, a non-causal account of the way names get associated with their values, and, in metaphysics, either for an anti-essentialist thesis according to which Shakespeare might have been a lamppost or a fried egg, or for a Leibnizian theory according to which Shakespeare had even his most apparently accidental properties essentially. The positive case for the theses that Kripke

defends is not novel philosophical insight and argument, but naïve common sense. The philosophical work is done by diagnosing equivocations in the philosophical arguments for theses that conflict with naïve common sense, by making the distinctions that remove the obstacles to believing what it seems intuitively most natural to believe.

2 The Possible-Worlds Framework

To accept what I will argue is Kripke's main philosophical contribution, you do have to buy a framework, an apparatus that he used to sharpen and clarify the contrasting theses, both semantic and metaphysical. I won't try to claim that the apparatus is either semantically or metaphysically neutral, but I will argue that the motivation and commitments of the framework are more methodological and conceptual than they are metaphysical. Philosophers often talk as if the decision to theorize with the help of this framework is, if one takes the claims one makes while using it seriously, a specific ontological commitment to a certain kind of entity. Some philosophers reject the framework because they reject the ontological commitment that its serious use makes. One hears, "I don't believe in possible worlds," as one might hear people say that they don't believe in transubstantiation, or flying saucers from other planets (commitments that some philosophers believe are about as plausible as the commitment to possible worlds). I think this attitude is based on a misconception (although I have to concede that it is a misconception that some defenders of possible worlds share with the critics). It is not that it is a misconception to think that serious talk about possibilities commits one to the existence of the possibilities one claims there are, just as it is not a misconception to think that the literal use of quantifiers commits one to the existence of things that one purports to quantify over. But it is not the framework itself that makes the specific commitments, just as it is not the semantics for first-order logic that makes any particular ontological commitment. Suppose someone were to reject the standard (extensional) semantics for first-order logic on the ground that he did not believe in individuals, to which that semantics is ontologically committed. The proper response would be to point out that first-order semantics is a framework for doing ontology, and not a particular thesis about what ontology is correct. Individuals are whatever there is to talk about; the semantic theory itself says nothing about what there is to talk about, and so makes no particular ontological commitments. Quine's slogan "To be is to be the value of a bound variable" is not an ontological thesis, but an attempt to promote a framework in which the ontological commitments of alternative philosophical and scientific theories can be stated without equivocation and compared.

The Leibnizian slogan "Necessity is truth in all possible worlds" should be understood in a similar spirit. This slogan and the possible-worlds framework that it presupposes should, I think, be understood not as an attempt to provide an ontological foundation for a reduction of modal notions, but as an attempt to formulate a theoretical language in which modal discourse can be regimented, its structure revealed, equivocation diagnosed and avoided. Modal discourse – speech that involves words such as "may," "might," and "must" – is notoriously complex and problematic, providing fertile ground for ambiguities, both ambiguities of scope, that arise because the semantic structure of modal statements is complicated and not simply reflected in surface syntax, and ambiguities that arise from alternative senses and context dependence of the modal words. Modal words interact with each other and with quantifiers, descriptions, temporal modifiers, and grammatical tense, aspect,

and mood in complicated ways that are difficult to sort out. Philosophical puzzles about, for example, necessary connection and counterfactual dependence, reference to non-existent things, capacities, and dispositions, the ability to do otherwise, the necessity of the past and the openness of the future, will presumably not all be dissolved simply by getting clear about modal discourse; but everyone should agree that clarifying the discourse in which such problems are posed is an essential first step. It is important to separate disagreements based on contrasting interpretations of the way the language works from those about the claims that the language is being used to state. Whatever one's metaphysical beliefs about the reality that modal discourse purports to describe, one should agree that it would be nice to have a language that is free of some of the ambiguities that infect modal discourse, and in which the claims made with modal words and constructions might be paraphrased; a language that uses only parts of discourse that are relatively clear and uncontroversial (the indicative mood and quantifiers), but that still has the expressive power to make claims about what might, would, or must be true. Achieving such clarification does not require a reductive analysis of modal to non-modal concepts, and so it is not required that a canonical language in which we do modal semantics be built on some pure, non-modal foundation, any more than formal languages designed to clarify quantification needed to be built on some pure, non-quantificational foundation (whatever that would be). What is needed is only the kind of opportunistic departure from ordinary language involved in the boot-strap operation that Quine called "regimentation." In the kind of regimentation Quine recommends, we begin with *ad hoc* paraphrases to remove ambiguity, we introduce variables to facilitate cross-reference, and we adopt a syntax in which quantifier scopes are reflected in a simple and systematic way in the order of the symbols and the placement of parentheses. "The artificial notation of logic," Quine remarked, "is itself explained, of course, in ordinary language" (1960, p. 159). Similarly, the primitive resources of the possible-worlds framework are explained in ordinary modal language, and the explanations will be intelligible only to one who understands at least some of that part of language. A modal skeptic who doubts that anything both meaningful and true is said in modal discourse will doubt both the value and the intelligibility of a framework in which that discourse is clarified. But it may be that the source of the skepticism is in the equivocations and unclarities that the framework helps to remove.

The general strategy is to find a part of our modal discourse that seems relatively free of the particular equivocations and unclarities that infect modal discourse generally, a part that might be developed and used to clarify the rest. We look for a way of making modal claims that uses paraphrases to avoid problematic constructions, a way that uses forms of expression that may perhaps be stilted and less idiomatic than the familiar ones, but that will still be recognizable paraphrases of ordinary modal claims. The following assumption about what is, in any sense, possible points the way to one such strategy of paraphrase: if something might be true, then it might be true in some particular way. It would make no sense to affirm, for example, that there might be life elsewhere in our galaxy, while denying that it is possible that there be life in any particular part of the galaxy, or that there might be life of any particular kind – animal life, or non-animal life – elsewhere in the galaxy. If something is possible, then it is possible that it be realized in a concrete way – perhaps in many alternative ways. The possible-worlds framework begins with this simple assumption, and with the assumption that, in general, statements about what may or might be true can be described in terms of the ways a possibility might be realized. The framework takes alternative specific ways that possibilities might be realized as the primitive elements, out of which propositions – the things that are said to be possible, necessary, or true – are built,

and in terms of which the modal properties of those propositions are defined. The main benefit of this move is that it permits one to paraphrase modal claims in an extensional language that has quantifiers, but no modal auxiliaries, and so in a language in which the semantic structure of the usual modal discourse can be discussed without begging controversial questions about that structure.

I have been arguing for the metaphysical neutrality of the possible-worlds framework: but I should emphasize that I do not mean to suggest that the use of the framework is free of ontological commitment to possibilities (such as ways things might be, counterfactual situations, or possible states of the world). Regimentation clarifies one's commitments, but does not pretend to eliminate them. Furthermore, it must be conceded that the moves made in this regimentation of modal discourse (particularly the move that paraphrases "– might have been true in various particular ways" as "there are various particular ways that – might have been true") are not completely innocent (see Chapter 31, MODALITY, §3.3). As Quine would be the first to emphasize, no strategy of regimentation is neutral in any absolute sense: "The quest of a simplest, clearest overall pattern of canonical notation is not to be distinguished from a quest of ultimate categories, a limning of the most general traits of reality" (Quine, 1960, p. 161). But it is a desideratum of any such project that it be able to accommodate and articulate a range of alternative responses to the questions and puzzles that motivated the project. I think the possible-worlds framework satisfies this desideratum, but the real test of this claim is not in some general methodological argument, but in the fruits of the work that is done with its help.

3 What Are the Semantic Values of Names?

The possible-worlds framework provides the resources to state and clarify both metaphysical and semantic theses. In both cases, I want to argue, the principal conceptual benefit of the apparatus is that it provides an account of a subject-matter that is independent of languages used to describe that subject-matter. Of course, whether the subject is geology or modal metaphysics, we never get away from language – it is just too hard to say very much without using it. But just as we want to distinguish rocks from words (even if we have to use words for rocks to do it), so it is useful to distinguish possibilities from the words used to describe them. To make this distinction is not to beg any questions against the philosophical thesis that the source of all necessity is in language; a conceptual distinction does not foreclose the possibility that one of the things distinguished may in the end be reduced to the other.

To see that possibilities are part of the subject-matter of semantics as well as of modal metaphysics one need only make the following assumptions: First, a central function of an assertion is to convey information, and information is conveyed by distinguishing between possibilities. Second, a principal goal of semantics is to explain how the expressions used to perform speech-acts, such as assertion, are used to convey information – to distinguish between possibilities – and how the way complex sentences distinguish between possibilities is a function of the semantic values of their parts. To understand what is said, for example, in an utterance of "The first dog born at sea was a basset hound," one needs to know what the world would have to be like in order for what was said in that utterance to be true.

These simple assumptions about the goal of semantics might be expressed in terms of truth-conditions: semantics is concerned, among other things, with the truth-conditions of statements, and the way their truth-conditions are a function of the semantic values of their

parts (where semantic values are whatever they must be in order to contribute appropriately to truth-conditions). What are truth-conditions? If we are looking for an answer to this question that identifies a non-linguistic object that semantics can associate with statements, it seems natural to say that the truth-conditions of a statement are the possibilities that, if realized, would make the statement true. We want a conceptual distinction between truth-conditions and any particular forms of expression in which those truth-conditions might be stated, simply because it is useful to theorize about a language in a different language, and when we do so, we want to be able to talk not just about the inter-linguistic relations between the language we are theorizing about and the language we are theorizing in, but about the relation between the language we are theorizing about and the world.

The task of descriptive semantics, in this framework, is to say what kinds of things the semantic values of expressions of various categories are, and to explain how the truth-conditions of sentences (or sentences in context) are a function of the semantic values of their constituents. So to give the semantic value of a proper name is to say what contribution a proper name makes to the truth-conditions of the sentences containing it, where the truth-conditions of a sentence, or a sentence in context, are represented by the set of possibilities that, if realized, would make what the sentence says in that context true. The two answers that Kripke compares – the Millian and the Fregean answers – are made precise in the following ways:

(1) The semantic value of a name is simply its referent; the proposition expressed by a simple sentence containing a name is the proposition that is true in a possible world if and only if that referent has the attribute expressed by the predicate of the sentence.
(2) The semantic value of a name is its sense, which is a concept that applies to, at most, one individual in each possible world (the kind of concept that might be expressed by a definite description). The proposition expressed by a simple sentence containing a name is the proposition that is true in a possible world if and only if the individual to which the concept expressed by the name applies in that world has the attribute expressed by the predicate of the sentence.

Thus far, I have talked only about a question and a framework for clarifying alternative answers to it, and not about arguments in support of one or the other of the answers. The framework is neutral on the question of which of these alternatives, if either, gives a correct account of the semantics of the expressions in English and other natural languages that we identify as proper names. This seems to be an empirical question of no particular philosophical interest, a question that philosophical analysis and argument are not relevant to answering. The way in which the alternative answers are articulated in the framework does point the way to some of the empirical considerations that may be relevant to settling the issue, by making clear what the consequences of those alternatives are; but it appears that no philosophical – certainly no metaphysical – issue hangs on which answer is right. Even though Kripke defended, on empirical grounds, the Millian answer, he nowhere suggested that things had to be this way. For all that he argues to the contrary, we might perfectly well have spoken a language with names that all referred only by having senses that determined referents. It just happens that we do not.

What needed philosophical defense was not the empirical adequacy of the Millian answer, but its coherence. While Kripke did not suggest that philosophical argument could

establish that the answer he favored was correct, he had to answer philosophical arguments that purported to establish that it was incorrect. John Searle, for example, argued that

> the view that there could be a class of logically proper names, i.e. expressions whose very meaning is the object to which they are used to refer, is false. It isn't that there just do not happen to be any such expressions: there could not be any such expressions.… The view that proper names are 'unmeaning marks,' that they have 'denotation' but not 'connotation,' must be at a fundamental level wrong. (Searle, 1969, p. 93)

Michael Dummett makes a similar claim: "there cannot be a proper name whose whole sense consists in its having a certain object as referent, without the sense determining that object as referent in some particular way" (Dummett, 1973, p. 232). These claims are puzzling, in the light of Kripke's way of posing the problem of the descriptive semantics of proper names. It appears that he showed, simply in setting up the alternatives, how to give a coherent specification of a language containing "expressions whose very meaning is the object to which they are used to refer." What kind of argument could show not only that we do not in fact speak such a language, but that we could not possibly do so? To address this question, we need to turn to the second of the two kinds of issues in the philosophy of language that Kripke is concerned with.

4 How Do Names Get Their Semantic Values?

Why do Searle and Dummett think that we could not speak a language of the kind that Kripke described, in which the semantic value of a name is simply its referent? Searle's reason was that "if the utterance of the expressions communicated no descriptive content, then there could be no way of establishing a connection between the expression and the object," no way to answer the question, "What makes *this* expression refer to *that* object?" (Searle, 1969, p. 93). Dummett's reason is similar: "an object cannot be recognized as the referent of a proper name … unless it has first been singled out in some definite way" (Dummett, 1973, p. 232). In both cases, the reason for rejecting the possibility of a certain descriptive semantic thesis appeals to considerations that relate to the foundational question, which asks what it is about the capacities, customs, practices, or mental states of a speaker or community of speakers that makes it the case that an expression has the semantic value that it has. What seems to be suggested is that the hypothesis that a language has a Millian semantics poses a foundational question that cannot be given a satisfactory answer.

But this is not the way either Searle or Dummett put their claims, since they do not separate the two questions, "what is the semantics for names (or the semantic value of a particular name) in the language we speak?" and "what makes it the case that the language we speak (or a particular name in that language) has this semantics?" Once the two questions are separated, it is difficult to see what could rule out the *possibility* that we speak any language that has a well-defined semantics. If a Millian semantics for names can be articulated, why can't a community of speakers adopt the convention to speak such a language?

The assumption implicit in the rejection of the possibility of a Millian semantics is that the two questions we have separated should receive a single answer. Something like a Fregean sense should explain why a name has the particular referent it has, where this is interpreted to mean that it should explain both what it is about the capacities and attitudes

of the speaker that give the name the referent it has, and also what it is that the speaker communicates or conveys in using the name. Kripke charged Frege with conflating these two questions:

> Frege should be criticized for using the term 'sense' in two senses. For he takes the sense of a designator to be its meaning and he also takes it to be the way its reference is determined. Identifying the two, he supposes that both are given by definite descriptions. (Kripke, 1980, p. 59)

Whether Frege is responsible for making this mistake is a question of textual interpretation that I will not comment on, but it is clear, I think, that Searle is concerned with both kinds of questions, and that he takes himself to be following Frege. Searle describes his axiom of identification, a principle that is supposed to be constitutive of singular definite reference, as "a generalization of Frege's dictum that every referring expression must have a sense" (Searle, 1969, p. 80). The principle is about what must be communicated or conveyed (or at least "appealed to" or "invoked") in the utterance of the referring expression; but it is also an attempt to say what it is about the capacities of speakers that explains why their referring expressions have the referents they have. "What I am trying to get at," he says, "is how noises identify objects" (Searle, 1969, p. 83).

If we are implicitly looking for a semantic account of names that answers both questions at once, then the Millian theory that says that the semantic value of a name is simply its referent looks like a non-answer; it seems to be denying the obvious fact that there must be something about the capacities, behavior, or mental state of the users of the name that makes it the case that the name has the referent that it has. On the other hand, the conflation of the two questions masks the fact that the sense theory, interpreted as an answer to the question of descriptive semantics, is also a non-answer to the foundational question. Suppose we were to accept the Fregean thesis that names have the referent that they have because they have a sense that determines a function whose value (at the actual world) is that referent. This simply raises the question: What is it about the capacities, behavior, or mental state of the users of the name that makes it the case that the name has the sense that it in fact has? Whether one is a Fregean or not, the two questions need to be distinguished; and once they are, the way is opened for answers to each that are less easily seen as possible answers to the other: the Millian answer to the descriptive question, and the causal account of reference that Kripke defends as an answer to the foundational question. This latter thesis – that what makes it the case that a name has a certain individual as its referent is that the individual plays a certain role in the causal or historical explanation of the speaker's use of the name – makes no sense as an attempt to specify a semantic value, a candidate to be the meaning or sense of a name, and so it can be taken seriously only after the two questions are distinguished.

Kripke and other defenders of a causal theory of reference were criticized for the vagueness of their thesis. Causal connections are ubiquitous, and it is obvious that there are a great many individuals that are causally implicated in the speaker's use of the name, but that are not by any stretch of the imagination plausible candidates to be the referent. A proper causal theory of reference would have to specify just what sort of causal connection is necessary and sufficient for reference, and that is a notoriously difficult demand. Kripke himself emphasized that he was presenting not a reductive analysis of reference, but only an alternative picture. To some skeptics, this sounded like an evasion. The suspicion was that any sufficiently specific and precise version of the causal theory would be subject

to as many counter-examples as the description theory, and so that the plausibility of the positive alternative to the description theory rested on its lack of specificity. But I think this line of criticism misses the point. What is essential to the alternative picture was the separation of the questions, and the distinction between two different ways in which the extension of an expression might depend on the facts: first, what semantic value an expression has depends on the facts; second, if the semantic value is a sense, the extension of an expression with a given semantic value may depend on the facts. The philosophical work was done in making the distinctions that removed the obstacles to accepting the naïve answers to the questions that were distinguished. If we ask what one has to know to understand a name, the naïve answer is that one must know who or what it names – nothing more. (In contrast, no one would be tempted to give this answer to the analogous question, of what one must know to understand a definite description.) And if we ask how a name comes to name what it names – what, for example, makes "Shakespeare" as we use it a name of the particular person Shakespeare – I think most people would be inclined to point to a historical narrative: his family was called "Shakespeare," or something like that, at the time, and knowledge of him, his plays, and his name were passed down through the generations to us. This is not a particularly exciting philosophical theory, but it doesn't seem wrong, and it does seem incompatible with the kind of answer implied by a description theory. Kripke's causal-chain story is just an articulation of the naive answer, and one that does not add a lot of constructive detail to it. But by separating and clarifying the questions to which these naive answers are answers, he brought out why the theoretical reasons for resisting those answers are bad reasons.

The diagnosis of equivocation is rarely the end of the matter in a philosophical argument. I will sketch a line of argument for the impossibility of a Millian semantics that recognizes the distinction between the two kinds of questions. I don't think this line of argument is successful, but it is instructive to see where it takes the debate.

If there is a credible defense of the thesis that a Millian language is impossible, I think it must challenge the assumption that any well-defined semantics might be the semantics of a language that is used by a speaker, or realized in a speech community. Here is one way that the assumption might be challenged. First, the following seems a reasonable general constraint on the correctness of a claim that a certain semantics is the semantics for the language spoken in a certain community of speakers: if the semantics is correct, then speakers must know, at least for the most part, what, according to the semantics, they are saying. A notion of saying might allow that in some cases one succeeds in saying things using words one does not understand; but it is hard to deny, first, that if one doesn't know what one is saying, then one does not mean what one says, and second, that according to a correct account of what people say in a given speech community, speakers generally mean what they say (not in the sense that they are sincere – believe what they say – but just in the sense that what they say coincides with what they mean).

Second, we may note that it is possible to give a determinate specification of a semantic value without knowing what that value is, even without anyone knowing what the value is. Consider this example discussed by Gareth Evans: let "Julius" be a (rigid) proper name for the person (whoever he or she was) who invented the zip (Evans, 1982, p. 31). Then (assuming that some particular single individual invented the zip) a sentence such as "Julius was born in Minsk" expresses a determinate proposition about a particular individual, but we don't know who the individual is, so we don't know what proposition it is that is expressed. We understand a description of the proposition, and we understand, and may believe, metalinguistic statements about that proposition, such as 'What is said by "Julius was born

in Minsk" is probably false.' We can have beliefs and make assertions about the truth or falsity of whatever proposition is expressed, but (according to this line of argument), we do not thereby assert or believe that Julius was or was not born in Minsk, and we cannot do so unless we know who invented the zip.

Now suppose that one could make a case that our mental relations to particular individuals are in all relevant respects like our relation to Julius – that since we can know individuals only by description, only as whoever or whatever it is that is presented to us in a certain way, we don't ever know, in the relevant sense, who or what it is that we are referring to with the names we use. Then it would seem to follow that, although we can define a language with a Millian semantics, we could never speak one, since we could not have the knowledge required to know what the sentences of such a language say.

I think the first premise of this argument should be conceded: a semantics for the language spoken by a community of speakers cannot be right if it implies that speakers generally do not know what they are saying. It should also be conceded that, according to the Millian semantics for names, as contrasted with the Fregean semantics, speakers do not know what they are saying when they use a name if they do not know who the referent of their name is. But what is it to know what one is referring to? At this point the battleground shifts from semantics and the philosophy of language to the philosophy of mind, where variations on some of the same battles are fought.

Underlying the contrasting answers to the foundational question about reference (What makes it the case that a name has the referent it has?) are contrasting strategies for answering parallel foundational questions about mental states: What makes it the case that a thought – a judgment or an intention – has the content it has, or is about what it is about? The argument sketched above against the possibility of a Millian semantics for an actual language rests on the assumption that thoughts can be about particular things only by expressing general concepts that apply to those individuals. If this were right, then the kind of causal-chain or historical-explanation story that Kripke and Keith Donnellan told to answer the foundational question about semantics would be an answer that detached the determination of the semantic values of expressions from the mental states and capacities of the users of the expressions, and so would be an answer that was vulnerable to this argument. But why should we think that thoughts, any more than names, can be about individuals only by expressing general concepts?

In defense of his principle of identification and his argument against the Millian theory, Searle asks:

> What is it to *mean* or *intend* a particular object to the exclusion of all others? Some facts incline us to think that it is a movement of the soul – but can I intend just one particular object independent of any description or other form of identification I could make of it? And if so, what makes my intention an intention directed at just *that* object and not at some other? Clearly the notion of what it is to intend to refer to a particular object forces us back on the notion of identification by description. (Searle, 1969, p. 87)

The suggestion implicit in these rhetorical questions is that an intention to refer to a particular individual must be explained as a behavioral capacity, the capacity to give a general description, or otherwise identify an individual who is, by fitting the description or being the object identified, the object meant or intended. The only alternative, it is implied, is some kind of obscurantist intentional magic, some kind of movement of the soul.

Even if Searle were right in his suggestion that intentions and other intentional states directed at particular individuals must be explained in terms of the capacities of the agent to identify the individual, this would still not give him the additional premise needed for the argument against the possibility of a Millian semantics for names. For Searle is not arguing that we cannot have intentions and other attitudes toward particular individuals; he is only arguing for a condition that is necessary for having such intentions and attitudes. What he needs for the argument is a constraint on the content of the attitudes we can have; but what he offers instead is a constraint on the conditions under which one can have attitudes with a certain kind of content. Whatever it is that constitutes intending and having knowledge and beliefs about a particular object, "to the exclusion of all others," so long as it is possible to have such intentions, knowledge, and beliefs, it will be possible to understand and speak a language with a Millian semantics.

But in any case, there is no real argument for the conclusion that mental magic is the only alternative to an explanation of intentionality in terms of an agent's capacities to identify. A causal account of intentional content – an explanation that looks back to how mental states came to be, rather than only forward to what those states dispose the agent to do – is equally compatible with a non-obscurantist account of intentionality. A causal account of intentions and beliefs seems, in fact, to be presupposed by the defense of a causal account of reference given by Kripke and Donnellan, since it is argued that speakers not only can refer, but can intend to refer, to particular individuals without being able to describe or identify those individuals. Causal and non-causal accounts of how names get their reference can share the assumption that reference is determined by intentions. The causal theory of reference is causal because it assumes a causal account of the content of the intentions that determine reference.

An argument of Michael Dummett's for the impossibility of a Millian semantics, like the argument I have sketched, bases this conclusion on the impossibility of a certain kind of knowledge: what Dummett calls *bare knowledge of reference*. Here is his characterization: "A *bare* knowledge of the reference of the name *a* will consist … in knowing, of some object, that *a* refers to it, where this is a *complete* characterization of this particular piece of knowledge" (Dummett, 1991, p. 127). I am not sure what Dummett means by a "particular piece of knowledge," or what it is for a characterization of such a piece to be complete; but if we interpret Dummett's arguments in the context of the possible-worlds conception of content, I think it is reasonable to identify his notion of bare knowledge of reference with knowledge of a singular proposition – the proposition that is true in a possible world if and only if a certain particular individual is the referent of the name *a*. An essential step in Dummett's argument for the impossibility of bare knowledge of reference is a claim that is essentially equivalent to Searle's principle of identification: we cannot have what Dummett calls knowledge-what – knowledge *of* a certain individual that it has some property F (for example, knowledge of a certain individual that it is the referent of the name *a*) – unless we have the capacity to describe or identify the object. More strongly, for any true knowledge-what ascription, there must be a true propositional-knowledge ascription whose content is a non-singular proposition that makes the method of identification explicit, and that entails the knowledge-what ascription: a propositional-knowledge ascription on which the knowledge-what ascription "*rests*" (Dummett,1991, p. 130). Now, I am not persuaded that this claim is correct; but even if this much is granted, I don't think it gives one reason to reject the possibility of knowledge of singular propositions. Suppose we grant that one cannot know of some particular individual x that it is F unless for some G one identifies x as the G,

and knows that the G is F. Further, suppose we grant that in a particular case the claim that y knows of x that it is F rests on, and is entailed by, the claim that y knows that the G is F. What has been granted is a claim that certain conditions are necessary, and others sufficient, for having knowledge of a certain kind; but nothing follows from this about the content of that kind of knowledge. If "bare knowledge" of some object, that *a* refers to it, is taken to mean knowledge that can exist in isolation, without knowing anything else about what *a* refers to, then we can grant that bare knowledge of reference is impossible; but that does not imply that knowledge of x, that *a* refers to it, is not knowledge of a particular proposition, a singular proposition, or that it is not possible to have knowledge of such propositions.

We can agree with Dummett that it is a difficult problem to say just what conditions must be met for one to know who or what the referent of a name *a* is, and that the problem is not solved simply by saying that to have such knowledge-what is to know a singular proposition of the form "x is the referent of *a*." But the problem is not that saying this would be wrong; it is just that specifying the content of a knowledge ascription is not the same as saying what it is for that knowledge ascription to be true.

The distinctions, on the level of both speech and thought, between questions about what content is and about how content comes to be determined, help to open up a place in conceptual space for a causal account of reference and of intentionality generally, and provide a rebuttal to arguments for the impossibility of a Millian semantics for a realized language. They do not, of course, end the debate. Once theoretical obstacles to such accounts are removed, examples and untheoretical considerations make a strong *prima facie* case for the claim that some such account is correct; but, as Gareth Evans reminded Kripke, "the deliverances of untutored linguistic intuition may have to be corrected in the light of considerations of theory" (Evans, 1982, p. 76). I think more theoretical considerations also support causal accounts of intentionality, but that is a different part of the story. I want to turn back now to questions about the relation between reference and metaphysical necessity.

5 Names and Essences

Whatever the fate of the debate between them, we have a stark contrast between two pictures of the way we are related, both by speech and by thought, to particular things in the world. On one picture, we can think and talk directly about particular things in virtue of our causal interaction with those things; on the other, our mental and linguistic acts relate us to particular things only by our grasping and expressing purely qualitative concepts that may be instantiated by particular things. The question now is, do these pictures of mental and linguistic representation either presuppose or support some particular conception of the nature of the particular things that we talk and think about, or that instantiate our concepts? Specifically, does the conception of reference that Kripke argues for presuppose or support the particular brand of essentialism that he defends? The two kinds of issues, I will argue, are independent. The only role of the theory of reference in Kripke's arguments for metaphysical conclusions is to help diagnose and rebut fallacious arguments that rest on a conflation of the two kinds of issues.

One of Searle's arguments against the Millian account of proper names was that it (or at least an "uncritical acceptance" of it) leads us into some "metaphysical traps" (Searle, 1969, p. 163). It is suggested that this conception of proper names presupposes "a basic metaphysical

distinction between objects and properties or aspects of objects" (p. 164). Actually, Searle's attitude toward the relation between the metaphysical and the semantic issues is not entirely clear. Does he locate the mistake in the premise – the Millian semantics for names – or in the inference from this premise to a metaphysical conclusion? On the one hand, we are warned against "the original sin of metaphysics, the attempt to read real or alleged features of language into the world" and "the metaphysical mistake of deriving ontological conclusions from linguistic theses" (p. 164); but on the other hand, the fact that the Millian account of names seems to presuppose this metaphysical distinction is part of an argument against that semantic account. It cannot be a good argument against a semantic account of proper names that someone has illegitimately drawn metaphysical conclusions from that account. So perhaps the view is that the Millian theory of names is already a covertly metaphysical thesis: that false metaphysical conclusions are validly drawn from it because the thesis is the result, rather than the occasion, for reading alleged features of language into the world. But if so, can't we separate the semantic from the metaphysical aspects of the thesis, and evaluate the semantic thesis independently of the metaphysical conclusions that are illegitimately drawn from it? If we couldn't make such a separation, then it would not be so clear that it was illegitimate to draw ontological conclusions from linguistic theses.

Searle's target is the Wittgenstein of the *Tractatus*, and not Kripke (whose lectures were given after Searle's book was published). But Kripke does make the kind of metaphysical distinction between objects and properties that Searle rejects; and, of course, he also defends the account of names that Searle argues is the illegitimate source of the metaphysical distinction. I will sketch the way Kripke makes the metaphysical distinction, and then argue that his metaphysical theses are compatible with the Fregean picture of mental and linguistic representation, and so do not presuppose the Millian semantics or the causal theory of reference. What is presupposed in the defense of Kripke's metaphysical conception is only that the two accounts of reference and intentionality not be conflated. I will conclude by considering whether there is a dependence that goes in the other direction: whether the semantic picture that Kripke defends presupposes his metaphysical theses about the relation between individuals and their properties. Here the issues are harder to disentangle, but I will argue that the Millian theory of names and the causal theory of reference are compatible with alternative metaphysical conceptions of individuals and their properties. There is no derivation of metaphysical conclusions from semantic premises.

What is it to make a basic distinction between objects and properties? Searle derided the metaphysical picture of an object as "a combination of its propertyless self and its properties," as well as the contrasting picture of an object as nothing but "a heap or collection of properties" (1969, p. 164); but what do these pictures really come to? Kripke also scorned the same two contrasting pictures, rejecting the assumption that objects are some kind of "bare particulars" or "propertyless substrata underlying the qualities," as well as the claim that they are nothing but bundles of qualities, "whatever that may mean" (Kripke, 1980, p. 52). The possible-worlds framework suggests a way to express the idea that a particular is conceptually separable from its properties without relying on the rejected picture of a bare particular. Properly understood, the issue concerns the modal properties of an individual. Intuitively, it seems clear that ordinary things might have had different properties from the ones they in fact have: Shakespeare might not have written plays, which, in the possible-worlds paraphrase, is to say that there is a possible world in which Shakespeare did not write plays. This possible world is one in which the very person who actually wrote the plays we know and love exists, and did not write plays. So (assuming the modal claim is

right) the property of writing plays is not essential to a particular person who has this property. The same goes for lots of other ordinary properties ascribed to ordinary persons and things; but not to all of them. Shakespeare obviously could not have been someone other than Shakespeare (although he could have been called something else), and according to Kripke he could not have been a member of a different species, or even have had different parents. Now these simple modal claims say nothing about names or reference; but in stating them I am using the proper name "Shakespeare," so the content of what I am saying about counterfactual possibilities might be thought to depend on the semantics for names. If "Shakespeare" were an abbreviation for a definite description, as Russell argued, then the statement that Shakespeare might not have written plays, and its paraphrase, that there is a possible world in which Shakespeare did not write plays, would both be ambiguous. If, for example, "Shakespeare" were an abbreviation for "the most famous Elizabethan playwright," then on one interpretation the claim that Shakespeare might not have written plays would be the claim that there is a possible world in which the person who is the most famous Elizabethan playwright in that world did not write plays. This, of course, is not the claim that Kripke intended to make, and it does not seem, intuitively, that the words used to make the claim are open to such an interpretation. The modal claims, in either their ordinary form or in their possible-worlds paraphrases, do not seem ambiguous, but that is a linguistic intuition which is separable from the modal intuition about the person who is the referent, by whatever means, of the name "Shakespeare," the claim that is expressed by the other reading of the claim that the most famous Elizabethan playwright might not have written plays. Now on what I have been calling the Fregean conception of mental representation, perhaps we cannot have such modal intuitions about particular individuals, since perhaps, on that conception, the only way we can have any thoughts at all about an individual is to have beliefs about whomever it is that is presented to us in some particular way. But this does not matter to the issue, since the metaphysical intuition can be expressed in a perfectly general way: whoever the person is who fits our Shakespeare concept, that person might have been someone who didn't write plays. So the modal theses stand or fall independently of the success or failure of the defense of theses either about the semantics for proper names, or about the way our thoughts relate us to the individuals that are the referents of those names.

If both the Fregean conception of reference and intentionality that Searle favors and the alternative semantic conceptions that he criticizes are compatible with the metaphysical distinction between particulars and their properties, what is the source of his objections to this distinction? I think they derive from a conflation of the two semantic conceptions. By equivocating between the two semantic theses, one can argue from semantic assumptions to a metaphysical conclusion: On the Fregean picture, there is an analytic, and so necessary, connection between the name "Aristotle" and a cluster of properties, and so it is legitimate to conclude, as Searle does, that "it is a necessary truth that Aristotle has the logical sum [inclusive disjunction] of the properties commonly attributed to him" (Searle, 1969, p. 173). This claim, by itself, implies nothing about what must be true of the person Aristotle, and so raises no problems about the traditional distinction between objects and their properties. On the unequivocal Fregean picture, "Aristotle" means, roughly, whoever satisfies the cluster; so according to this semantic hypothesis, if the person Aristotle hadn't satisfied the cluster, he would not have been Aristotle, but he might still have existed. It is only when one combines the Fregean premise with the assumption incompatible with it, that the name "Aristotle" is a Millian name, that one can take the next step in the argument, the inference

from the claim that Aristotle satisfies the cluster, to the conclusion that it is true *of* Aristotle that he satisfies the cluster. As Searle says, "I wish to argue that though no single one of them is analytically true of Aristotle, their disjunction is" (p. 169). It is only when one has the conclusion that the person Aristotle is necessarily connected with the properties used to identify him that one has reason for skepticism about substance, and for the claim that "it is misleading, if not downright false, to construe the facts which one must possess in order to refer as always facts *about* the object referred to, for that suggests that they are facts about some *independently* identified object" (p. 93).

To make a positive case for his modal theses about individuals, all Kripke does is to develop the framework in which the theses can be formulated clearly and separated from theses about names and reference. The rest of the work is done simply by pointing out what seems from an intuitive point of view obviously true, once it is clear what the alternatives are. If Kripke's rhetorical style had been a little different, he might have made this point by saying that he was just assembling reminders, not putting forward theses. What philosophy does, he might have said, is simply to put everything before us (Wittgenstein, 1953, §§126–128).

Not all of the metaphysical claims about individuals that Kripke defends on intuitive grounds are equally compelling. On the one hand, it seems hard to deny that we can make intuitive sense of questions about the potentialities of particular individuals independently of the means used to refer to them. To suppose that Shakespeare never wrote plays is to envision a counterfactual situation in which Shakespeare – the man himself – wrote no plays. Other theses Kripke defends are more controversial from an intuitive point of view, particularly theses that deny that certain things are possible, or equivalently, that affirm that particular things have certain essential properties. Can I coherently suppose that Shakespeare – the man himself – had different parents from the ones he in fact had, or that he was born in a different century? Kripke would argue that if we think we can suppose these things, we are confused: if we think clearly about what we are trying to suppose we will see that these are not coherent counterfactual possibilities. Not everyone will share these intuitions, even after setting aside the bad reasons for resisting them that Kripke points out. The possible-worlds framework does not settle such metaphysical questions, or even tell us how they should be settled; its job is to raise them, and to make clearer what the alternative answers say.

I have argued that Kripke's metaphysical theses do not presuppose his theses on reference and intentionality. What about the other direction? Does the Millian semantics for proper names or the causal account of reference and intentionality presuppose the metaphysical picture that Kripke defends? The theses about names can easily be separated from the more specific essentialist theses, but the general metaphysical issues about the identification of individuals across possible worlds are more difficult to disentangle from the thesis that names are rigid designators whose reference is established by causal interaction between the speaker and the referent. A rigid designator is one which denotes the same individual in all possible worlds; doesn't this presuppose that the same individuals can be found in different possible worlds?

Consider the following anti-essentialist metaphysical picture, a version of the "bundle of qualities" conception of an individual rejected by both Kripke and Searle. According to this conception, a particular individual is just the co-instantiation of a certain set of qualities. If individuals are identified across possible worlds at all, it is only in virtue of some counterpart relation which is definable in terms of the relations between the bundles of qualities

co-instantiated in the different worlds. Consider first the pure Leibnizian version of this metaphysical picture, according to which particular individuals have all of their properties, including their relational properties, essentially. On this conception, not only is it a mistake to think that we can coherently suppose that Shakespeare – the person himself – had different parents, we cannot even make sense of a counterfactual possibility in which he ate a slightly different breakfast than he in fact ate on a certain morning, or even lived in a world in which slightly different events took place years after his death. The thesis that names are rigid designators is perfectly compatible with this uncompromising metaphysics, but the combination of metaphysical and semantic theses has no plausibility. It gives us the conclusion, for example, that the proposition expressed by the statement that Shakespeare wrote plays is one that is true only in the actual world, and so is one that entails every true proposition. Only God could know that Shakespeare wrote plays. We more limited creatures can know that "Shakespeare wrote plays" expresses a true proposition, and we can know that, whatever proposition it expresses, it is necessarily equivalent to the proposition expressed by "Elvis Presley played the guitar"; but so long as we are ignorant of any fact, we cannot know which proposition it is that these sentences express.

Giving up the Millian theory of names would not resolve the problem, since there is no plausibility in the assumption that however we refer to him, Shakespeare – the man himself – could not possibly have failed to write plays, or to eat what he in fact ate for breakfast. A less uncompromising version of this metaphysical picture gives a different account of what it is for an individual to have a property essentially. According to the liberal Leibnizian (Lewis, 1986, ch. 4), to say that Shakespeare – the person himself – might not have written plays is to say that a counterpart of that person in some possible world did not write plays, where the counterpart relation is reducible to some kind of qualitative similarity. The counterpart variation of the Leibnizian metaphysics of individuals is not a thesis about names, but is about the modal properties of individuals, however they are referred to. The difference between the unreconstructed Leibnizian theory and the counterpart version might still be construed as a semantic rather than a metaphysical difference, but it is a difference in the way complex predicates involving modality are to be interpreted, and by itself says nothing about how names are to be understood. But the absurd consequences drawn from the combination of the Leibnizian metaphysics and the Millian account of names were about the propositions expressed by simple sentences involving non-modal predicates. If "Shakespeare" is a Millian name, then "Shakespeare wrote plays" is true in a possible world only if Shakespeare himself wrote plays in that world, which means only in the actual world. The fact that we construe "could have written no plays" in such a way that "Shakespeare could have written no plays" is also true in (and only in) the actual world is beside the point.

One might try to reconcile the Leibnizian metaphysics in its counterpart variation with a version of the Millian semantics for names by reinterpreting the concept of a rigid designator in a way that parallels the reinterpretation of modal predication. Suppose we say that a designator is *quasi-rigid* (relative to a possible world w) if its referent in any possible world w′ is a counterpart of some particular individual in w. Then if "Shakespeare" is a quasi-rigid designator, relative to the actual world, "Shakespeare wrote plays" might be true in some other possible worlds – worlds in which a counterpart of Shakespeare wrote plays. The thesis that names are quasi-rigid designators is a kind of compromise between the Millian theory and the sense theory that accounts for some of the phenomena Kripke brought to our attention, but there are problems with it. First, if (as David Lewis has argued) an individual may have more than one counterpart in the same world, then the semantic value of

a name will not be determined by the individual. Suppose Shakespeare has two counterparts in some possible world, only one of whom wrote plays. Is "Shakespeare wrote plays" true in that possible world or not? To answer this we need to know which of two (or more) quasi-rigid concepts is expressed by "Shakespeare." Second, even if an individual has at most one counterpart in any possible world, a designator might be quasi-rigid relative to one possible world and not relative to another, since two counterparts of the same thing (in different possible worlds) need not be counterparts of each other.

Despite these problems, the basic Kripkean picture of the way the reference of names is determined might still be reconciled with this metaphysical theory. What is essential to Kripke's picture, I think, is the idea that the content of speech acts and mental attitudes may be determined as a function of particular things (and kinds) with which the speakers and thinkers interact. Whatever one's metaphysical presuppositions, it will be agreed that the way content and reference are determined by the facts will be context-dependent, and influenced by general beliefs, purposes, and assumptions. The counterpart-theorist's story about the background against which reference to a particular (world-bound) individual can determine a proposition will be different from the story Kripke might tell, but there is nothing in the counterpart-theorist's metaphysics that prevents him telling such a story.

The dialectic of this last discussion shows that metaphysical and semantic issues cannot be kept completely apart for at least two reasons. First, if semantic and metaphysical theses together yield implausible consequences, it may be a matter of dispute where the source of the problem lies. Second, some metaphysical theories may force a reformulation of claims about semantics and intentionality. But the possible-worlds framework helps to clarify the metaphysical alternatives, and to separate metaphysical from semantic issues so that each can be evaluated on its own terms.

Names and Rigid Designation

JASON STANLEY

The fact that natural-language proper names are rigid designators is an empirical discovery about natural language. However, unlike other empirical discoveries about language made in the past few decades, it is one which has been taken to have great philosophical significance. One reason for this is that it has helped simplify the formal semantical representation of ordinary modal discourse. But the central reason is that the discovery threatens a certain picture, the descriptive picture, of the content of names, upon which a great deal of philosophy was premised. (See Chapter 35, REFERENCE AND NECESSITY.)

This chapter is mainly intended to be a survey of both the background and contemporary discussion of this discovery. However, the survey takes place in the context of an evaluation of the extent to which the discovery that English proper names are rigid itself threatens the descriptive picture of the content of names. The goal is to show that the exact philosophical significance of the discovery that natural-language proper names are rigid designators is still, and should still be, a matter of controversy.

§1 discusses different explications of rigidity. §2 is devoted to a sketch of the development of the notion of rigidity. §3 is a discussion of the descriptive picture of the content of names. In §4, Kripke's argument for the thesis that natural-language proper names are rigid is outlined, as well as an argument based upon this thesis against the descriptive picture. Finally, the remaining three sections cover various possible defenses of the descriptive picture.

1 Rigidity

Rigidity is a semantic property of an expression. More specifically, it has to do with the evaluation of that expression with respect to other possible situations (or 'worlds'). There are many subtle issues involved in the notion of evaluating an expression with respect to a possible situation, some of which we will discuss in this chapter.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

But there are also some simple confusions about this notion. Before we begin our discussion of rigidity, it is important to dispel one such confusion.

On one way of understanding evaluation of a sentence with respect to another possible world, a sentence is true with respect to another possible world just in case, if the sentence were uttered in that other possible world, it would be true. However, this is decidedly *not* how to understand the notion of evaluation with respect to another possible world which underlies our modal discourse.

The correct notion of evaluation of a sentence with respect to another possible world involves considering the sentence as uttered in the *actual world*, rather than as uttered in other possible worlds. When the sentence is uttered in the actual world, it expresses some semantic value which is determined by how the words are used by speakers in the actual world. This semantic value is then evaluated with respect to other possible worlds. What the nature of the entity is which is evaluated with respect to other possible worlds – whether it is a "proposition" (what is said by an utterance of the sentence) or some other entity – is a difficult question, and one which we will address at the end of this chapter. But for now it is only important to note, as a preliminary to our discussion of rigidity, that what is at issue in evaluating a sentence with respect to another possible world does not involve considering that sentence as uttered in that other possible world, but rather considering the sentence as uttered in the actual world.

How an expression e is used by speakers in other possible situations is thus irrelevant to the question of what the extension of e is when evaluated with respect to those other possible situations. For instance, what the denotation of "Cayuga Lake" is with respect to another possible world has nothing to do with how the speakers of that world – if there are any – use the expression "Cayuga Lake." It just has to do with which object Cayuga Lake is in that world. Now that this possible confusion has been eliminated, we may turn to the notion of rigidity.

According to Kripke's characterization of rigidity, "a designator d of an object x is rigid, if it designates x with respect to all possible worlds where x exists, and never designates an object other than x with respect to any possible world."[1] This characterization, as Kripke intends, is neutral on the issue of the extension of the designator d in possible worlds in which x does not exist. That is, if d is a designator which satisfies the above criteria, there are three possibilities left open for d's extension in worlds in which x does not exist. First, d could designate nothing with respect to such possible worlds. Second, d could designate x in all such possible worlds (despite x's non-existence in those possible worlds). Third, d could designate x with respect to some such worlds, and designate nothing with respect to other such worlds.

These three possibilities determine three different species of rigidity. However, only the first two species deserve discussion; a designator in the third class is a hybrid, and there is no reason to countenance such expressions. In the rest of our discussion, I will not consider designators in this third class left open by Kripke's characterization of rigidity.

The first species of rigidity, corresponding to the first of the above possibilities, includes all and only those designators d of an object x, which designate x in all worlds in which x exists, and designate nothing in worlds in which x does not exist. Following Nathan Salmon (1982, p. 4), let us call these *persistently rigid designators*.

The second species of rigidity, corresponding to the second of the above possibilities, includes all and only those designators d of an object x, which designate x in all worlds in which x exists, and designate x in all worlds in which x does not exist; or, more simply,

designate x with respect to every possible world. Again following Salmon, let us call these *obstinately rigid designators* (Salmon, 1982, p. 4).

There are expressions which are uncontroversially rigid in both of the above senses. For instance, consider Kripke's class of *strongly rigid designators* in *Naming and Necessity* (Kripke, 1980, p. 48). This class contains the rigid designators of necessary existents. That is, this class contains all and only those designators d of an object x which exists in all possible worlds, which designate the same thing in all possible worlds (that is, x). For example, the descriptive phrase "the result of adding two and three" is a strongly rigid designator, since its actual denotation, namely the number five, exists in all possible worlds, and the phrase denotes that number with respect to all possible worlds. Strongly rigid designators clearly belong to both of the above classes.[2]

At several points in this chapter considerations in support of the notion of obstinate rigid designation over that of persistent rigid designation will be advanced. However, it is unclear to what degree issues about persistent rigidity versus obstinate rigidity are substantive, rather than merely disguised terminological discussions about how best to use the expression "evaluation with respect to a world." There is a sense of this expression in which it seems to presuppose the existence of the denotation in the world; and if someone is using the expression in this sense, then persistent rigidity might be the more appropriate notion. If, on the other hand, one has a purely semantical understanding of "denotation with respect to a world," then the fact that the semantic rules directly assign a denotation to an expression might lead us to think that even in worlds in which that object does not exist, it is still the denotation of the relevant expression. But these are certainly just terminological issues.[3]

A further distinction is often made in discussions of rigidity: that of Kripke between *de jure* rigidity and *de facto* rigidity (see Kripke, 1980, p. 21, n. 21). An expression is a *de jure* rigid designator of an object just in case the semantical rules of the language unmediately link it to that object. All other rigid designators of objects are *de facto* rigid designators of them. To give an example from Kripke, the description "the smallest prime" is supposed to be *de facto* rigid, because it is not metaphysically possible for there to be a smallest prime distinct from the actual smallest prime, that is, two. The fact that "the smallest prime" denotes the same object in every world flows not from semantics, but from the metaphysical fact that mathematical facts are true in all metaphysically possible worlds. If, on the other hand, the semantical rule for a term t takes the form of a stipulation that it denotes a certain object x, then t is *de jure* rigid, since it is part of the semantical rules that it denotes that object.

The intuitive content of *de jure* designation lies in the metaphor of "unmediated" reference. A rigid *de jure* designator is supposed to denote what it denotes without mediation by some concept or description. A *de facto* rigid designator, on the other hand, is supposed to denote what it denotes in virtue of its denotation meeting some condition. That is, a *de facto* rigid designator denotes via mediation of some concept or description.[4]

The core notion of rigidity has been taken by philosophers to be *de jure*, obstinate rigidity. This is the notion which lies at the center not only of Kripke's work, but also of David Kaplan's work on direct reference (see Kripke, 1980, p. 21, n. 21; Kaplan, 1989a; and, most explicitly, Kaplan, 1989b, pp. 569–571; see also Chapter 38, THE SEMANTICS AND PRAGMATICS OF INDEXICALS). We will give some (albeit not so weighty) reasons in future sections for preferring obstinate rigidity over persistent rigidity. But we shall see already in the next section why the *de jure* character of rigidity is thought to be important. For rigidity arose in the development of the semantics of Quantified Modal Logic (henceforth QML), and in

particular, as a part of the explanation of the proper treatment of variables in QML. In that context, there is no question that *de jure* rigidity is the relevant concept.

2 Rigid Designation and Quantified Modal Logic

The pre-theoretic notion of rigidity began its life as a concept in the semantics for QML. In particular, rigidity arose in connection with the 'objectual' interpretation of QML, where the quantifiers were taken to range over objects, rather than non-constant functions. Even more specifically, rigidity was relevant to issues concerning Quine's "modal paradoxes," raised as objections to the coherence of QML. In this section, I will attempt to show where the notion of rigidity enters into the attempt to give a coherent and natural semantic interpretation to QML.

One of the first issues which arose in QML was what the proper intended interpretation of quantification should be. The two camps in the 1940s were the conceptual interpretation, championed by Alonzo Church and Rudolf Carnap, and the objectual interpretation, championed by Ruth Barcan Marcus.[5] But while Church, Carnap, and Barcan Marcus and others were developing axiom systems for QML, Willard Van Orman Quine was busy attempting to demonstrate their incoherence.

Quine raised two influential objections to QML (Quine, 1943).[6] According to the first of these objections, quantification into modal contexts violated fundamental logical laws. According to the second (and obviously related) objection, if QML and its intended interpretation could be so formulated as to evade the first objection, then it would inexorably carry with it unpalatable metaphysical commitments.[7] Since the defenders of QML partially defined their own positions against the first of these objections, something must be briefly said about it here. Following this we will outline the conceptual interpretation of QML, and then the objectual interpretation, explaining how their original espousers evaded Quine's worry.[8]

According to the principle of substitution, for any terms a and b, if "a = b" is true, then for any formula φ containing "a," the result of replacing one or more occurrences of "a" by "b" does not change the truth-value of φ.[9] However, according to Quine, QML essentially involved a violation of this principle. For "nine = the number of planets" is true. Furthermore, "Necessarily, nine = nine" is true. But the result of substituting "the number of planets" for the first occurrence of "nine" in "Necessarily, nine = nine" yields a falsity, namely, "Necessarily, the number of planets = nine."

Quine took the failure of substitution in modal contexts also to demonstrate the failure of existential generalization in QML. That is, Quine took the failure of substitution to show that the inference from "$\Box Fa$" to "$\exists x \Box Fx$" is illegitimate. The reason Quine thought that a failure of substitution demonstrated the failure of existential generalization is that he thought that substitutability by co-referential terms was a *criterion* for the legitimacy of quantifying in.[10]

Here is one reason why Quine thought that the substitutability of co-referential terms in a linguistic context C was a criterion for the legitimacy of quantification into C. Consider a quotational context, such as:

(1) The first sentence of the (English translation of the) *Duino Elegies* is "Who, if I cried out, would hear me among the angels' hierarchies?"

Inside such a quotational context, substitution of co-referential terms fails to preserve truth-value. For example, (1) is true, but (2), which results from (1) by the substitution of co-referential terms, is false:

(2) The first sentence of the (English translation of the) *Duino Elegies* is "Who, if Rilke cried out, would hear Rilke among the angels' hierarchies?"

Thus, substitution of co-referential terms fails in quotational contexts.

But it is also illegitimate, according to Quine, to quantify into such contexts. To see this, consider the sentence:

(3) There is something x such that "Who, if x cried out, would hear x among the angels' hierarchies?" is the first sentence of the *Duino Elegies*.

Sentence (3) is false. The reason (3) is false is, as Quine is fond of pointing out, that the quoted sentence in (3) names not some sentence which results from replacing 'x' by a term, but rather a sentence containing the symbol 'x.' That is, a quotation such as "'x flies'" denotes the result of concatenating the symbol 'x' with the word 'flies,' not the concatenation of some replacement term for 'x' with "flies." Thus, for Quine, it is illegitimate to quantify into quotational contexts.[11]

But Quine does not simply conclude from the failure of both substitution and quantifying into quotational contexts that substitution is a criterion for quantifying in. For Quine, the failure of substitution in a linguistic context demonstrates a deep incoherence in quantifying into such contexts. For in giving the semantics of a quantified sentence, one must avail oneself of the notion of satisfaction; the sentence is true just in case some object satisfies the relevant open sentence. Yet, for Quine, the failure of substitution shows that there is no available notion of satisfaction in terms of which one can define the truth of such sentences. There is no notion of objectual satisfaction for quantifying into quotational contexts, for instance, because such contexts are sensitive not just to objects, but also to how they are named.

Thus, for Quine, the failure of substitution in modal contexts demonstrated that there was no appropriate notion of objectual satisfaction for open formulas such as "$\Box$Fx." For the failure of substitution seemed to show that whether or not an object satisfied an open, modalized formula depended upon how the object was named. Quine hence thought there was a similarity between modal and quotational contexts: in both cases, what matters is how the object is named, rather than just the object itself. Quine concluded that there was no way of giving a coherent semantics for sentences such as "$\exists x \Box Fx$," since there was no available notion of satisfaction in terms of which one could define the truth of the sentence. He hence declared that quantification into modal contexts was illegitimate (since incoherent), and that existential generalization fails.

There is also a historical reason for Quine's analogy between modal and quotational contexts: for Quine's target, Carnap, wished to explicate necessity in terms of the analyticity of certain sentences. That is, Carnap in *Meaning and Necessity* believed that to say that a certain proposition was necessary was "really" to say, of a certain sentence, that it was analytic (Carnap, 1988, p. 174). Thus, according to Carnap, a construction such as (a) "really" expressed (b):

(a) Necessarily, bachelors are unmarried men.
(b) "Bachelors are unmarried men" is analytic.

So, according to Carnap, modal contexts were really disguised quotational contexts. If so, then quantifying into modal contexts seems tantamount to quantifying into quotational contexts.

There are several responses which have been given to Quine's challenge. One response stems from the interpretation of QML which emerged from the work of Church and Carnap. According to this approach, variables in modal languages ranged over individual concepts, describable (in contemporary terms) as functions (possibly non-constant) from possible worlds to extensions. The principle of substitution, on this approach, was interpreted as licensing not substitution of terms for two extensionally equivalent individual concepts (that is, functions which yield the same denotation in the actual world), but rather, substitution of terms which denote the same individual concept.

Now, "nine" and "the number of planets" do not express the same individual concept, for though they are extensionally equivalent, there are possible situations in which the extension of "the number of planets" is different from the extension of "nine." Thus, the principle of substitution does not license the substitution of "the number of planets" for "nine," on this account of QML. Furthermore, any two expressions which do express the same individual concept (are "L-equivalent," in Carnap's terms) will be substitutible, even in modal contexts.

This 'conceptual' interpretation of QML thus has a systematic, logically consistent account of the notion of the satisfaction of an open-modal formula (cf. Church, 1943; Carnap, 1988, §§43 and 44). On the conceptual interpretation of QML, one can take the quantifier in "$\exists x \Box Fx$" to range over individual concepts. In this case, the relevant notion of satisfaction is satisfaction by individual concepts, rather than objects.[12]

However, the conceptual interpretation of QML does not seem to accord with our natural interpretation of QML. The sentence:

(4) $\exists n$ ($\Box$n numbers the planets)

is intuitively false on a natural reading of the quantifier (cf. Garson, 1984, pp. 265–267). The reason it seems false to us is that, according to a very natural reading of (4), what it asserts is that there is some object which necessarily numbers the planets. However, on the conceptual interpretation, (4) is true, because the individual concept expressed by "the number of planets" will satisfy the open formula:

(5) $\Box$n numbers the planets

since, in every possible world, the number of planets numbers the planets.

What such examples suggest is that the natural reading of quantification into modal contexts is as quantification over objects, rather than over individual concepts. If we wish to capture this intuition, then we should think of, say, an existential quantification into an open-modal formula (henceforth OMF) as true just in case some object satisfies the relevant modal condition.[13] On this account, which we shall call the objectual interpretation of QML, the first-order quantifiers range only over objects, rather than over concepts.

According to the objectual interpretation, a sentence such as "$\exists x \Box Fx$" is true just in case some object is necessarily F. But what about Quine's worry? Can the objectual interpretation supply a natural account of the satisfaction of OMFs?

An OMF, such as "□Fx," is, on the objectual conception, satisfied by an assignment just in case the object which that assignment assigns to 'x' is necessarily F, that is, is F with respect to every possible situation, *irrespective of any names of that object*. We are not to understand the satisfaction of such an OMF "substitutionally," as satisfied by an assignment, just in case, for some name a of the object which that assignment assigns to 'x,' the sentence, "□Fa" is true. Rather, we are to read "□Fx" as satisfied by an assignment s just in case the object which that assignment assigns to 'x' satisfies F with respect to every possible situation.

This understanding of the satisfaction clause for OMFs undercuts Quine's objection to the coherence of quantifying into modal contexts. For Quine's worry can only arise if objectual satisfaction is characterized in terms of the truth of closed sentences containing names of the alleged satisfiers. Only if objectual satisfaction is given such a substitutional construal is it relevant to the coherence of quantifying into modal contexts that two closed modalized sentences, differing only in containing different names for the same object, may differ in truth-value.[14]

If such a notion of an object satisfying a predicate necessarily indeed makes sense, then it is possible to quantify into modal contexts despite the failure of substitution. Of course, Quine's *other* objection to QML is that, where the necessity in question is metaphysical, this notion involves a dubious metaphysic of essentialism. But discussion of this question will take us too far away from the topic of rigidity (see Chapter 34, ESSENTIALISM, and Chapter 35, REFERENCE AND NECESSITY).

This construal of the satisfaction of OMFs, combined with possible-world semantics, naturally brings with it an interpretation of variables according to which they are *de jure* rigid designators. To see why this is so, consider a sentence of QML such as "$\exists x \Box(\text{Exists}(x) \rightarrow \text{Rational}(x))$."[15] According to the objectual interpretation of QML, this sentence is true just in case there is some assignment function which assigns to the variable 'x' an object o which, in every possible situation, satisfies the open formula "$\text{Exists}(x) \rightarrow \text{Rational}(x)$." The evaluation of the truth of the sentence hence involves, relative to an assignment function, evaluating the open formula "$\text{Exists}(x) \rightarrow \text{Rational}(x)$" with respect to every possible situation. Since, in each possible situation, we are considering whether or not the object o satisfies the formula, we need to ensure that the variable 'x' denotes o in all of the possible situations. That is, on the objectual interpretation of QML, when taken with respect to an assignment s, variables are rigid designators of the objects which s assigns to them. The reason that variables are *de jure* rigid designators is because there is nothing else to the semantics of variables besides the stipulation that, when taken with respect to an assignment s which assigns the object o to a variable, it designates o in every possible situation.[16]

If we understand variables as rigid designators (with respect to an assignment), then the following version of substitution is validated:

(6) $\forall x \forall y[x = y \rightarrow [\varphi \leftrightarrow \psi]]$

(where φ differs from ψ only in containing free occurrences of "x" where the latter contains free occurrences of "y"). For even if φ and ψ contain modal operators, the rigidity of the variables will guarantee the inter-substitutability of "x" and "y."

The situation is slightly more complicated in the case of terms. Quine's challenge is to validate, not just (6), but also the fully schematic version of substitution:

(7) $t = s \rightarrow (\varphi \leftrightarrow \psi)$

(where φ differs from ψ at most in containing occurrences of t where the latter contains occurrences of s, and no free variables in t and s become bound when t and s occur inside φ and ψ). But where t and s are replaceable by non-rigid designators, then (7) will, in the modal case, fail to be valid; thus the defender of the objectual interpretation who wishes to preserve full classical substitution must disallow non-rigid terms from her language.

There are also other motivations for restricting the class of terms to rigid ones on the objectual interpretation. For example, to do so would allow a uniform treatment of the class of terms. If all terms are rigid, then non-variables can be treated in the semantics as free variables whose interpretation does not depend on assignments.[17] Another reason is that, if one allowed non-rigid designators, one would have to restrict universal instantiation (UI) to rigid designators to retain (6), and some might hold that such a restricted UI rule is unappealing. Finally, non-rigid terms raise further technical problems which, though certainly solvable, nevertheless complicate the semantics.[18]

At this point the reason for the introduction of terms which directly represent objects is purely technical – it is a technical response to a logico-semantical dilemma. If one wishes to preserve classical substitution, as well as the objectual conception of satisfaction, then one must ensure that one's variables and terms are rigid. In availing ourselves of such terms, there is no commitment to thinking that any terms in ordinary language are rigid. Rigid terms only play the role, at this stage, of desirable formal-semantical tools, which allow us a better grasp of the objectual notion of satisfaction, as well as an explanation of the validity of classical substitution.

However, if we wish QML to serve as a representation of ordinary modal discourse, then the rigidity constraint on terms may seem problematic. Without a philosophical justification of this restriction, or a semantical argument to the effect that natural-language terms are rigid, this restriction is *ad hoc*. If natural-language singular terms are non-rigid, then the extra logico-semantical complexities which attend the addition of non-rigid terms into QML will either have to be accepted as realities or used as a basis for rejecting its coherence.[19]

Even in the late 1940s it was recognized that a philosophical/semantical argument demonstrating the rigidity of natural-language terms would be desirable.[20] However, it was not until the seminal work of Saul Kripke in 1970 that a fully explicit argument for this conclusion was forthcoming. But Kripke's ambitions went far beyond demonstrating that natural-language terms are rigid. For Kripke used the notion of rigidity as a basis for quite substantive claims about the nature of intentionality. It was thus with Kripke that the *philosophical* construal of rigidity began.

3 The Descriptive Picture

According to the picture of intentionality attacked by Kripke, the way our words hooked onto an extra-linguistic reality was via description. That is, a name such as "Aristotle" denoted the person, Aristotle, because the name was associated with a series of descriptions (such as "the last great philosopher of antiquity") which were uniquely satisfied by the person Aristotle. More relevant for our purposes, however, is Kripke's attack on the descriptive picture of the *content* of proper names. According to this, the content of a name was given by the description which fixed its referent. That is, what someone said when they uttered a sentence such as "Aristotle is F" was a descriptive proposition to the effect that, say, the last great philosopher of antiquity, whoever he was, is F.

Kripke (1980) first demonstrated that ordinary-language proper names were rigid. He then used this feature of names as part of a larger attack on a certain version of the above picture of content.

In the next section, we will discuss how Kripke used rigidity to attack the descriptive picture. But before we do so, it is important to gain an understanding of what the descriptive pictures of intentionality and content are. In particular, we will distinguish between two different versions of the descriptive picture which are often not distinguished in the literature.

The problem of linguistic intentionality, in one of its forms, is the question of what it is in virtue of which an expression has the reference it does. According to the first descriptive picture of linguistic intentionality, what it is in virtue of which a primitive expression has the referent it does is that it is associated with a set of descriptions, in purely general, non-indexical, or particular involving terms. These descriptions are uniquely satisfied by an entity which then counts as the reference of that term.

A less problematic and more commonly held version of the description theory dispenses with the requirement that the descriptions which fix referents must be given in purely general terms. According to this version, which is most explicit in the works of Strawson and Dummett, but at least implicit in Frege, the descriptions which fix referents can, and indeed often must, contain non-descriptive elements.[21]

It is worthwhile to mention briefly a motivation for the latter picture of intentionality. One might think that, in the case of demonstrative reference, one has reference without any description. But this is merely a myth. Suppose I point to a brown table, and say, "This is brown." It is not my pointing alone which fixes the reference of the occurrence of "this," for my finger will also be pointing at the edge of the table, or a small brown patch on the table. Rather, a factor in fixing the reference of my demonstrative is that I intend to be demonstrating some object whose identity criteria are those of tables, rather than those of small brown patches or edges. Such identity criteria play a crucial role in overcoming the massive indeterminacy of ostensive definition. It is for their specification that descriptive material is required.[22] But this insight in no way requires that we ignore the non-descriptive element inherent in true demonstrative reference (see Chapter 39, OBJECTS AND CRITERIA OF IDENTITY).[23]

A final relevant factor which distinguishes descriptive accounts of intentionality from each other has to do with the role of the social. According to Russell, as well as the account of descriptive intentionality attacked by Kripke (1980), a term refers, in the mouth of a speaker, to that object which satisfies the descriptions the *speaker* associates with the term. However, according to other traditional descriptive accounts, such as that of Strawson (1959, pp. 151 ff.), what is relevant is not which descriptions the speaker associates with the term, but rather, which descriptions are associated with the term in the language community. On this latter, more plausible account, a use of a term in the mouth of a speaker refers to the object it does in virtue of her participation in a language community which associates certain descriptions with that term that are uniquely satisfied by the object in question.[24]

There are thus two different versions of the descriptive picture, one according to which the descriptions must be in general terms alone, and another in which they may contain irreducible occurrences of demonstrative and indexical expressions. Each of these two versions has two sub-versions: one according to which it is the descriptions the speaker associates with a term which are relevant for determining the reference of terms she uses, and the other according to which it is the descriptions the language community of the speaker associates with the term which determine the reference of the term when she uses it.

Each of these versions corresponds to a theory of the content of sentences containing proper names. On the first picture, utterances of sentences containing proper names express descriptive propositions, where the relevant descriptions only contain expressions for general concepts. According to the second version of the description theory, utterances of sentences containing proper names also express descriptive propositions. However, these descriptive propositions typically are also irreducibly indexical propositions. So, on this latter account, a sentence such as "Bill Clinton is F" would state some proposition equivalent to what is expressed by "The *present* president around here of the United States is F."[25]

If the descriptive picture is true, then, for each expression in our language, we possess, *a priori*, uniquely identifying knowledge about its referent. Such a premise is more than just a useful tool in epistemological and metaphysical theorizing. For if the descriptive picture is true, then we have a rich store of *a priori* knowledge. This makes more plausible a classic picture of philosophy, according to which it proceeds by *a priori* methods. The Kripkean challenge to the descriptive picture is thus not merely a challenge to an empirical thesis, but also threatens to undermine deeply rooted conceptions of the nature of philosophy.

4 Kripke's Argument and the Rigidity Thesis

I will not go into great detail in this chapter about Kripke's larger critique of the descriptive picture of intentionality and content, as the issue is covered in another chapter in this volume (see Chapter 35, REFERENCE AND NECESSITY). In this section I will first describe an argument, due essentially to Kripke, for the thesis that names are rigid designators. I will then conclude with an argument from rigidity against the descriptive picture of content.

One of the central contributions of Kripke (1980) lay in the argument that natural-language proper names are rigid designators (where "rigid designator" is taken in the first, neutral sense of §1). In what follows, we will go through this argument. More exactly, what we will motivate is the following thesis, which I will call RN, the Rigid Name thesis:

(RN) If N designates x, then N designates x rigidly

where "N" is replaceable by names of English-language proper names. Throughout the argument for RN, it will be assumed that variables under assignments are rigid designators, and it will be argued from this assumption that natural-language proper names are also rigid designators.[26]

According to the neutral characterization of rigidity, a designator D of an object x is rigid just in case, for all possible worlds w, if x exists in w, then D designates x in w, and if x does not exist in w, then D does not designate something different from x in w. There are thus three ways in which a designator D of an object x could fail to be rigid:

(a) There could be a world in which x exists, but is not designated by D.
(b) There could be a world in which x exists, but D designates something else.
(c) There could be a world in which x does not exist, and D designates something other than x.

It will be argued that each of these possibilities is ruled out in the case in which D is a proper name.

Before we proceed with the argument, it is worth noting that no separate proof is required for (b). Given that proper names designate, at most, one thing in each world, any situation in which x exists, but D designates something else will be a situation in which D does not designate x. That is, every (b) situation is an (a) situation. Thus, the demonstration that (a) is incompatible with D being a proper name will suffice to show that (b) is incompatible with D being a proper name.

So let us first argue that if "a" is a proper name designating x, then, in any world in which x exists, x is designated by "a." Suppose not, that is, suppose "a" designates x, and (a) is true. Then the following is the case:

(8) $\exists x\,[x = a\ \&\ \Diamond\,(x \text{ exists } \&\ x \neq a)]$

But (8) seems false when "a" is a proper name. Plugging an actual proper name in for "a" in (8) should make this clear:

(9) There is someone who is Aristotle but he could exist without being identical with Aristotle.

This is intuitively false. Thus, it seems that if N is a proper name designating x, then, if x exists in a world, then N designates it. So, we are done with case (a) as well as (b).

Now, let us turn to the argument that if "a" is a proper name designating x, then, in any world in which x does not exist, "a" does not designate something other than x. Suppose not, that is, suppose "a" designates x, and (c) is true. Then the following is the case:

(10) $\exists x\,[x = a\ \&\ \Diamond\,(a \text{ exists and } a \neq x)]$

But (10), like (8), seems false when "a" is a proper name. Substituting an actual proper name for "a" in (10) should make this clear:

(11) There is someone who is Aristotle but Aristotle could exist without being him.

Like (9), (11) also seems intuitively false. Thus, it seems that if N is a proper name designating x, then, if x does not exist in a world, then N does not designate anything else. So we are done with case (c), and the argument for (RN).

The argument for (RN) exploits speaker's intuitions about the truth-value of instances of (8) and (10). In the case of normal proper names, it seems true that, when substituted for "a" in (8) and (10), a false sentence results. (RN) is thus an empirical claim about natural language. As such, it has been challenged. That is, some have maintained that there are true instances of (8) and (10). However, the proper names that are typically considered are somewhat elaborate, involving issues in metaphysics that are beyond the scope of this chapter. The literature on "contingent identity-statements" will thus not be discussed in what follows.[27]

In the above description of Kripke's argument, I have been using the expression "rigid designator" in the sense of a term which denotes its actual denotation in all possible worlds

in which that denotation exists, and nothing else in other worlds. But there are also some considerations which some have felt mitigate in favor of the thesis that names are obstinately rigid designators. For instance, Kripke (1980, p. 78) gives as an example the sentence:

(12) Hitler might never have been born.

Sentence (12) is true. But (12) is true just in case the sentence, "Hitler was never born" is true when evaluated with respect to some possible world. If "Hitler" does not denote anything with respect to that world, then, unless one gives sentences containing non-denoting terms truth-values, it will be impossible to make the sentence "Hitler was never born" true in that world. But, if "Hitler" denotes Hitler in that world, then, despite the non-existence of Hitler in that world (or perhaps because of it), the sentence "Hitler was never born" can be true in that world.

This argument is, however, unimpressive. For it relies on the thesis that sentences containing non-denoting terms receive no truth-value. If one said that sentences containing non-denoting terms were false, then analyzing "Hitler was never born" as the negation of "Hitler was born" in a world in which "Hitler" is non-denoting would yield the correct prediction.[28]

Many have adverted, at this point, to a more indirect argument, one which exploits the analogy between tense and modality. A tense-logical obstinately rigid designator is one which denotes the same thing at all times, regardless of whether or not that thing exists at the time of evaluation. That proper names should be treated as tense-logical obstinate rigid designators is supported by the Montagovian example:

(13) John remembers Nixon.[29]

Example (13) can be true, as uttered in 1995, despite Nixon's non-existence at the time of utterance. Such evidence is taken, by the tight analogy between tense and modality, to support the modal logical obstinancy of proper names.[30]

However, examples such as (13) only demonstrate that proper names can denote individuals existing prior to, but not during, the time of evaluation. If proper names are to be true tense-logical obstinate rigid designators, then proper names of objects which exist subsequent to, but not during, the time of evaluation, should nonetheless denote at the time of evaluation. But this does not seem to be the case. For instance, consider the name "Sally," introduced in 1995 to denote the first child born in the twenty-first century. In the case of such a name, it is dubious that it denotes, as evaluated in 1995. For it is metaphysically likely that the future is open, and not already determined. If so, then there is no fact of the matter, in 1995, as to what the reference of "Sally" is now. Thus, it is unclear whether proper names are tense-logical obstinately rigid designators.

Whatever the outcome of the debate concerning the obstinancy of proper names is, it does seem that proper names are rigid designators. This would suggest that what fixes the referent of a proper name is not a non-rigid description, but rather something else. If so, then the descriptive account of intentionality would seem to be false.

This argument, as Kripke recognized, is, however, too swift. For it collapses once one makes Kripke's useful distinction between a description giving the content of a name and merely fixing its referent. If the description fixes the referent of a name then there is no

commitment to saying that the name denotes an object in other possible worlds in virtue of that object satisfying the description. On this picture, the description fixes the referent, which is then the denotation of the proper name, even in worlds in which the referent does not satisfy the description. Thus, there is no direct argument from rigidity against the descriptive picture of intentionality.

The case differs, however, with the descriptive picture of content. For there does seem to be an argument from rigidity against the thesis that the content of a proper name is descriptive. For suppose that the content of the proper name "a" is descriptive. In particular, suppose that its content is given by the non-rigid description "DD." Then the content of a sentence which results from replacing "N" by "DD" should stay unchanged, since "N" and "DD" have the same content. But, given that "N" is rigid and "DD" is not rigid, (14) and (15) do not have the same content, as (14) is true and (15) is false:

(14) N might not have been DD.
(15) N might not have been N.

Therefore, substitution of "DD" for "N" does not preserve truth-value, and hence also does not preserve content. Hence "DD" and "N" do not, after all, have the same content.

Let us take a concrete example. Suppose that the name "Aristotle" has the same content as the description, "the last great philosopher of antiquity." Then, replacement of "Aristotle" by "the last great philosopher of antiquity" should preserve content. But:

(16) Aristotle might not have been the last great philosopher of antiquity.
(17) Aristotle might not have been Aristotle.

differ in content, since (16) has a true reading (for instance, there is a reading of (16) where it is true because Aristotle might have died as a child, in which case he never would have become a philosopher at all), and (17) has no true reading.[31] Thus, "Aristotle" and "the last great philosopher of antiquity" are not inter-substitutable, and hence do not have the same content.

It thus seems that Kripke's demonstration that proper names are rigid also shows that they do not have descriptive content. An obvious next step is the thesis, which Kripke attributes to John Stuart Mill, that the content of a proper name is simply its denotation. However, Kripke does not, from rigidity alone, conclude that Millianism is correct;[32] rather, he only commits himself to the following minimal thesis, which I shall henceforth call the *Rigidity Thesis*, or RT:

> The rigidity of proper names demonstrates that utterances of sentences containing proper names, and utterances of sentences differing from those sentences only in containing non-rigid descriptions in place of the proper names, differ in content.[33]

If RT is correct, then the descriptive account of content would seem to be false. In the rest of this chapter, I shall focus on various ways of defending the descriptive account of content. In the next section, I will discuss a version of the descriptive account of content which is compatible with RT. After that, I will discuss critiques of RT.

5 The 'Actualized' Description Theory

RT raises a *prima facie* difficulty for descriptive theories of content. Since the most plausible meaning-yielding descriptions seem to be non-rigid, RT seems to demonstrate that descriptive accounts of content are false. However, this appearance is misleading. RT does not demonstrate that all descriptive accounts of content are false. In particular, RT is only incompatible with one of the two descriptive accounts of content distinguished in §3. As we shall see in this section, though RT is indeed incompatible with the thesis that the content of proper names can be given by description in purely qualitative, general terms, it is not incompatible with the more traditional descriptive account of content, according to which the descriptions which give the content of proper names may contain indexical expressions.

RT is incompatible with the purely qualitative description-theory of the content of proper names. For consider plausible meaning-yielding descriptions for an ordinary proper name, such as "Aristotle." Since the meaning of an expression is what one knows in virtue of which one is competent with that expression, such descriptions must be the things that are known by those competent with the expression. Examples of such descriptions are "the last great philosopher of antiquity," or "the teacher of Alexander." But these are non-rigid descriptions. RT is incompatible with such descriptions matching proper names in content.

On the other descriptive account of content considered in §3, the descriptions which give the content of proper names may contain indexical expressions: that is, expressions occurrences of which denote fixed parameters of a context. For instance, "I" denotes the speaker of a context, "now" the time of the context, and "here" the place of the context. (See also Chapter 38, THE SEMANTICS AND PRAGMATICS OF INDEXICALS.) But once one broadens one's perspective to include modal evaluation, it seems natural to add the word "actual" to the list. That is, once one is in the context of possible-worlds semantics, "actual" indicates the world of the context.[34]

If so – that is, if "actual" is an indexical – it would be bizarre, on an account of content according to which the descriptions which give the content of proper names may contain indexical expressions, to disallow its appearance in the content-yielding descriptive expressions. But descriptions which contain the word "actual" are rigid. That is, a description such as "the actual F" rigidly denotes the object which is in fact F, even in worlds in which that object fails to be the unique F. Indeed, someone sympathetic with this account of the descriptive picture of content, as well as RT, would simply conclude that the descriptions which give the content of proper names must contain the indexical "actual." Furthermore, on this account of content, it would not even be a surprising fact that the relevant descriptions must be "actualized," since, on this account of content, the arguments for the thesis that meaning-yielding descriptions must contain indexical expressions (for instance, Strawson's consideration of symmetrical universes) straightforwardly generalize to the modal case.

Now, if proper names are *de jure* rigid designators, then even this descriptive account of content would be false, for actualized descriptions do not "unmediatedly" designate. That is, a description such as "The actual teacher of Alexander" designates Aristotle via mediation of some concepts.[35] There are several responses to this point.

The first response to this point is that the argument for RN given in §4 does *not* (and was not, by Kripke, intended to) demonstrate that proper names are *de jure* rigid, but merely

that they are rigid. Second, given the metaphorical nature of the notion of mediation, it is difficult to see how one *could* argue for such a conclusion. Finally, there are examples of proper names which do seem, relatively uncontroversially, to rigidly designate what they designate "via mediation."

The first of these points is obvious. The statement of RN does not mention the notion of *de jure* designation. Furthermore, nothing in the argument for it would fail if proper names were only *de facto* rigid.

To grasp the second point, consider the case of indexicals, which are rigid designators. Does the word "I" designate what it designates via mediation, or not? Kaplan (1989a) seems to think it does not.[36] But "I," whenever it is used, designates the agent of the context. Though there are difficulties in making precise the notion of" agenthood" here, it is difficult to see how it could be that "I" designates "unmediately," given the linguistic rule that it is to designate the agent of the context. Perhaps there is a notion of mediation according to which "I" unmediatedly designates. But if so, it needs to be made more precise before an argument for such a conclusion can be evaluated.

Finally, there are examples of proper names which, if the notion of mediation is coherent, do seem to designate mediately what they designate. Consider, for example, the following example, due to Gareth Evans (1985b). Suppose we wish to discuss what the world would have been like if the zip had not been invented. In particular, we wish to discuss what would have happened if the inventor of the zip had died at birth. Not knowing who the inventor of the zip is, we introduce a name "Julius," by the following reference-fixing stipulation:

(S) Reference("Julius") = The inventor of the zip

and then go on to theorize about what would have happened had Julius died at birth, and had failed to invent the zip.

Evans's intuition is that "Julius" is a rigid designator. That is, according to Evans, (18) has no true reading, but (19) does:

(18) Julius might not have been Julius.
(19) Julius might not have been the inventor of the zip.

If so, then "Julius" is an example of a proper name which designates what it does via mediation, and is hence not *de jure* rigid.[37]

Given Evans's example, it seems implausible to maintain that it is a feature of the semantic category of proper names that they are *de jure* rigid. Of course, on the descriptivist account, *no* proper name is *de jure* rigid, which, given the slight oddity of "Julius"-type names, may seem worrisome. Nonetheless, what is important to note for our purposes is that there is no argument from rigidity alone against a traditional descriptive account of the content of proper names. Issues of rigidity are simply independent of the question of whether names have descriptive content.[38]

None of this would be news to Kripke. Kripke never argued that his modal considerations refuted every version of the descriptive account of content. Michael Dummett has, however, leveled more direct challenges to Kripke's conclusions.[39] Though Dummett agrees that Kripke has shown an important difference between English proper names and descriptions, he has challenged Kripke's contention that the difference in question always makes a difference to what is said. In particular, according to Dummett, the rigidity of proper names

does not affect the content of modally "simple" sentences, that is, sentences not containing modal terms. In other words, Dummett challenges the truth of RT.

Dummett's early views on rigidity can be separated into two doctrines. The first, which is a negative doctrine, is that rigidity does not make a difference to the content of simple sentences. The second, which is a positive doctrine, is that the phenomena which the notion of rigidity is intended to capture can be accounted for by a stipulation that terms which Kripke would classify as rigid take an obligatory wide scope with respect to modal operators.

In the next section I will discuss Dummett's positive doctrine, as well as Kripke's decisive objection to it. In the final section I will turn to a more promising line of argument against RT along essentially Dummettian lines.

6 Names and Wide-Scope

Consider again (16) and (17), which were used to show that "Aristotle" and "the last great philosopher of antiquity" have different contents. As we saw in §4, (17) has no true reading, whereas (16) does. If one assumes that "Aristotle" is rigid, whereas "the last great philosopher of antiquity" is not, then one can account for this contrast between the two expressions.

The point of Dummett's positive doctrine is that one can account for the distinction between (16) and (17) without supposing a difference in semantic value between "Aristotle" and "the last great philosopher of antiquity." That is, one can account for the distinction without supposing that "Aristotle" is rigid, whereas "the last great philosopher of antiquity" is not. According to Dummett, all that the distinction between (16) and (17) demonstrates is that there is a *syntactic* constraint on terms such as "Aristotle," which forces them to take wide scope with respect to modal operators.

Here is how Dummett's positive doctrine accounts for the distinction between (16) and (17). (17) and (the true reading of) (16), properly regimented (and abstracting from irrelevant detail), come out, on Dummett's view, as:

(16′) For some x such that Aristotle = x [$\Diamond$ x ≠ the last great philosopher of antiquity]
(17′) For some x, y such that Aristotle = x and Aristotle = y [$\Diamond$ x ≠ y]

(16′) is true because there are possible situations in which the actual denotation of "Aristotle" died as a child; whereas, given the rigidity of variables, (17′) is false. Thus, Dummett's positive doctrine accounts for the distinction between (16) and (17) without postulating a semantic difference between proper names and definite descriptions. Indeed, if Dummett's positive doctrine is correct, proper names can be identified with definite descriptions which take an obligatory wide scope with respect to modal operators.

On Kripke's account, the difference between (16) and (17) is attributed to a difference in the semantic values of the expressions "Aristotle" and "the last great philosopher of antiquity." (17) has no true reading because "Aristotle" is rigid; that is, it is associated with a (perhaps partial) constant function from worlds to objects, whereas (16) does have a true reading, since "the last great philosopher of antiquity" is not rigid; that is, it is associated with a non-constant function from possible worlds to objects. On Dummett's account, no difference in semantic value is required in order to explain the distinction between (16) and (17). It is simply a syntactic feature of proper names that they take wide scope with respect to modal operators; but, in all semantic respects, proper names are like descriptions.

However, Dummett's positive account is problematic, as the following argument by Kripke demonstrates. Suppose "t" is an expression which Kripke would classify as rigid, and "t′" is a non-rigid description which, according to Dummett, has the same content as "t." Consider now the following discourse:

(20) t is t. That's necessary.
(21) t is t′. That's not necessary.

Both (20) and (21) are true, given that "t" is an expression which Kripke would classify as rigid and "t′" is not rigid. But on Dummett's account, it is difficult to see how this could be so.

The central issue in interpreting this discourse is what the content of the occurrence of 'that' is. There are two possibilities. First of all, the occurrences of 'that' might refer to some 'value' of the preceding sentences, either the proposition it expresses ('what it says'), or some other semantic feature. The second possibility is that the occurrence of 'that' refers to the preceding sentences themselves, that is, it is replaceable by a quote-name of the preceding sentences. In each case it is difficult to see how Dummett's account could make both (20) and (21) true.

Suppose the first of these possibilities to be the case. That is, suppose that the occurrence of 'that' in (20) denotes some value of the preceding sentence 't is t.' Then, since both discourses are true, by Leibniz's Law, the value denoted by the occurrence of 'that' in (20) must be different from the value denoted by the occurrence of 'that' in (21), since the values have different properties (one is necessary, while the other is not). But Dummett's positive doctrine gives us no explanation of this fact. According to Dummett, one can explain rigidity facts by a syntactic stipulation that certain terms – those which Kripke classifies as rigid – take an obligatory wide scope with respect to modal operators. But no such operators occur in the initial sentences of (20) and (21). Therefore, Dummett's positive account predicts that there should be no differences in semantic value between these two sentences. But if the two occurrences of 'that' denote some semantic value of the preceding sentences, then the two sentences are associated with different semantic values, *contra* the predictions of Dummett's positive account.

So let us suppose, then, the second of the above possibilities to be the case; that is, suppose that the occurrence of 'that' in (20) denotes the sentence, "t is t." Similarly, suppose that the occurrence of 'that' in (21) denotes the sentence, "t is t′." In this case, we could replace the second sentences in (20) and (21) by:

(22) "t is t" is necessary.
(23) "t is t′" is not necessary.

(22) and (23) are true. But again, on Dummett's positive account, it is not possible to see how this could be the case. For there is no way for any of the occurrences of the term "t" to take wide scope with respect to modal operators, since they all occur within quotation marks.[40]

What Kripke's argument seems to show is that no syntactic account of the distinction between proper names and definite descriptions is possible. Thus, the difference between proper names and definite descriptions must be attributed to a difference in the semantic values they receive. Indeed, one might use this argument of Kripke's to establish RT. For even in the case of unmodalized sentences, replacing a rigid designator by a non-rigid designator

will typically result in a sentence which differs in truth-value in some possible world. One can exploit this to provide an argument for RT.

To see this, consider the following discourses, both true:

(24) Aristotle was not a philosopher. That would be true in a situation in which Aristotle died as a baby.
(25) The last great philosopher of antiquity was not a philosopher. That would not be true in a situation in which Aristotle died as a baby.

Using the same reasoning as in Kripke's argument, it follows that the sentences "Aristotle was not a philosopher" and "The last great philosopher of antiquity was not a philosopher" must have different semantic values. For one value, when evaluated with respect to a situation in which Aristotle died as a baby, is true, while the other, when evaluated with respect to that same situation, is not true. Thus, since the values have different properties – one is true with respect to the world in question, while the other is not true – by Leibniz's Law they must be different.

What this argument of Kripke's establishes is that whatever it is that is evaluated with respect to different metaphysically possible worlds in the case of "Aristotle was not a philosopher" differs from whatever it is that is evaluated with respect to different metaphysically possible worlds in the case of "The last great philosopher of antiquity was not a philosopher." Furthermore, it is clear that similar demonstrations can be given for other cases in which a non-rigid description might seem to have the same content as a rigid designator.

But RT might still seem worrisome. According to RT, sentences containing definite descriptions have different contents from the sentences which result from replacing those definite descriptions by any rigid expressions, even when the sentences are unmodalized. But there are *prima facie* counter-examples to this. For example, the sentences:

(26) The president of the USA came to dinner.
(27) The actual president of the USA came to dinner.

do not, on the face of it, seem to say different things; rather, the difference between utterances of (26) and (27) seems to lie in their pragmatic force. Yet "the president of the USA" is non-rigid, and "the actual president of the USA" is rigid.

Furthermore, (26) and (27) pose a problem for Kripke's argument in this section. For (26) and (27) differ in truth-value with respect to some metaphysically possible worlds. Utterance (26) is true in a world in which George Bush came to dinner, Bill Clinton did not, and George Bush won the 1992 election. Utterance (27) is not true with respect to such a situation. But it seems over-hasty to conclude from this that utterances of (26) and (27) say different things.

Examples such as (26) and (27) might lead one to the view that the semantic differences between rigid and non-rigid expressions do not imply that they must differ in content, as well as to the thesis that the differences in modal semantic value – that is, whatever is evaluated in other possible worlds – do not necessarily lead to a difference in content. Yet these reactions presuppose a distinction between semantic value and content which requires greater explication before it can be developed into a serious response to RT. It is to this task which we now turn.

7 Assertoric Content and Ingredient Sense

In this section, I will introduce and motivate Dummett's distinction between assertoric content and ingredient sense. I will then use this distinction in briefly suggesting a line of critique against RT.

The *assertoric content* of an utterance of a sentence is what is said by that utterance; it is also the object of belief, doubt, and other propositional attitudes. (See Chapter 14, PROPOSITIONAL ATTITUDES.) Assertoric contents are the fundamental bearers of truth-value. They are not true or false relative to a time or a place. Mary's belief that the sun is shining is not true at some times, false at others. What Mary says when she says that the sun is shining is not true in America, false in Australia. It is true or false, as Frege says, *tertium non datur*.

The *ingredient sense* of a sentence is what that sentence contributes to more complex sentences of which it is a part. The ingredient sense of a sentence is thus that sentence's compositional semantic value. It is the semantic value we must assign to a sentence in order to predict correctly the conditions under which more complex constructions in which it occurs are true. As Dummett notes, ingredient sense is what formal semantic theories are concerned to explain.[41]

Once one makes the distinction between ingredient sense and assertoric content, the possibility arises that the ingredient sense of a sentence might differ from its assertoric content. There are several ways in which this possibility might be realized. First of all, it could be the case that sentences which have the same assertoric content nonetheless contribute different things to more complex sentences containing them.[42] That is, it could be the case that sentences with the same assertoric contents have different ingredient senses. Second, it could be the case that the ingredient sense of a sentence cannot serve as its assertoric content, because it is not the sort of object which is fit to be believed or asserted. As we shall soon see, both of these situations in fact obtain.

Consider, first, the former of these possibilities, that is, that two sentences which have the same assertoric content differ in ingredient sense. Each of (29)–(31) has the same assertoric content as (28):

(28) The president is Bill Clinton.
(29) The current president is Bill Clinton.
(30) The president here is Bill Clinton.
(31) The actual president is Bill Clinton.

The difference between each of (29)–(31) and (28) is not truth-conditional, but pragmatic. In each of (29)–(31), a presupposition is present which is not present in (28).

But these presuppositions are cancelable. The sentences can be true, even if the presuppositions fail. Indeed, in any context c, an utterance of each of (29)–(31) is true in c just in case an utterance of (28) is true in c. On a natural construal of the expression "truth-condition," each of (29)–(31) has the same truth-conditions as (28), and hence has the same assertoric content as (28).

However, as the following sentence-pairs demonstrate, the two sentences in each of the sentence-pairs have different *ingredient senses*:

(32) It will always be the case that the current president is Bill Clinton.
(33) It will always be the case that the president is Bill Clinton.

(34) Everywhere, it is the case that the president here is Bill Clinton.
(35) Everywhere, it is the case that the president is Bill Clinton.
(36) Necessarily, it is the case that the actual president is Bill Clinton.
(37) Necessarily, it is the case that the president is Bill Clinton.

In each of these sentence-pairs, the first sentence is true, but the second false. Thus, each of (29)–(31) contributes different things to more complex sentences of which they are a part than (28). But then, given that utterances of them have the same assertoric content as utterances of (28), we have shown that utterances of two sentences can have the same assertoric content, while nonetheless differing in ingredient sense.

Consider now the second of these possibilities, namely that ingredient senses are not the sort of objects which can be identified with assertoric contents, things believed and asserted. As the following examples show, and as Lewis (1981) points out, this too is the case:

(38) It will be the case that the sun is shining.
(39) Somewhere, the sun is shining.
(40) In the future, there might be a miracle somewhere.

In each case, what the embedded sentence contributes to the interpretation of the whole sentence is not something which could plausibly be identified with an assertoric content, something fit to be believed or asserted. In the case of (38), the embedded sentence "the sun is shining" must express a function from times to truth-values. In the case of (39), the embedded sentence must express a function from places to truth-values. Finally, in the case of (40), the embedded sentence must express a function from world, time, and place triples to truth-values.

But, as we have seen, functions from times or places to truth-values are not fit to be things believed or asserted. Mary's belief that the sun is shining does not vary in truth-value from one time to another, or from one place to another. It is true or false, *tertium non datur*. Therefore, ingredient senses are not fit to be assertoric contents.[43]

Let us now sum up our conclusions so far in this section. First, we have seen that sentences can have the same assertoric content, while differing in ingredient sense. Second, we have seen that ingredient senses are not the sort of objects which can be regarded as assertoric contents. Keeping these facts in mind, let us now turn to how these facts bear on RT.

In the original argument for RT, we inferred, from the fact that "Aristotle is Aristotle" and "Aristotle is the last great philosopher of antiquity" embed differently in modal contexts – that is, (16) and (17) differ in truth-value – that the two sentences have different contents, and hence that "Aristotle" and "the last great philosopher of antiquity" have different contents. Yet, once the assertoric-content/ingredient-sense distinction is made, it is clear that this sort of inference is invalid. From (16) and (17), it is only legitimate to infer that "Aristotle is Aristotle" and "Aristotle is the last great philosopher of antiquity" have differing ingredient senses. Similarly, it is only legitimate to infer from (16) and (17) that "Aristotle" and "the last great philosopher of antiquity" have different semantic values. But as we have seen, this does not demonstrate that replacement of one with the other typically yields a sentence with a different assertoric content. That is, such facts as (16) and (17) do not demonstrate the truth of RT.

But what about the Kripkean argument for RT given in the last section? In the case of (20) and (21), and (24) and (25), the initial sentences were not embedded in modal

contexts. Nonetheless, the Kripkean argument established that the sentence containing the rigid designator, and the sentence resulting from it by replacing the rigid designator by a non-rigid designator, corresponded to different values. However, the Kripkean argument only demonstrates RT if the values in question are assertoric contents, or propositions, rather than ingredient senses. For, as we have seen, it is perfectly possible for two sentences to differ in ingredient sense, yet for utterances of them to have the same assertoric content.

The fundamental question in evaluating the Kripkean argument is what the denotations of the occurrences of 'that' are in the relevant discourses. If such occurrences of 'that' denote the assertoric content of the preceding sentences, then the argument does indeed demonstrate RT. If, however, such occurrences of 'that' denote the ingredient senses of the preceding sentences, then the argument only demonstrates that the preceding sentences differ in ingredient sense, a fact perfectly consistent with their coinciding in assertoric content.

Now, there is no question that such occurrences of 'that' can denote the assertoric content of the occurrences of the preceding sentences. This is precisely what the denotation of 'that' is in such contexts as:

(41) The sun is shining. That's asserted by John.
(42) The sun is shining. That's believed by Mary.

Our question is thus: do all such uses of 'that' denote the assertoric contents of the occurrences of the preceding sentences, or do they sometimes denote the ingredient senses of the preceding sentences?

That the latter is the case can be seen from the following two examples:

(43) The sun is shining. That will be true, but it isn't true now.
(44) The sun is shining. That's true somewhere, but it isn't true here.

In order for (43) to be true, the occurrence of 'that' must denote a function from times to truth-values. Similarly, in order for (44) to be true, the occurrence of 'that' must denote a function from places to truth-values. But, as we have seen, such entities are certainly not assertoric contents, things believed and expressed. Such examples hence show that some such occurrences of the word 'that' denote the ingredient senses, rather than the assertoric contents, of the preceding sentences.[44]

The fact that the word 'that' sometimes denotes the ingredient sense, rather than the assertoric content, of the preceding sentence allows the Dummettian to respond to the Kripkean argument as follows. What she would maintain is that the occurrences of 'that' in (20), (21), (24), and (25) denote, not the assertoric content of the preceding sentences, as in the occurrences of 'that' in (41) and (42), but rather the ingredient sense. Since a difference in ingredient sense does not imply a difference in assertoric content, the Kripkean argument fails to demonstrate RT.

For the Dummettian, then, the Kripkean argument fares about as well as the following argument for the thesis that utterances of (28) and (29) always have different assertoric contents:

(45) The current president is Bill Clinton. That will always be true.
(46) The president is Bill Clinton. That won't always be true.

It would be over-hasty to conclude, from this argument, that utterances of (28) and (29) must have different assertoric contents.[45] Similarly, according to the Dummettian, it would be over-hasty to conclude, from (20) and (21) alone, that "t = t" and "t = t′" have different assertoric contents.

What a friend of RT must show is some disanalogy between the argument from (20) and (21) to the conclusion that "t is t" and "t is t′" do not have the same assertoric content, and the argument from (45) and (46) to the conclusion that (28) and (29) have different assertoric contents. There are two ways in which she could proceed. First, she could argue that, in modal contexts, the relevant uses of 'that' do denote the assertoric contents of the preceding sentences. Alternatively, she could argue that, unlike the case of (45) and (46), a difference in the particular ingredient sense, or semantic value, denoted by these occurrences entails a difference in assertoric content.

According to the opponent of RT, the object of modal evaluation, like the object of temporal evaluation, is not a proposition or assertoric content. To make her position clear, she must first provide some clear account of the assertoric-content/ingredient-sense distinction. Then, she must provide an account of assertoric content which distinguishes it in relevant ways from the object of modal evaluation.[46]

Conclusion

As we have seen, given the possibility of actualized descriptions, there is no argument from rigid designation against the description theory of names. The more interesting question, however, is the status of RT. What I have tried (ever so briefly) to motivate is the view that RT is not as innocent as many philosophers believe. The classic Kripkean argument in its favor fails. That is not to say that RT is false: for instance, it may be that the best theory of content entails it.[47] On the other hand, there may be substantive empirical or methodological objections against it. But I am afraid that these are issues which we must leave for future philosophy of language to decide.[48]

Notes

1 This characterization of rigidity is from a letter from Kripke to Kaplan, cited on p. 569 of Kaplan's "Afterthoughts" (1989b).

2 There is another notion of rigidity occasionally suggested in the literature according to which a term is rigid just in case it refers to the same object in all possible worlds in which it refers at all. But this is consistent with the actual denotation of a rigid designator existing in some possible world, yet unnamed by that designator. This possibility is ruled out by Kripke's general characterization of rigidity. In what follows, "rigidity" will instead be used in accordance with Kripke's general characterization.

3 Besides the issues that will be discussed in later sections, there are other issues in philosophical logic which may push one to prefer one or the other characterization of rigidity. For instance, if one defines necessity as truth in every world, then, to capture the intuitive necessity of "Bill Clinton = Bill Clinton," one might wish to allow "Bill Clinton" to denote Bill Clinton with respect to every possible world (in which case one would prefer the characterization of rigidity as obstinate rigidity). Alternatively, one could exploit another notion of necessity, *viz.* non-falsity in every world. This would allow "Bill Clinton = Bill Clinton" to lack a truth-value in some possible worlds without thereby becoming contingent, hence removing the need to treat designators as obstinately rigid to preserve the necessity of "Bill Clinton = Bill Clinton." Similar issues arise with respect to

the characterization of validity. However, here, too, it is difficult to see any substantive issues. As Kripke (1963, p. 66) writes, "For the purposes of modal logic we hold that different answers to [these questions] represent alternative *conventions*. All are tenable."

4 However, eliminating the metaphor of mediation in the characterization of this distinction is no easy task. Furthermore, as will become clear in later sections, it is unclear how the distinction between *de jure* and *de facto* rigid designation generalizes to other expressions.

5 Because of space considerations, I will not discuss the latter's use of substitutional quantification in explicating quantification into modal context.

6 For discussions of Quine's objections, see Fine (1989) and Kaplan (1986). See also Richard (1987). There is a substantial body of contemporary literature on this topic.

7 So perhaps it is not really correct to call these two different objections.

8 I am here, as below, *not* using "objectual" in the sense of the distinction between objectual and *substitutional* quantification, but rather in the sense of the soon-to-be-explicated distinction between quantification over individuals versus quantification over concepts.

9 Here, "a" and "b" and "φ" are being used as schematic letters replaceable by metalinguistic names for object language expressions, and "' is being used for quasi-quotation. I will use "' as normal quotation and quasi-quotation, leaving it to context to disambiguate. In general. I will be lax about use/mention.

10 Kaplan (1986) calls this "Quine's Theorem." See pp. 231–238 for a reconstruction of Quine's (1943) arguments, and Kaplan's critique of it. See also Fine (1989).

11 It is illegitimate *simpliciter* to quantify into contexts in which the quotation is ordinary English quotation. However, Kaplan (1986) introduces a new quotation device, which he called "arc quotes," and showed how to make sense of quantification into them (see §§7 ff.).

12 Furthermore, on the conceptual interpretation of QML, there are ways to rescue substitution of co-extensional expressions in extensional contexts, and even to rescue a quantified version of extensional substitution of the form:

(*) $\forall x \forall y\,(x = y \rightarrow (\varphi \leftrightarrow \psi))$

(where φ differs from ψ in containing free occurrences of 'x' where ψ contains free occurrences of 'y', and φ and ψ are extensional). According to Carnap, for example, both terms and variables are systematically ambiguous. To each term, there corresponds both an extension and an intension (something which yields, at every possible world, an extension). In addition, to each variable, there correspond both *value extensions* and *value intensions.* The value intensions of a variable are the set of intensions of expressions which are admissible substitution instances of that variable, and the value extensions are the set of extensions of expressions which are admissible substitution instances of that variable (see Carnap, 1988, §10). Since in extensional contexts all that is relevant are the value-extensions of variables and the extensions of terms, once the notion of "extensional context" has been appropriately inductively defined (say, as a wff of non-modal first- or higher-order calculus), both the fully schematic version of extensional substitution and the version of substitution containing quantifiers can be preserved. This is Carnap's "Method of extension and intension" (1988, ch. 1). Church avoids having to give expressions and variables a double interpretation, choosing instead to follow Frege in relativizing their interpretations to contexts. For a discussion of these matters, see Fine (1989, pp. 267 ff.). For an old attack on the *metaphysical* coherence of the conceptual interpretation, see Quine (1947).

13 For simplicity's sake, I am speaking here only of non-vacuous existential quantifications into modal formulas with one free variable (so it is appropriate to speak of truth and falsity, rather than satisfaction). I will occasionally make such simplifying assumptions without comment.

14 Of course, such a primitive relational sense of necessity is analogous to Quine's (1956) primitive relational sense of propositional attitude verbs. Quine himself later noticed (1977) that his reconstruction of quantification into propositional attitude contexts could be used in this way to defend the coherence of quantification into modal contexts.

15 Here, "exists" is a primitive predicate which is true of an object with respect to a possible situation just in case that object is in the domain of the possible situation.

16 Missing this point, Quine (1977, p. 8) asserted that the notion of rigidity by itself presupposes the notion of an essential property: "A rigid designator differs from others in that it picks out its object by essential traits." A careful reading of Kripke's discussions of transworld identification (e.g., 1980, p. 44) might have dispelled his belief in this.

17 This is for non-complex terms. If the language contains rigid complex terms – rigid descriptions – the interpretation of terms which are not variables may, of course, depend upon an assignment function.

18 For instance, even the free-logical rule of universal instantiation can fail for languages with non-rigid terms (cf. Garson, 1984, pp. 262–263). Furthermore, the introduction of non-rigid terms complicates completeness proofs for systems of QML, since standard completeness proofs rely on substitution facts (cf. Garson, 1984, pp. 287–289).

19 In retrospect, the latter option seems only to be motivated if one accepts Quine's rather curious idolatry of classical quantification theory. There are many ways of restricting classical substitution to account for non-rigid terms, either by restricting substitution to atomic formulas, or by reformulating quantification theory in terms of complex predicates and restricting substitution to complex predications (for this latter option, see Robert Stalnaker, 1977; 1995). See also, for a development of the appropriate proof theory for a language with complex predicates and non-rigid designators, Fitting (1993, §3; 1991).

20 For instance, Arthur Smullyan (1947; 1948) argued, against Quine's logico-semantical objection to QML, that once one recognizes that descriptions are to be treated on Russellian lines, rather than as terms, then Quine's objection fails. Smullyan is thus the first person explicitly to suggest that natural-language terms are such that classical substitution holds for them. However, since Smullyan wrote years before Kripke's development of the semantics of QML, he cannot be credited with the discovery that natural-language names are rigid, since he did not possess the resources to define the notion of rigidity. Furthermore, he provided no argument to the effect that natural-language terms are rigid. A similar point holds for Barcan Marcus. Though she derived (quantified) versions of the necessity of identity (Barcan 1947; see esp. theorem 2.32), she did not, at that time, have the notion of rigidity, since she had neither an explicit semantics in mind, nor any sort of philosophical or semantic argument about natural language. She does suggest (1961) that natural-language names are mere "tags" for objects, but she neither provides the sort of arguments required for the establishment of this thesis, nor possesses the semantical apparatus necessary to characterize the notion of rigidity. Nonetheless, the work of Smullyan, Barcan Marcus, and also Frederick Fitch certainly provided much of the necessary impetus for the later development of these notions. For an excellent discussion of their role in the history of the notion of rigidity, see Scott Soames (1995).

21 For instance, for Strawson, descriptive identification is based upon demonstrative identification:

> [The supposition that where the particular to be identified cannot be directly located, its identification must rest ultimately on description in general terms] is false. For even though the particular in question cannot itself be demonstratively identified, it may be identified by a description which relates it uniquely to another particular which can be demonstratively identified. (1959, p. 21)

Nonetheless, for Strawson's anti-skeptical arguments to succeed, he must be assuming that successful reference requires uniquely identifying knowledge given by description. Dummett directly challenges the thesis that for Frege, the sense of each proper name can be given by a description (see, to cite one example, the appendix to ch. 5 of his 1981a). For Frege, his belief that a change in reference entails a change in sense demonstrates that he did not ascribe to the "description in general terms alone" account.

22 The case is more difficult in the case of "I" and "here," for their reference is "guaranteed." See Evans (1982, chs 6 and 7) for an attempt to fit an account of these words into a model more closely paralleling perceptual demonstratives than seems, *prima facie*, to be possible, and see Lucy O'Brien (1995) for a recent critique of Evans's account.

23 Though see Kripke (1980, p. 58) for a challenge to this paragraph.

24 This distinction between different descriptive pictures of intentionality is relevant for Kripke's epistemological critique of descriptive theories of intentionality, though not his argument from rigidity.

25 Of course, to bring this fully in line with the description theory, we would also have to analyze the place name "the United States."

26 Furthermore, I will use "possibilist" quantifiers (that is, quantifiers whose domains are not restricted to worlds, but rather range over all actual and possible objects) as well as a primitive existence predicate ("x exists") which is true of an object at a world just in case that object is in the domain of that world (i.e., exists in that world).

27 See, for example, Allan Gibbard's discussion (1975) of "Goliath" and "Lumpl."

28 To rescue the necessity of identity, one would be forced to reformulate some clause in the semantics. One method is to replace the identity axiom schema by its free-logical counterpart. Alternatively, one could redefine the necessity operator, as in, for instance, van Benthem (1983, ch. 12, pp. 136–137), to restrict evaluation of the embedded sentence to worlds at which there exist the denotations of constants in the sentence, and values of the free variables of the sentence.

29 See Montague (1974, p. 126). This example, too, is not fully convincing, since "remembers" is intensional. A slightly better example is "Aristotle is currently the most-read philosopher."

30 Cf. Salmon (1982, pp. 37–39) for a longer discussion. Evans (1985a) has challenged the analogy between tense and modality.

31 That is, (17) has no true reading where the possibility in question is *metaphysical* possibility. Throughout, all occurrences of modal expressions should be read as expressing metaphysical possibility.

32 Kripke's argument that the content of a proper name is only its denotation depends more on the epistemological arguments he gives in Lecture II (1980). We will not discuss these arguments here.

33 This is only a rough statement of the actual thesis. For one may have a coarse-grained account of content, where, say, logical contradictions say the same thing. In this case, utterances of sentences which express logical contradictions, such as "John is tall and it is not the case that John is tall," would say the same thing as utterances of sentences with the name replaced by a non-rigid designator. But this is obviously not an objection to Kripke, for if such an account of content is endorsed, then the statement of the rigidity thesis would have to be modified to capture more adequately Kripke's intention.

34 Formally, the logic of the sentential operator "actually," which is the modal logic analogue of the temporal indexical "now," has been much investigated. Classic papers in this area include Segerberg (1973), Davies and Humberstone (1980), and Hodes (1984a; 1984b). For recent books on the subject, see Graeme Forbes's excellent (1989), which uses rigidifying operators such as "actually" to dispense with quantification over (and hence ontological commitment to) possible worlds, as well as Max Cresswell (1990) for an argument against a Forbes-like position.

35 However, if one characterizes the notion of *de jure* rigidity in terms of an expression being rigid "in virtue of the semantical rules of the language," then, given that the semantical rules of the language state that "actual" is a rigidifying operator, actualized descriptions *will* count as *de jure* rigid designators (cf. Almog, 1986, pp. 223 ff.). If *de jure* rigidity is so characterized, then the *de jure/de facto* distinction is simply irrelevant to the question of whether names have descriptive content.

36 However, Kaplan does add qualifications (1989a, p. 497).

37 See also, in this context, Kripke's discussion of "Cicero" and "Jack the Ripper" in (1980, p. 79). For an interesting challenge to the whole idea of a descriptive name, see Bostock (1988).

38 To make issues of rigidity relevant for arguments against descriptive accounts of content, one needs to argue that proper names are, in the sense of Evans (1985b), *deeply rigid designators*, where an expression e counts as a deeply rigid designator of an object o just in case, for every possible world w, e refers to o when considered as *uttered in w*. Actualized descriptions are thus not deeply rigid designators. There are few attempts to address the question of whether names are deeply rigid; though see Deutsch (1989). Thanks to Sanford Shieh for discussion here.

39 See, for example, the appendix to ch. 5 of Dummett (1981a), appendix 3 of his (1981b), and ch. 2 of his (1991). The arguments outlined in the final two sections have their sources in these passages.

40 There is a third possibility, that is, that the occurrences of 'that' are unstructured names of the preceding sentence-tokens. But in this case it is even more difficult to see how "t" could take wide scope with respect to the modal operator in the next sentence. The only way I can see to defend Dummett's positive account is by using Kaplan's (1986) device of "arc quotes," maintaining that the "that" is replaceable by arc-quote names of the preceding sentences, which do license quantifying in.

41 See Dummett (1991, p. 48). By "formal semantic theory," I mean the project Robert Stalnaker calls "descriptive semantics" (see Chapter 35, REFERENCE AND NECESSITY).

42 I have characterized assertoric content as applying primarily to utterances rather than to sentence-types. But we can, from this characterization, obtain an equivalence relation of sameness of assertoric content which holds between sentence-types. Say that two sentence-types, S and S′, have the same assertoric content, just in case, for every normal context c, utterances of S and S′ in that context have the same assertoric content (for the notion of "normal context," see §I of my (1997)).

43 This is precisely Lewis's central conclusion (1981), albeit phrased in terms of Dummett's distinction between assertoric content and ingredient sense, rather than Lewis's vocabulary of "proposition" versus "semantic value" (1981, p. 95). Some of these facts have also been recognized (though used for different purposes) by Richard (1981; 1982) and Salmon (1986, ch. 2).

44 Ordinary language examples can, however, occasionally mislead here. For instance, the sentence "John believes something that was true yesterday, and false today" is perfectly acceptable. Yet the existence of such examples should not be taken as undermining the philosophical position that the objects of belief must be true or false absolutely. Such examples can be dealt with, as in Forbes (1989, p. 163), by interpreting the quantification substitutionally.

45 Similarly:

(a) The sun is shining. That's true now, but it won't be true tomorrow.
(b) The sun is shining. That's true here, but it's not true in Scotland.

46 According to Forbes (1989, part II), whereas assertoric contents are to be identified with Fregean thoughts, states of affairs are the objects of modal evaluation. My own view (Stanley, 1997) is that modal semantic value comes from the speech act of supposition, rather than assertion.

47 The classical 'Russellian proposition' view of content, for example, Kaplan (1989), Salmon (1986), and Soames (1987), is one view which entails RT.

48 Robert Stalnaker and Timothy Williamson deserve the greatest thanks for helping me with this chapter. In addition, extensive comments by Bob Hale and Crispin Wright substantively improved the chapter. I would also like to thank Michael Dummett, Kit Fine, Richard Heck, and Susanna Siegel for discussion.

Two-Dimensional Semantics

CHRISTIAN NIMTZ

1 2D Semantics: Ideas, Interpretations, and Issues

The theories that form the heterogeneous family of two-dimensional or 2D semantics are rooted in the tradition of possible-worlds semantics made popular by Saul Kripke and David Lewis. This semantics recognizes a *dependence of truth on fact*. Consider the sentence 'Pavarotti is famous.' Its truth-value depends on how things are. If things are as the sentence says, it is true; if they are not, it is false. A semantics may thus capture the truth-conditions of the sentence by specifying how its truth-value varies with the ways things could be. Equating ways things could be with possible worlds, we arrive at a core idea of intensional semantics – the idea that the truth-conditions of a sentence are (or weaker: can be modeled as[1]) its truth-values at all possible worlds. This idea generalizes. We can equate the semantic value of any expression with an intension, that is, a function from possible worlds to extensions, be it an individual (as in the case of singular terms), a set (as in the case of predicates), or a truth-value (as in the case of sentences).

Advocates of 2D semantics agree that recognizing a dependence of truth on fact is not enough. They urge us to acknowledge another dependence, which I, with deliberate looseness, call the *dependence of truth on meaning-fixing conditions*. Proponents of 2D accounts thus agree that the extensions of our expressions are doubly dependent on meaning-fixing conditions *and* on the respective facts – although they fervently disagree on what the former dependence amounts to.

Here is a way to motivate this idea. Suppose Pavarotti utters 'I am famous.' The truth-value of this indexical utterance at a possible world *w* depends on whether or not Pavarotti is famous at this world *w*. Yet its truth-value also depends on who made the utterance in the first place. Here we have a double dependence of the truth-value of an utterance at a world *w* on the facts in *w and* on the relevant content-fixing conditions – on whether or not Pavarotti is famous, and on who made the utterance in the first place.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

Advocates of two-dimensional semantics share a second trademark idea. They agree that the familiar apparatus of worlds-cum-intensions can be modified so as to capture both the dependencies they see. The resulting 2D apparatus discerns a first or 'A-dimension' of possible worlds playing the role of meaning-fixing conditions from a second or 'C-dimension' of possible worlds standing in as the relevant facts – hence *two*-dimensionalism.[2] It moreover assigns intensions in a way that captures the double dependence of extension on relevant facts and meaning-fixing situations.

Two-dimensional theories and ideas have influentially been proffered by David Kaplan (1977; 1989), Robert Stalnaker (1978; 2004), Gareth Evans (1979), Davies and Humberstone (1980), David Lewis (1980), Frank Jackson (1998; 2004; 2010), and David Chalmers (2002a; 2004; 2006). 2D semantics has been inspired by more formally oriented work in two-dimensional logic such as, for example, Åqvist (1973), Segerberg (1973), and van Fraassen (1977); see Kuhn (2012) and Humberstone (2004) for an overview. The diverse 2D accounts share little beyond the characteristic formal apparatus of worlds-cum-intensions that results from their trademark ideas. One reason for this is quite clear. Advocates of 2D semantics take different attitudes on what I dub 'orthodox Kripkeanism.'

Orthodox Kripkeans maintain that Kripke is right in his semantical doctrines concerning rigid designation and necessities *a posteriori*, and that he is right in his meta-semantics[3] leading to an anti-Fregean picture of reference and communication. Advocates of 2D semantics as a rule accept Kripke's semantic doctrines. (David Lewis is a notable exception to this.) They expect a semantics to make good on Kripkean claims such as, say, that 'Venus' designates rigidly, or that 'Water is H_2O' is necessary *a posteriori*. However, advocates of 2D theories take different attitudes towards Kripkean meta-semantics. There are prominent 2D theorists, such as David Kaplan and Robert Stalnaker, who embrace the orthodox Kripkean picture of reference and communication and employ 2D techniques in order to add to it. I will call anyone who likewise employs 2D techniques a '2D Kripkean.' Other 2D theorists, most notably Frank Jackson and especially David Chalmers (see also Davies and Humberstone, 1980), enlist 2D ideas to reject Kripkean meta-semantics. Jackson and Chalmers accept rigid designation and *a posteriori* necessities. But they reject Kripkean meta-semantics in favor of a Fregean, sense-based theory leading to a substantially different picture of reference and communication. I will call everyone who likewise employs 2D techniques a '2D Fregean.'[4]

Often somewhat misleadingly labeled 'two-dimensionalism,' the revisionist 2D Fregean program of Jackson and Chalmers has far-reaching implications for meta-philosophy and metaphysics. Jackson and Chalmers embrace a meta-philosophical picture that assigns conceptual analysis center stage (see Jackson, 1998). They can do so because their 2D Fregeanism allows for conceptual analysis, whereas Kripkeanism is inimical to it – if the semantic properties of, say, 'belief' are fixed causal-historically, there is little point in mulling over the concept in the armchair if you want to ascertain truths about beliefs.[5] This is presumably why the contemporary debate focuses on 2D Fregeanism, rather than on 2D semantics more broadly conceived (see García-Carpintero and Macià, 2006; Soames, 2005, and the contributions to the 2004 *Philosophical Studies* (118:1) volume on 2D semantics). In fact, much of the debate concerns two issues:

- Can 2D Fregeans devise a compelling semantics that is fundamentally Fregean, yet respects Kripke's semantic insights, and accommodates Kripke's arguments widely assumed to show that any sense-based account fails for proper names and natural kind terms?
- Is there any need for a 2D Fregean revision of orthodox Kripkeanism to begin with?

Within the philosophy of language, there is comparatively little controversy about the 2D accounts of Kaplan and Stalnaker. The former, especially, appears to be widely accepted as a standard semantics of indexicals.

2 The 2D Apparatus of Worlds-cum-Intensions

The commitments of all 2D theories can basically be captured by one and the same formal framework of worlds-cum-intensions. I call it 'the 2D apparatus.' To understand the 2D apparatus, then, is to understand the general structure that all 2D accounts share.

In order to capture the dependence of truth on fact, traditional intensional semantics assigns every expression an intension, that is, a function *f*: $W \rightarrow E$ from worlds to extensions, as its semantic value. Consider the sentence 'Pavarotti is famous.' Its intension is a function *f*: $W \rightarrow$ {*true*, *false*} from worlds to truth-values such that the sentence gets assigned the truth-value *true* at a world *w* just in case Pavarotti is famous in *w*. This intension is determined by the intensions of the name and the predicate the sentence comprises. The intension of the name 'Pavarotti' is a function *f*: $W \rightarrow$ D from worlds *w* to individuals (intuitively: the individual that is Pavarotti in *w*), and the intension for 'is famous' is a function *f*: $W \rightarrow P$(D) from worlds *w* to sets of individuals (intuitively: the set of individuals famous in *w*).[6] Possible worlds here figure as counterfactual alternatives to our actual world, and they play the role of being what sentences are evaluated at for truth or falsity. Let us label worlds playing this role 'C-worlds.'

Proponents of two-dimensional semantics maintain that C-worlds are not enough. In order to capture the dependence of truth on meaning-fixing conditions, we need a prior dimension of worlds I call 'A-worlds.' To again use indexicals for illustration, consider Pavarotti uttering 'I am famous.' Call this utterance *u*. Whether *u* is true at some C-world *w* depends on the facts at *w*. Yet it also depends on who uttered *u* in the first place. Given that it was Pavarotti who produced *u*, *u* is true at some C-world *w* just in case Pavarotti is famous in *w*. If someone else uttered *u* instead, the truth-conditions of the utterance will vary accordingly. We thus find that the intension expressed by an utterance of 'I am famous' systematically depends on prior meaning-fixing conditions, or A-worlds: it depends on the context of utterance. There is a two-stage procedure at work. First of all, the context of utterance (= the A-world) fixes *u*'s truth-conditions. It depends on the respective A-world which specific function *f*: $W_C \rightarrow$ {*true*, *false*} from C-worlds to truth-values is *u*'s intension. That Pavarotti figured as the speaker in the context of utterance of *u* led to *u* having its specific intension. Second, given that *u* has this intension, it can be evaluated for truth or falsity by considering the relevant facts (= a C-world): *u* is true at some C-world *w* just in case Pavarotti is famous in *w*.

All two-dimensional semantics envisage such a two-step procedure of evaluation. They therefore distinguish A-worlds standing in as meaning-fixing conditions from C-worlds serving as the relevant facts. It is most natural (though controversial) to hold that the same possible worlds figure as A- and C-worlds, respectively; they just play different roles in these different capacities. There is one important exception to this. In order for the account to do the work it is supposed to do, A-worlds need to be *centered*, that is, they must come with a *center* consisting of a speaker (if any), an audience (if any), a place, a time, and so on, highlighted. (I throughout assume A-worlds to be centered. If need be, I use 'w^*' to emphasize that we are dealing with the world *w* with some arbitrary center marked.)

Second dimension
C-worlds →

First dimension
A-worlds (centered) →

	w1	w2	w3
w1*	t	t	f
w2*	f	t	t
w3*	t	t	f

Figure 37.1 The matrix specifies all three intensions of a sentence for a small sample of worlds. Every row specifies a C-intension. The diagonal specifies the A-intension. The matrix as whole specifies the 2D intension.

The resulting apparatus with its two dimensions of worlds allows us to distinguish three kinds of intensions. First of all, there are *C-intensions*. (Kaplan calls these 'contents'; Chalmers speaks of 'secondary' or '2-intensions.') A C-intension is a function f: $W_C \rightarrow E$ from C-worlds to extensions. A C-intension of a sentence δ specifies for any C-world w whether δ is true or false at w. Stalnaker dubs C-intensions of sentences 'horizontal propositions' since they corresponds to a row in the sentence's 2D matrix (see Figure 37.1). C-intensions are the intensions figuring in classic possible-worlds semantics.

Second, there are *A-intensions*. (Chalmers calls these 'primary intensions' or '1-intensions.') An A-intension is a function f: $W_A \rightarrow E$ from A-worlds to extensions. The A-intension of a sentence δ specifies for any A-world w whether, given that w figures as the meaning-fixing conditions for δ, δ is true or false when evaluated at the very same world w. Since the A-intension of a sentence corresponds to the diagonal in the sentence's 2D matrix (see Figure 37.1), Stalnaker dubs propositional A-intensions 'diagonal propositions.'[7]

Finally, there are two-dimensional intensions. (Kaplan speaks of 'characters.') The 2D intension of an expression α specifies for any A-world w which C-intension α has, given that w figures as the meaning-fixing conditions. 2D intensions thus are functions f: $W_A \rightarrow$ (f: $W_C \rightarrow E$) from A-worlds to C-intensions; alternatively, we can take them to be functions f: $W_A \times W_C \rightarrow E$ from pairs of A- and C-worlds to extensions. The whole schema given in Figure 37.1 specifies (part of) a 2D intension.

As emphasized above, advocates of 2D semantics agree that the apparatus of worlds-cum-intensions can be modified so as to capture both the dependencies they see. As should now be apparent, the modification consists in distinguishing A-worlds from C-worlds. It should also be apparent how the resultant 2D apparatus captures the dependence of truth on fact and the dependence of truth on meaning-fixing conditions (as well as the double dependence of truth on both). It does so by way of C-intensions, A-intensions, and 2D intensions, respectively.

The various 2D accounts tend to consider one of these intensions as fundamental, and the others as derivative. But on the face of it, it is a virtue of the general 2D schema that it encompasses all three kinds of intensions.[8]

First of all, discerning A- and C-intensions allows the 2D apparatus to account for conflicting pre-theoretic semantic judgments. Suppose Emma and Joe both utter 'I am fine.' Have they said the same thing? Intuitively speaking, yes and no. Both utterances are true

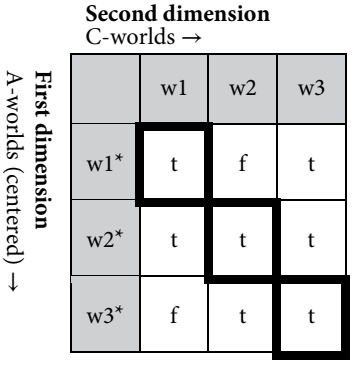

Figure 37.2 The matrix specifies (part of) the intensions of 'I am here.' It combines a necessary A-intension or diagonal with contingent C-intensions.

just in case the respective speaker is fine. They say the same thing by virtue of expressing the same A-intension. However, what Emma said is true just in case Emma is fine, whereas what Joe said is true just in case Joe is fine. So they do not say the same thing, by virtue of expressing different C-intensions.

Second, discerning A- and C-intensions allows us to account for an apparent modal puzzle. Suppose I utter 'I am here now.' To do so is to make a contingent claim. I could right now have been someplace else. However, I could not possibly have said something false with my utterance, and what could not possibly have been false is necessarily true. The 2D apparatus dissolves the tension. The utterance combines a contingent C-intension with a necessary A-intension. In Gareth Evans's (1979, p. 179) terminology, the statement is superficially contingent, yet deeply necessary. Generalizing, we may acknowledge two different modal dimensions and devise two different types of modal operators. For instance, we could rule that '$\Box\delta$' is true just in case δ's C-intension yields *true* for any C-world, whereas '$\boxdot\delta$' is true just in case δ's A-intension yields *true* for any A-world (see Kuhn, 2012, for details).

Finally, 2D intensions allow for a homogeneous account of semantic competence. The following three apparently innocuous ideas spell trouble once they are combined:

(i) Semantic competence concerns sentence-types.
(ii) To understand a sentence is to know its truth-conditions.
(iii) Sentence-types containing indexicals do not have truth-conditions, since indexical-types do not refer – there is no object the *type* 'I' refers to.

Here is a two-dimensional way to solve this puzzle. Let us trade (ii) for the idea that to understand a sentence is to know its 2D intension. This idea is natural enough for indexical sentence-types such as, for example, 'I am famous.' If the type 'I' does not refer, the sentence-type does not have truth-conditions. So my semantic competence cannot consist in knowing these. There still is something I know. I know which truth-conditions an utterance u of this sentence has, given that u occurs in a specific context (= A-world). My semantic competence with 'I am famous' can thus be captured by a 2D intension detailing a function f: $W_A \rightarrow (f\text{: } W_C \rightarrow E)$ from A-worlds to C-intensions. The same holds arguably and on some 2D accounts even trivially true of my competence with non-indexical sentence-types.

All varieties of 2D semantics employ basically the same 2D apparatus. There also is fundamental agreement on to how to understand the C-dimension. C-worlds are Kripke's

metaphysically possible worlds understood to be counterfactual alternatives to our actual world, and they are employed to capture the dependence of truth on fact. C-intensions are the intensions of traditional intensional semantics, and C-necessity is metaphysical necessity. There is no such consensus on the A-dimension; far from it. 2D Kripkeans like Kaplan and Stalnaker and 2D Fregeans like Jackson and Chalmers hold very different views on what the dependence of truth on meaning-fixing conditions amounts to, and why our semantics should capture it. Given the 2D apparatus, this is to say that they differ on what A-worlds are and why we need them, what A-intensions capture, and what A-necessity amounts to. A key reason for this is that these theorists take different attitudes on orthodox Kripkeanism.

3 Essential Background: Orthodox Kripkeanism

Orthodox Kripkeans, as I employ the term, embrace the key semantic and meta-semantic doctrines developed by Kripke (1971; 1980) and in work congenial to his (see Putnam, 1975; Burge, 1986; Kaplan, 1977). Orthodox Kripkeanism arguably is the presumed default position in much of contemporary semantics. It combines five doctrines of interest to us.

According to the first Kripkean doctrine, many of our terms designate rigidly. Glossing over intricacies (see Hughes, 2004, pp. 19–24), a term is a "rigid designator if in every possible world it designates the same object" (Kripke, 1980, p. 48). Kripkeanism considers proper names like 'Cicero' and natural kind terms such as 'gold' to be clear instances of rigidly designating expressions. Kaplan's work (see next section) has added indexicals such as 'today' to this list.

According to the second Kripkean doctrine, there are necessities *a posteriori*. Let us understand this idea modestly as stating that there are necessarily true yet *a posteriori* sentences. Read thus, the doctrine is agreeable to any self-proclaimed Kripkean. This does not hold true of the stronger reading according to which there are *propositions* that are necessary as well as *a posteriori* (see Soames, 2011, p. 79).[9] Stock examples of necessities *a posteriori* are true identity statements with rigid designators flanking the identity sign such as, for example, 'Cicero = Tully,' or 'Water = H_2O.'

Although it arguably figures in Kripke, the third doctrine is more closely associated with David Kaplan. According to this doctrine, many singular terms are 'directly referential' (Kaplan, 1977, p. 493) – they contribute their referent, rather than some descriptive content, to the contents expressed by sentences comprising them. Standard examples of directly referential expressions are the rigid designators listed above: proper names, natural kind terms, and indexicals. Suppose that 'Venus' is directly referential. Then all it contributes to the content expressed by 'Venus is a planet' is the celestial body it refers to. Any directly referential expression designates rigidly. The converse does not hold. The description 'the actual inventor of the zip' picks out one and the same individual in all possible worlds, *viz.* whoever invented the zip in our actual world. But it arguably contributes the descriptive property *having actually invented the zip* to contents expressed by the statements it occurs in. Orthodox Kripkeans are thus prone to contrast proper names and natural kind terms with expressions comprising rigidifying devices such as 'actually,' or Kaplan's (1989, pp. 579–582) 'dthat.'[10] All these terms designate rigidly. But only the former qualify as directly referential.

The fourth doctrine translates the idea of direct reference into a view of propositions. According to this doctrine, singular statements comprising directly referential expressions express singular propositions. A singular proposition is composed of objects and properties,

and it can be symbolized by an *n*-tuple of these. Given that 'Venus' is directly referential, 'Venus is a planet' expresses the singular proposition < Venus, *being a planet* >. And given that 'here' refers directly, an utterance of 'Here it is nice' expresses < *o*, *being nice* > with *o* being the referent of 'here' in the context of utterance.[11]

Orthodox Kripkeanism adds a characteristic meta-semantics to these four semantic doctrines, yielding a distinctive picture of reference and communication. According to this meta-semantics, reference-fixing for proper names and natural kind terms is extra-semantic. What 'Cicero' or 'water,' respectively, refer to is not even partly determined by a sense-like semantic property these terms have. Their reference is entirely fixed by mechanisms feeding on non-semantic properties of the terms. Suppose our linguistic ancestors introduced 'Cicero' as a designator for the Roman orator who denounced Catiline, and 'water' as a designator for the watery substance of our acquaintance (to employ a convenient abbreviation). Orthodox Kripkeans insist that the descriptive properties *being the Roman orator who denounced Catiline* and *being the watery substance of our acquaintance* function as mere ephemeral auxiliaries; the same holds true for any other associated descriptive property. *How* anyone picked out the referents is incidental. All that is of semantic importance is *which* objects are assigned as referents.

A famous instance of this general idea is the 'causal-historic' account of reference as proposed by Kripke (1980) and Putnam (1975). On this view, the referent of a proper name such as 'Cicero,' as used in a community, is the very object assigned as referent at the historical origin of this use of the term (see Kripke, 1980, p. 96 f.; Putnam, 1975). Analogously, a natural kind predicate such as 'water,' as used in a community, applies to the items or samples that are of the same natural kind as the items or samples employed as paradigms at the historical origin of this use of the term. On the causal-historic account, then, the referent of a name or kind term α thus is "determined by a 'causal' chain of communication rather than a description" (Kripke, 1980, p. 59, fn. 22). It is thus fixed quite independently of any semantic property α already has.

Kripkeanism marks a radical break with the Fregean tradition in semantics. Fregeans insist that any expression α has as its fundamental semantic property a descriptive content or 'sense' (*Sinn*) capturing α's cognitive significance by spelling out how the term's referent is presented, identified, or thought of. Paradigmatically, the sense of a name such as 'Cicero' is a descriptive content that can be expressed by a definite description such as, let us assume, 'the Roman orator who denounced Catiline.' The sense of an expression plays a complex role. Sense (i) determines reference, (ii) captures cognitive significance, (iii) is grasped by competent speakers, and (iv) is part of what is believed, said, and communicated. The referent of 'Cicero' (if there is one) is the unique individual satisfying the associated condition of *being the Roman orator who denounced Catiline*, and it is by this description that speakers employing the term identify or think of its referent. To understand a term thus is to knowingly associate the (or at least: a) conventionally assigned sense with it. By the same token, to understand a sentence amounts to grasping the descriptive content, called a 'thought' (*Gedanke*) by Frege, composed of the senses of the expressions that make up the sentence. It is thoughts that are expressed and communicated by the (assertoric) utterances we perform.

Orthodox Kripkeans agree that this picture may, *modulo* socio-linguistic phenomena like Putnam's (1975, p. 227) 'division of linguistic labor,' be correct for descriptive terms such as 'grandmother.' But they consider it fundamentally flawed as a general account of meaning. Kripke (1980) influentially argues that any sense-based account of reference-fixing and understanding (and, by consequence, communication) fails for proper names and natural

kind terms. Orthodox Kripkeans conclude that these terms *simply do not have senses*. Their reference is fixed extra-semantically rather than by satisfaction, they designate rigidly and refer directly, and sentences such as 'Water is transparent' express singular propositions rather than Fregean thoughts. By consequence, competence with such terms cannot consist in grasping their senses, and what we semantically assert and communicate with (assertoric) utterances of sentences comprising them cannot be Fregean thoughts. These terms do not have senses, and these sentences do not express Fregean thoughts.

Advocates of 2D semantics as a rule accept Kripke's ideas concerning rigid designation and necessities *a posteriori*. This semantic consensus comes with a deep rift on meta-semantics. 2D Kripkeans like Kaplan and Stalnaker embrace the Kripkean meta-semantics and the picture of reference and communication that comes with it. 2D Fregeans like Jackson and Chalmers reject the Kripkean meta-semantics in favor of an account that explains semantic properties in terms of underlying descriptive meanings playing the roles of Fregean senses. In the context of 2D theories, this rift translates into different views on what the dependence of truth on meaning-fixing conditions comes to, and what the A-dimension is good for.

4 Kaplan's 2D Semantics for Indexicals

David Kaplan's (1977; 1989) semantics aims to cover pure indexicals such as 'today' (on which I will focus) alongside impure indexicals such as 'you' and demonstratives such as 'this.' Kaplan starts off with two 'obvious principles' (Kaplan, 1977, p. 492):

(i) The referent of an indexical systematically depends on the respective context.
(ii) Indexicals are directly referential.

The first principle looks innocuous enough. Who doubts that the referent of, say, 'today' varies with the day in question? Kaplan takes the second principle to be just as incontrovertible. He stresses that we evaluate utterances such as Pavarotti's 'I am famous' as saying *of* some individual that he is famous. All an indexical as used in a context does is to pick out some individual (person, date, time, place, etc.), and it is the individual picked out, rather than some way to identify it, that affects what is said and thus enters into the proposition expressed. However, Kaplan embraces a third idea that does not sit too easily with his principles:

(iii) 'Indexicals, in general, have a rather easily statable descriptive meaning.' (Kaplan, 1977, p. 498)

For example, we understand 'today' to mean something like 'the present day.' Kaplan even agrees that these descriptive meanings mediate reference and are known to competent speakers. They thus perform key functions of Fregean senses. But how can indexicals have sense-like meanings *and* be directly referential? Kaplan's 2D semantics for indexicals convincingly squares these two features of indexical expressions.

Kaplan's semantics pivots on two distinctions. First of all, he distinguishes "possible occasions of use – which I call *contexts* – from possible circumstances of *evaluation* of what was said on a given occasion of use" (Kaplan, 1977, p. 494). This is a distinction between

two kinds of possible situations. The former figure as those situations in which an utterance can be made. The latter figure as those situations at which what is said by a sentence in a context can be evaluated. Second, Kaplan distinguishes *contents* from *characters*.[12] This is a distinction between semantic properties. Contents are semantic properties of occurrences, whereas characters are semantic properties of types. The content of a sentence in a context *c* is what is said with that sentence in *c*. Likewise, the content of a sub-sentential expression in a context *c* is what it contributes to what is said in *c*. For indexical sentences, the content expressed will depend on features of the context the sentence occurs in. A character is a conventionally assigned linguistic rule that descriptively specifies, for any context *c*, which content an occurrence of the respective type expresses in *c*. We may think of the character of 'I' as the rule "I,' as used in any context *c*, refers to the speaker or writer in *c*' (see Kaplan, 1977, p. 505). And we may think of the character of 'today' as the rule "today,' as used in a context *c*, refers to the day of the context *c*.'

Kaplan's account neatly fits the 2D apparatus sketched above. Think of circumstances of evaluation as C-worlds, and of contexts of use as A-worlds. Following Kaplan, we may model contents as functions from circumstances to extensions. This makes them C-intensions. And we may conceive of characters as functions from contexts to contents. This makes them 2D intensions. The Kaplanian picture we arrive at, then, is this. Any sentence-type δ has a compositionally determined character. The character of δ is a 2D intension that specifies what is said with an occurrence of δ, that is, which content δ expresses for any context *c* (= A-world). The contents thus expressed are C-intensions, that is, function from circumstances of evaluations (= C-worlds) to truth-values. When δ comprises a directly referential term, this term receives a constant object of evaluation at any circumstance of evaluation. Which object this is is already fully settled by the context, and thus "simply independent of the circumstance" (Kaplan, 1977, p. 497). This is why Kaplan equates the contents expressed by utterances of such sentences more narrowly with singular propositions.

For illustration, consider the sentence 'I am famous.' Its character (=2D intension) specifies for any context of use *c* what is said with an occurrence of 'I am famous' in *c*. Given that 'I' is directly referential, as Kaplan maintains, any occurrence of 'I am famous' says *of* the speaker or writer in *c* that (s)he is famous. It thus expresses a content (= C-intension) that is true at some circumstance of evaluation (= C-world) just in case this person is famous in that C-world. Consider a context c_1 where Pavarotti utters 'I am famous.' The character of the sentence-type together with the fact that Pavarotti is the speaker in c_1 determines the content expressed, and this content is true at a circumstance of evaluation just in case Pavarotti is famous at that C-world. Since the context fully settles that Pavarotti is the unvarying object of evaluation, Kaplan thinks of the content expressed more narrowly as the singular proposition <Pavarotti, *being famous*> containing Pavarotti himself as a constituent.

Kaplan's account combines explanatory power with theoretical clarity. First, Kaplan's semantics neatly explains how indexicals can have sense-like descriptive meanings *and* be directly referential: indexical *types* have sense-like meanings in the form of characters, whilst their *occurrences* in contexts are directly referential. The character of an indexical α fixes what is said with an occurrence of α in a context. But it does not enter into the content thus expressed. Second, Kaplan's theory elegantly accounts for modal puzzles such as the contingency of the apparently necessary 'I am now here.' An utterance of 'I am here' by me now expresses a singular proposition comprising me, *this* time, and *this* place. This proposition

clearly is contingent – there are C-worlds where it is false. But the character of 'I am here' apparently guarantees that any utterance of it is true in the context in which it is uttered. Third, Kaplan's semantics explains how indexical utterances function in communication. I know that Pavarotti made a *de re* claim about Pavarotti by uttering 'I am famous,' since I know the character of 'I' and since I know of Pavarotti that he just spoke. I know the former by being a competent speaker, and the latter by being a perceptive observer. Fourth, Kaplan has a clear answer to what the dependence of truth on meaning-fixing conditions comes to, and what A-worlds are good for. The former comes down to ordinary context-dependence, and we need A-worlds to model contexts of use. (Kaplan has little use for A-intensions; his picture absorbs these into characters.)

Subscribing to the orthodox Kripkean account of proper names and natural kind terms, Kaplan intends his 2D theory to add to the orthodox Kripkean case. But Kaplan's work arguably transforms the Kripkean picture. To begin with, since characters are composite and since any non-indexical expression can be combined in sentences with an indexical, all expressions get assigned characters. The difference between 'I' and 'Pavarotti' is not that the former has, whereas the latter lacks a character. The difference is rather that the content expressed by 'I' varies with the context, whereas that of 'Pavarotti' does not. What is more, Kaplan adds descriptivist elements to a Kripkean theory. On Kaplan's semantics, indexicals designate rigidly, yield necessities *a posteriori* (consider 'Today = September 21, 2015,' as uttered on September 21, 2015), and refer directly. But their reference in a context is fixed by a character – and characters are sense-like descriptive meanings conventionally associated with these expressions.

This yields a worry. Why should we think of Kaplan's semantics as a Kripkean account, rather than as a sophisticated Fregean theory? To defuse this challenge, Kaplan insists that in his theory, content rather than character is the rightful heir to Fregean sense (see Kaplan, 1989, p. 568). He explains: "[T]he issue is not whether the information used to determine the referent is descriptive or not. It is rather whether the relevant information, in whatever form, *is a part of what is said*" (1989, p. 578; my italics). What Pavarotti expresses with an utterance of 'I am famous' is just the singular proposition < Pavarotti, *being famous*>. No thought-like descriptive meaning gets expressed. Kaplan here subscribes to an idea I call the *preeminence of C-intensions*: Contents (= C-intensions) are the exclusive semantic vehicles of linguistic communication. What gets semantically expressed, asserted, or communicated are C-intensions. Descriptive meanings play a role in communication only in so far as they happen to be C-intensions, as is the case with purely descriptive sentences. The preeminence of C-intensions is a deeply orthodox Kripkean idea. It is inspired by the Kripkean conviction that proper names, natural kind terms, and other directly referential expressions do not have descriptive meanings to contribute to what is said.

The preeminence of C-intensions arguably is an independently motivated commitment Kaplan adds to, rather than extracts from, his semantics. This feels problematic. On Kaplan's 2D semantics, every term has a character. But A-intensions are easily recoverable from characters. By consequence, in so far as competent speakers know the characters of their expressions, they should know the A-intensions their sentences semantically express. So, going by Kaplan's own semantics, why shouldn't we expect utterances of sentences to standardly express and communicate A-intensions over and above C-intensions? Even more worrisome to an orthodox Kripkean, we may well take Kaplan's treatment of indexicals as a blueprint to explain how names and natural kind terms can have full-blown Fregean senses even though they refer directly. This would allow us to acknowledge Kripke's semantic

doctrines, yet reject the Kripkean picture of reference-fixing. Such a 'generalized Kaplan paradigm' (Stalnaker, 2004, p. 309) would be a Fregean rival to orthodox Kripkeanism.

5 Robert Stalnaker, or 2D Pragmatics

Robert Stalnaker also commits to the orthodox Kripkeanism picture according to which C-intensions are the exclusive semantic vehicles of linguistic communication. He prominently acknowledges, however, that this picture faces challenging puzzles (see Stalnaker, 1978; 2004; 2014). Most pressingly, its champions need to explain how sentences expressing non-informative C-intensions can be informatively asserted, as they manifestly are. Stalnaker relies on the 2D apparatus to propose a pragmatic solution to these puzzles (see Stalnaker, 1999, pp. 12–19, for an overview).

Here is a claim about information: To be informative (to carry information, to represent) is to 'exclude possibilities' (Stalnaker, 2004, p. 300; see Jackson, 2001, p. 617). A statement is informative in a context *c* only if the proposition it expresses in *c* excludes some of the possibilities compatible with *c*. Should I choose to accept it, such a statement allows me to narrow the range of possible worlds that I, by the standards of the context, consider as candidates for the situation I actually am in. By the same token, to assert that *p* is to propose "to exclude from the possible situations compatible with the context those in which the proposition asserted is false" (Stalnaker, 2004, p. 300). Suppose you assert 'Today is Monday.' You here propose to exclude all the non-Monday-worlds from our common representation of how our present situation might be.

Although quite compelling, our little theory entails that informativity requires contingency. A statement *p* is informative only if there is at least one non-*p*-world. This leads to a puzzle. We clearly make informative assertions using statements such as 'Hesperus = Phosphorus,' or 'Water = H_2O.' But on orthodox Kripkean premises, statements such as these exclusively express necessary (singular) propositions that do not exclude any possibility. For example, 'Hesperus = Phosphorus' exclusively expresses < Venus, *being identical with*, Venus>. So we need to explain "how it is that a necessarily true statement could be used to convey contingent information?" (Stalnaker, 2004, p. 303).

Stalnaker's pragmatic resolution of this puzzle is premised on a causal theory of reference. To this, he adds two ideas. First, the meanings of proper names, natural kind terms, and the like are contingent in a specific manner. Consider a possible world *w* where the watery substance of our acquaintance is XYZ, rather than H_2O. Suppose we had introduced 'water' just as we actually did relying on the property *being the watery substance of our acquaintance*, but that *w* happened to be the actual world. Then our term 'water' had rigidly designated XYZ, rather than H_2O. The meanings of all the other terms governed by a causal-historic semantics do likewise depend on the respective actual world. We can employ the 2D apparatus to model this dependency. Let us understand A-worlds to be alternative *actual* worlds, that is, possible candidates for the world we actually inhabit. (If you like, A-worlds are counter*actual*, whereas C-worlds are counter*factual*.) Then the A-intension f: $W_A \rightarrow E$ of a term α specifies, for any A-world *w*, which extension α would have, given that *w* was actual. Thus understood, any A-intension is metalinguistic. It specifies what α would mean, rather than what it actually does mean.

Second, when an utterance violates a pragmatic maxim, we reinterpret. Suppose some utterance of 'It is raining' violates the Gricean maxim of relevance. We then look for the

alternative relevant content the speaker intends to convey with his utterance. What she might want to convey is that no, she does not want to go to the zoo. Stalnaker maintains that we do precisely the same when confronted with an assertion of a sentence expressing a non-informative necessary proposition such as 'Hesperus is Phosphorus.' (This of course presupposes that competent speakers recognize that 'Hesperus is Phosphorus' expresses a necessary and thereby non-informative proposition in the first place, and so see a need to re-intepret.) Here we look for an alternative informative proposition the speaker intends to convey. We do not have to look far. As explained above, the likes of 'Hesperus' have their C-intensions contingently. By consequence, the A-intension of a sentence such as 'Hesperus = Phosphorus' or 'Water is H_2O' will as a rule be contingent, too. So what we do by default is to *diagonalize*: we understand the speaker as intending to convey the contingent and therefore informative propositional A-intension or 'diagonal proposition' (Stalnaker, 1978, p. 318) the sentence has in the present context, rather than the necessary C-intension the sentence semantically expresses given the present context.

Stalnaker takes this "diagonalization strategy" (Stalnaker, 2008, p. 42) to provide a general solution to our puzzle. He also understands diagonalization to be a purely pragmatic maneuver. The A-intensions we enlist in diagonalization are not additional semantic values. They rather capture metalinguistic facts about the variability of meaning on a par with platitudes such as, say, 'Had we named Venus 'Mars,' 'Mars' would designate Venus.' So, although Stalnaker proffers a 2D account, he does not propose a 2D *semantics*. Stalnaker rather vigorously sticks to orthodox Kripkeanism, and he employs 2D techniques precisely in order to avoid committing to a two-dimensional semantics.

The success of this maneuver can be questioned, however. Stalnaker introduces diagonalization as a general strategy. But for any normal context *c* in which some directly referential term may plausibly occur, this term may plausibly figure in *c* in a sentence expressing a necessary C-intension. Suppose you are talking about water. Then uttering 'By the way, water is H_2O, as I have recently learned' is fairly unremarkable. So diagonalization must basically cover all directly referential terms and all the normal contexts these can occur in. But to diagonalize within some context *c* requires that speaker and hearer share in *c* descriptive knowledge rich enough to uniquely identify the actual referent of the directly referential expression concerned. When confronted with the uninformative 'Water is H_2O,' for example, you need to enlist some descriptive property that the actual referent of 'water' uniquely satisfies, at least in the context. So if Stalnaker is right about diagonalization, he seems compelled to grant that competent speakers knowingly associate descriptive contents that uniquely identify referents with their directly referential terms (basically) across the board. Any Fregean will take this to be a major concession.

Stalnaker does not think so. He emphasizes that the descriptive knowledge associated with a directly referential term varies with the context, and he insists that it is pragmatic rather than semantic. But the actual extent of the variation is debatable, and any Fregean theory of reference, especially one built around a cluster-theory such as, for example, Searle's (1958) account of names, has us expect a good deal of contextual variation in what is saliently communicated anyhow. Yet if that is so, what justification is there to class the associated descriptive content as pragmatic rather than semantic?

In fact, Stalnaker's concession creates a more serious problem. It threatens to undercut the very Kripkean model of communication diagonalization was designed to salvage. Stalnaker assumes that standard communication exclusively involves C-intensions. Diagonal propositions (= A-intensions) are communicated only when normal communication

breaks down, or so Stalnaker maintains. But as we have seen, competent speakers are bound to knowingly associate A-intensions with their directly referential terms across the board, even though these might vary with the context. They also are bound to knowingly associate A-intensions with their descriptive terms across the board, since here A- and C-intensions coincide. But if speakers are aware of the contextually indicated A-intensions of their terms anyway, shouldn't we expect that utterances of sentences comprising directly referential terms standardly communicate contextually indicated A-intensions as well?

6 Enter the 2D Fregeans: Jackson, Chalmers, and the Primacy of A-Intensions

Jackson and Chalmers agree that the Kripkean meta-semantics is misguided and that those who assign C-intensions preeminence in reference and communication have things backwards. However, they accept Kripke's doctrines of rigid designation and necessities *a posteriori*. (They could acknowledge direct reference and singular propositions, too, but may well see no need to do so.) So Jackson and Chalmers devise a 2D Fregean semantics that accounts for these semantic doctrines. Jackson and Chalmers welcome the support their semantics lends to conceptual analysis. Their 2D Fregeanism explains what conceptual analysis aims at (it aims at ascertaining A-intensions), and it explains why conceptual analysis is feasible even for natural kind terms such as, for example, 'causation' (it is so feasible because even natural kind terms have A-intensions) (see Jackson, 1998, ch. 2). However, Jackson and Chalmers harbor different ideas about the status and aim of the 2D Fregean projects they pursue. They consequently take rather different views on why we should hold that A-intensions are fundamental, and in what sense knowledge of A-intensions is *a priori*.

The semantics Jackson and Chalmers devise is Fregean in that it assigns all our expressions or their occurrences a sense-like descriptive content that (i′) plays a key role in determining reference, (ii′) captures a kind of cognitive significance, (iii′) is grasped by competent speakers, and (iv′) is often part of what is said and communicated. The semantics Jackson and Chalmers devise is two-dimensional in that it assigns any expression or occurrence an A-intension and a C-intension (with the latter potentially varying with the actual world as described by a 2D intension). These are not on a par. Rather, A-intensions are fundamental in that they fit the profile laid out by (i′)–(iv′) and thus basically play the role of Fregean senses. More specifically, a 2D Fregean semantics assigns any expression an A-intension, that is, a function f: $W_A \rightarrow E$ from actual worlds to extensions, and a C-intension, that is, a function f: $W_C \rightarrow E$ from counterfactual worlds to extensions. The C-dimension is interpreted traditionally. C-worlds are understood to be worlds considered as counterfactual and equated with comprehensive metaphysical possibilities, and C-intensions are taken to be the familiar traditional intensions. The A-dimension, however, is now seen as genuine semantic, as well as fundamental. A-worlds are understood to be worlds 'considered as actual,' that is, alternative actual worlds, and A-intensions are understood to be descriptive contents. A-intensions here do not metalinguistically trace changes *in* meaning, as they do in Stalnaker's account. They rather capture the descriptive contents our terms have as we actually use them.

On the 2D Fregean picture, then, any term or occurrence has a descriptive content as given by its A-intension. These contents are fundamental in that they determine C-intensions. Here we need to distinguish two cases. Either the A-intension of a term α all by itself

determines α's C-intension. This holds true for terms like 'grandmother' whose C-intension does not vary with the actual world. The A- and C-intensions of these terms coincide (given that we ignore centering). Or the A-intension of a term α fixes α's C-intension together with the actual world. This holds true for terms like 'water' or 'the actual inventor of the zip' whose C-intensions do depend on the actual world, or, more specifically: on what the actual watery substance of our acquaintance happens to be, and on who actually invented the zip, respectively.

Applying this account to descriptive terms such as, for example, 'triangle' or 'grandmother' is straightforward. A descriptive property determining what 'grandmother' applies to is easy to find: 'grandmother' applies to female parents of parents. The term's A-intension thus is a function from A-worlds to sets of female parents of parents. This A-intension by itself determines the term's C-intension. Since 'grandmother' applies to female parents of parents regardless of how the actual world happens to be, both its A- and its C-intension mark the very same function from worlds to female parents of parents (again, given that we ignore centering).

In applying their ideas to names and natural kind terms, the 2D Fregeans in effect take their cue from Kaplan. Kaplan equates the character of an indexical α with a rule descriptively identifying the referent of α for any context, and α's content with whatever satisfies that rule in the respective context *c*. The former remains stable across contexts, whereas the latter may vary. Substituting actual worlds for contexts of use and taking the distinction between A- and C-intensions to concern types and tokens alike, the 2D Fregean applies her ideas to proper names or natural kind terms in much the same fashion. She equates the A-intension of some such term α with the role carved out by the descriptive property associated with α, and she equates the C-intension of α, given that some A-world *w* is actual, with whatever fills that role in *w*. The former remains stable across A-worlds, whereas the latter may vary. Suppose we equate the A-intension of the natural kind term 'water' with the role of *being the watery substance of our acquaintance*. Then this is what 'water' stably refers to across A-worlds. Given that some A-world *w* is actual, the term's C-intension then is whatever happens to fill that role in *w*. 2D Fregeans thus hold that names and natural kind terms are *actuality-dependent* by virtue of their meaning – it is built into the semantics of 'water' that the term rigidly designates H_2O *if* the actual world is one where H_2O is the watery substance of our acquaintance, and that the term rigidly designates XYZ *if* the actual world is one where XYZ is the watery substance of our acquaintance, and so on. The analogous holds true for sentences. Here the conditionals connect actual worlds to truth-values.

The 2D Fregean semantics yields a general idea about competence: to be competent with a term or token α is to know its A-intension. To know this is of course to know the role carved out by the descriptive property associated with α, and we can depict what is so known by a set of conditionals of the form 'If w_1 is actual, α applies to the Xs,' 'If w_2 is actual, α applies to the Ys,' and so on. The idea is not that those competent with α share descriptive knowledge associated with α ready to be put into words. The idea is rather that the knowledge is implicit and that competent speakers share an ability: "If a subject possesses a concept and has unimpaired rational processes, then sufficient empirical information about the actual world puts a subject in a position to identify the concept's extension" (Chalmers and Jackson, 2001, p. 323). Here looms a threat of triviality. The exercise becomes pointless if the information given already presents the actual world in terms of the concept whose extension we try to determine – if you describe the world in terms of grandmothers, figuring out the extension of 'grandmother' hardly poses a challenge

to me. So we need to assume that the information is somehow provided in a neutral fashion (as Chalmers does, see below, §8). Granted that it is, the claim appears plausible for descriptive terms. Tell me who the females and the parents are in some A-world *w*, and I can pick out the grandmothers in *w*, although I still might be hard pressed to put the descriptive property guiding my application into words. According to 2D Fregeans, the same holds good for names and natural kind terms. Consider 'water.' Here it is claimed that "sufficient information about the distribution, behavior, and appearance of clusters of H_2O molecules enables the subject to know that water is H_2O, to know where water is and is not, and so on" (Chalmers and Jackson, 2001, p. 323). This again is a question of being able to apply the term 'water.' It is not a question of being able to put the descriptive property guiding this application into words.

The 2D Fregean semantics also affords a deflationist account of necessities *a posteriori* (see Davies and Humberstone, 1980, p. 18, who also analyze identity statements involving natural kind terms along these lines). Knowledge of A-intensions is assumed to be *a priori*. By knowing the A-intension of 'water,' we know *a priori* that 'water' applies in any A-world *w* to whatever is the watery substance of our acquaintance in *w*. But there are A-worlds where H_2O plays this role, and there are A-worlds where something else does, and no amount of *a priori* reasoning will tell us that the world we happen to live in is of the former variety. This we need to determine empirically. So the A-intension of the *a posteriori* 'Water is H_2O' will come out false at some A-world and is thus contingent. In effect, being *a posteriori* and having a contingent A-intension are two sides of the same coin. Now, 'water' is actuality-dependent in that the term rigidly designates whatever actually fills the role carved out by its A-intension. But the world we happen to live in is one where H_2O plays the role of being the watery substance of our acquaintance. Hence, the C-intension the term 'water' has in our mouths here picks out H_2O in all C-worlds. So the statement 'Water is H_2O' as we actually employ it expresses a necessary C-intension. All other necessities *a posteriori* are accounted for in the same fashion. Any such statement is *a posteriori* in that it has a contingent A-intension, and it is metaphysically necessary in that it has a necessary C-intension. This idea is deflationist in that it makes do without acknowledging propositions that are necessary as well as *a posteriori*.

7 Jackson, or Why Communication Requires a 2D Semantics

Jackson employs his 2D Fregean account to defend general ideas about linguistic meaning. Since his account requires known associations of words with properties (see below), it is not fit to serve also as a theory of mental representation (see Jackson, 2004, p. 275). Jackson's view is rooted in what he deems a folk-theoretic insight into language: Language is a system of representation designed to facilitate the conveying of information. Its key "job is to represent, in a way accessible to actual and potential hearers and readers, how things are according to the speaker or writer" (Jackson, 2005, p. 257). Our words are up to this task because competent speakers resiliently and knowingly associate properties with their words. For example, we associate a specific shape property with 'circle,' and a distinct dispositional property with 'fragile.' These associations need to be resilient in order to allow speakers to rely on them when they employ language to convey putative information. These associations must moreover be known in order for the conveying of putative information to be effective – if you do not know what 'fragile' means, the point of printing that word on a

parcel will be lost on you. Given that the association between a property *F* and a word α in a community is resilient as well as known, *F* is what α as employed in that community semantically contributes to how sentences containing α represent things as being.

The picture sketched assigns sense-like descriptive contents as characterized by (i′)–(iv′) above a key role in semantics. Jackson identifies these descriptive contents with A-intensions in the sense of functions f: $W_A \rightarrow E$ from actual worlds to extensions. This allows him to embrace the general 2D Fregean explanations sketched above. It also puts him in a position to say how A-intensions are fixed: they are put in effect by our conventions linking words to properties, be they direct (as in the association of, say, 'circle' with the respective shape property) or, as will quite often be the case, mediated by our (folk-)theories (as in the association of, say, 'water' with the complex property our folk account of water delineates). On Jackson's view, then, A-intensions are fundamental because they are the basic semantic properties we conventionally assign to our words. Our knowledge of A-intensions moreover comes out *a priori* in a very specific sense. To understand the language I speak is to know which descriptive properties are by convention associated with my words. This suffices to know the A-intensions of my expressions. I do not need to know any further fact. I especially do not need to know what the world that happens to be the actual one is like non-conventionally, and "[w]hat we can know independently of knowing what the actual world is like can properly be called *a priori*" (Jackson, 1998, p. 51). It thus is *a priori* to competent speakers that grandmothers are female for the simple fact that we by convention associate 'grandmother' with the property of *being a female parent of a parent* in a way that does not make this association contingent on any (non-conventional) aspect of the actual world. By contrast, the fact that 'water' designates H_2O is contingent on such an aspect, *viz*. that in the actual world, it is H_2O that plays the role carved out by the descriptive property our conventions assign to 'water.'

Jackson accounts for the rigidity of proper names and natural kind terms by their actuality-dependence (see Jackson, 2004, pp. 261 f.). He also stresses that his view allows competent speakers to have mere implicit knowledge of the associations of words and properties, that the properties concerned might well be causal and egocentric (which is easy to grant given that A-worlds are centered), and that associated properties may vary with the sociolect, rather than the language spoken. Jackson adds a causal-descriptivist account for these terms (see Jackson, 2010; 2005; 2007). The pivotal idea here is that Kripke is right to hold that the reference of proper names is fixed causal-historically, but that competent speakers *know* this. More precisely, a competent speaker knows for any particular name-token α she comes across that its referent "stands at the far end of the information-preserving causal chain […] whose near end is the person making the claim and the token they produce" (Jackson, 2010, p. 141; cf. Jackson, 2007, pp. 20–22). This account explains how we can informationally exploit even names we have never encountered before. It also explains why there is general agreement about what 'Gödel' refers to in Kripke's 'Gödel'-case, which is hard to account for on a pure causal-historic theory (see Jackson, 2007; 2004, p. 273). Still, Jackson's causal-descriptivism explains this at the cost of bestowing rather thin and worryingly schematic senses on proper names in general.

The general positive argument Jackson relies on appears more promising (see Jackson, 2004, pp. 266 ff.; 2005; 1998, p. 40, fn. 16). No one doubts that "[w]ords like 'water,' 'gold,' 'elm,' 'quark,' and so on, are very useful for saying how things are, co-ordinating behavior, transmitting information, and so on" (Jackson, 2004, p. 270). In fact, we can employ these terms to convey putative information to just about any competent hearer (or reader) within our linguistic community, just as we can do with 'fragile' or 'dangerous.' However, for this to

work, Jackson argues that the hearers (or readers) need to knowingly associate properties with the former expressions as well, otherwise we could not account for our success in transmitting information suited to coordinate behavior. Jackson concludes that we in fact knowingly associate properties even with our natural kind terms and proper names. This is precisely the core contention of his 2D Fregeanism.

Jackson tends to present this line of thought as a folk-theoretic insight not yet tainted by philosophical theorizing. This will hardly sway the orthodox Kripkean who anyway subscribes to a revisionist program. She won't find it hard to discard Jackson's truism as a commonsensical semantic prejudice to be revised in the light of Kripke's theory. However, Jackson's line of thought can also be construed as a direct argument aiming to show that we cannot account for our reliable success in linguistic communication suited to coordinate behavior without assuming resiliently associated properties (see Nimtz, 2010, §7). The orthodox Kripkean has a ready reply to this challenge, though. She can argue that her semantics can account for linguistic communication suited to coordinate behavior – provided that we combine it with a Stalnakerian 2D pragmatics.

8 Chalmers's Epistemic Two-Dimensionalism

Judged from the perspective of the philosophy of language, Chalmers's 2D Fregeanism appears more modest than Jackson's. Chalmers's 2D semantics merely aims at tokens rather than types, and he is content to elucidate "utterance content" (Chalmers, 2010, p. 557) rather than shared linguistic meaning. However, Chalmers does not primarily conceive of his project as a contribution to the philosophy of language. His 2D Fregeanism aspires rather to be a general rationalist account of representation and modality establishing A-intensions as a viable kind of content. There are two aspects to this. First, Chalmers's 2D semantics applies to language and mind. He thinks of A-intensions as providing an explanatorily fruitful variety of content both for linguistic tokens and for occurrences of mental states. Second, Chalmers thinks of A-intensions as constitutively tied to modality and to reason (see Chalmers, 2004, pp. 153 f.; Chalmers 2006, pp. 55 f.). A-intensions are constitutively tied to modality in that they concern what is possible and necessary. A-intensions are constitutively tied to reason in that they are defined in terms of what an ideal reasoner can know *a priori* (as we shall presently see). Learning about A-intensions and their conceptual interrelations thus promises to be an *a priori* means to learn about what is possible and necessary. Chalmers welcomes this rationalist upshot. He thinks that *a priori* reflection is indeed a way to learn, *via* insight into A-intensions, about the nature of the mind (see Chalmers, 2010) or the fundamental structure of reality (see Chalmers, 2012). However, Chalmers does not premise his 2D Fregeanism on rationalist ideas. He rather develops a 2D semantics that, if true, would vindicate his rationalism. He goes on to defend this account, reaping a vindication of his rationalism as a consequence.

Chalmers's exposition of his view is comprehensive, complex, and detailed. This is in part owed to Chalmers's pluralism. Chalmers readily acknowledges semantic values other than A-intensions and allows alternative understandings of key concepts. To keep things manageable, I chart just one course through the space of options Chalmers provides.

The key to Chalmers's 2D Fregeanism is an epistemic reading of the A-dimension. We should, he urges, understand A-worlds and A-intensions in terms of ideal *epistemic* possibility. Epistemic possibility specifies what is compatible with what someone does or

can know, rather than what could be the case *simpliciter*. A claim *p* is an epistemic possibility if *p* could be the case *for all we know*. It is an *ideal* (or in Chalmers's terms: *deep*) epistemic possibility if *p* could be the case *for all an ideal reasoner can know a priori*. The simplest epistemic reading straightforwardly identifies A-worlds with maximally specific ideal epistemic possibilities or *scenarios*, as Chalmers calls them. (See Chalmers, 2010, appendix. See Chalmers, 2004, for alternatives.) A-worlds then stand to comprehensive epistemic possibilities just as C-worlds stand to comprehensive metaphysical possibilities. These possibilities differ. Given that 'Hesperus = Phosphorus' is metaphysically necessary, there is no C-world where 'Hesperus = Phosphorus' comes out false. However, there are no *a priori* grounds to rule out that Hesperus ≠ Phosphorus. So there will be an epistemic A-world or scenario where 'Hesperus' denotes something other than 'Phosphorus.'

Chalmers assumes that any scenario is given by a *canonical description* that comprehensively characterizes the scenario in neutral qualitative terms. He relies on canonical descriptions to avoid the triviality of presentation problem mentioned above and to explain what epistemic A-intensions come to. Chalmers identifies A-intensions with functions f: $W_A \rightarrow E$ from epistemic A-worlds to extensions. But what is it for a sentence – say, the sentence 'Venus is bright' – to be true at some epistemically possible A-world? The analogous question for C-worlds is easy to answer. The sentence is true at some C-world *w* just in case *w metaphysically necessitates* it. This holds true just in case the counterfactual conditional '$D_W \,\Box\!\!\rightarrow$ Venus is bright' is true, where D_W is a canonical description of *w*. The same idea applies to A-worlds. Our sentence is true at some epistemic A-world *w* just in case *w epistemically necessitates* it. This holds true just in case the indicative conditional '$D_W \rightarrow$ Venus is bright' is epistemically necessary, that is, *a priori* to an ideal reasoner. Epistemic A-intensions thus "represent the *epistemic dependence* of the extension of our expressions on the state of the world" (Chalmers, 2004, p. 176). So to know the A-intension of a sentence δ is to know *a priori* whether or not δ holds true given that some canonical description *D* truly describes our world.

It is built into Chalmers's epistemic 2D semantics that *apriority* and A-necessity coincide: a sentence token is *a priori* if and only if its A-intension holds true at all A-worlds. (Chalmers sometimes allows unknowable mathematical truths to be an exception to this.) This *core thesis* ties A-intensions to the rational domain. It guarantees that one can learn *a priori* what is A-possible and A-necessary. Now recall the key principle of 2D Fregeanism mentioned above: A-intensions determine C-intensions, either by themselves or together with the actual world. Taken together, these principles explain why, on Chalmers's epistemic account, learning about A-intensions is indeed an *a priori* means to learn about what is non-epistemically possible and necessary. Suppose I have *a priori* determined that 'There is no perfect being' is an epistemic possibility. I thus know that its A-intension holds true in at least one A-world. But the sentence does not contain any terms whose C-intension varies with the actual world. The C-intension of the whole sentence thus cannot differ from its A-intension. I can therefore conclude that the C-intension of 'There is no perfect being' holds true at one C-world, and thereby expresses a metaphysical possibility. Armchair *a priori* insight here directly translates into insight into what is metaphysically possible. When it comes to sentences whose C-intensions do vary with the actual world, things are more complicated. By itself, *a priori* insight into the A-necessity of 'Water = the watery substance of our acquaintance' does not provide insight into a metaphysical necessity. However, we merely need to add the empirical result that the actual watery substance of our acquaintance is H_2O to conclude that 'Water = H_2O' is metaphysically necessary.

Jackson thinks that A-intensions are *a priori* because our associations of terms and properties are purely conventional. Chalmers's rather more robust understanding of the *apriority* of A-intensions rests on his principle of the *scrutability of reference and truth*. Suppose I know a correct canonical description *D* of my world. If reference and truth are scrutable, as Chalmers claims they are, I am then in a position to know, without any further empirical information, what my terms refer to and which of my sentences are true. Chalmers derives this principle of scrutability from the idea that our expressions have a 'normative inferential role.' He explains thus: "[F]or any expression we use, […] given sufficient information about the actual world, certain judgments using the expression will be irrational, and certain other judgments using the expression will be rational" (Chalmers, 2010, p. 555). He goes on to stress that it is "this sort of inferential role that grounds the primary intension of an arbitrary expression (as used by an arbitrary speaker)" (p. 555).

Chalmers argues at length that our expressions do have normative inferential rules (at least for the individual speaker), and that scrutability holds true. His case for the former is positive: he discusses examples where he judges the claim to hold and generalizes from these (see Chalmers and Jackson, 2001). Chalmers's case for the latter is negative: he patiently discusses potential counter-examples to scrutability and finds them all wanting (see Chalmers, 2002b, pp. 174–195). Chalmers clearly believes that his 2D semantics will stand and fall with such overarching principles, and not with its success in explaining humdrum semantic phenomena. This is only partly due to the fact that Chalmers does not intend his 2D theory to be a semantics for a shared natural language. Given his pluralism, Chalmers can easily countenance alternative semantic accounts postulating semantic values other than epistemic A-intensions. Chalmers's semantics is only vulnerable to accounts that, like orthodox Kripkeanism, straightforwardly declare that some of our terms do *not* have epistemic A-intensions, even for the individual speaker.

9 An Upshot, or the State of the Debate

There is little general dispute about the two-dimensional approach within philosophy. Quite the opposite, two-dimensional theorizing is well-established in contemporary philosophy of language. This is in large part due to Kaplan's groundbreaking 2D semantics for indexicals and Stalnaker's somewhat less appreciated 2D pragmatics. There is little dispute about either account. In fact, going two-dimensional by embracing either is seen as a natural and *per se* non-contentious move for theorists working in the Kripkean tradition. In sharp contrast to this, both Jackson's 2D semantics and Chalmers's epistemic two-dimensionalism remain rather controversial, with no agreement on results (see, e.g., Schroeter, 2012; Elliott, McQueen, and Weber, 2013; Speaks, 2014). In part, this may well be owed to the complexity of the issue. To realize their revisionist agenda, 2D Fregeans need to do quite a lot. They need to devise a compelling Fregean semantics that respects Kripke's semantic insights and accommodates Kripke's anti-descriptivist arguments. They also need to convince us that a revision of orthodox Kripkeanism is called for in the first place. The success of any of these tasks is hard to gauge. So the success of any 2D Fregean semantics is likely to always be a matter of some debate. In part, this might well be due to the fact that participants in the debate harbor rather different ideas as to what a semantics should accomplish in the first place. One might well hope, then, that advances in meta-semantics will allow for a more nuanced assessment of 2D Fregean accounts.

Notes

1 I will talk throughout as if the functions and so on that a semantics assigns to expressions are meanings. This is not meant to beg the question against those who, like Kaplan (1977, p. 502), think that these set-theoretic entities merely represent or model meanings.

2 The entities employed in 2D semantics go by different names, and I will indicate who calls what by which name in due course. Still, I need to make a terminological choice, so I follow Jackson (1998; 2004) in my terminology. This is a choice of convenience, not a theoretical commitment.

3 I employ the terms 'semantic' and 'meta-semantic' in their usual meanings. A semantics for certain expressions specifies *which* semantic properties these expressions have. A meta-semantics for certain expressions explains *how* or *why* these expressions came to have those semantic properties in the first place. Kaplan (1989, pp. 573 f.) uses 'meta-semantic' differently. He dubs an account explaining why certain expressions have their semantic properties – a meta-semantics in the standard sense – 'meta-semantic' only if it exclusively enlists non-semantic properties to do the explaining.

4 2D Kripkeans and 2D Fregeans disagree on the fundamentals. However, they can well agree on many specific semantic or pragmatic issues, for example, how to treat indexicals, or how to solve pragmatic puzzles.

5 This makes Kripke's (1971, p. 153) claim that we know conditionals such as 'If this lectern is made of ice, it is necessarily made of ice' by "a priori *philosophical* analysis" (my emphasis) all the more puzzling.

6 $P(\mathrm{D})$ is the power-set of D, that is, the set of all subsets of D.

7 Stalnaker (2014, p. 225) holds that strictly speaking, diagonal propositions involve only uncentered worlds. I ignore this.

8 The following applies to 2D semantics. Things are different with a Stalnaker-style 2D pragmatics.

9 Such a reading would take the phenomenon to be metaphysical, rather than primarily semantical, and undercut the deflationist account of necessities *a posteriori* embraced by 2D Fregeans. See §6.

10 The expression 'dthat(the *F*)' rigidly designates whatever actually satisfies the embedded description 'the *F*.' For example, 'dthat(the second planet from the Sun)' rigidly designates the planet Venus. The claim made in the text holds true on the reading of 'dthat' as an operator only. With 'dthat' read as a term-forming device, the resulting expression is directly referential. See Kaplan (1989, pp. 579–582).

11 Kripke (1980, p. 21) expresses reservations about casting his ideas in terms of 'propositions.' But he has no qualms to talk of 'propositions' in his 1976 John Locke lectures where he evidently conceives of propositions as Russellian (see Kripke, 2013, lecture II). Some (see Soames, 2011, pp. 78 f.) think that a specific view of attitude ascriptions is part and parcel of the view of propositions a Kripkean commits to. I consider this to be controversial, and thus beyond the fourth doctrine as stated. This seems also right for dialectical reasons: Whatever 2D Fregeanism is, it is not *per se* an account of propositions and attitude ascription.

12 Kaplan uses 'content' as a technical term applying only to those contents (in the encompassing sense of the term) that play the role of what-is-said in contexts and are often singular propositions.

The Semantics and Pragmatics of Indexicals

JOHN PERRY

1 Introduction

The term 'indexical' comes into the philosophy of language from Charles Sanders Peirce's use of the term 'index.'[1] Here is an explanation of Peirce's threefold division of signs: icon, index, and symbol:

> Signs are icons, indices (also called "semes"), or symbols … accordingly as they derive their significance from resemblance to their objects, a real relation (for example, of causation) with their objects, or are connected only by convention to their objects, respectively. (Burch, 2014)

Suppose I am talking face-to-face with Elwood Fritchey. There is a completely arbitrary convention that allows me to refer to him as 'Elwood.' Although in this case he is standing before me – a "real" relation – that has nothing to do with the fact that I refer to him when I say "Elwood." I will be able to refer to him by using 'Elwood' after he has gone. The work of securing reference is done by the convention, and does not depend on any further connection between the speaker and Elwood. So 'Elwood,' it seems, is a symbol, connected to Mr Fritchey only by convention.[2]

One of Peirce's central examples of indexicals was smoke, which is a sign of fire. Here the real relation is causation: fire causes smoke. No convention is involved, and no language. Smoke is a natural sign of fire, not a conventional one.

But the term 'indexical' is not much used for natural signs in contemporary philosophy of language. It is used for words like 'I,' 'you,' 'here,' and 'now,' which clearly have conventional meanings. However, their conventional meanings do not determine the reference of uses of such expression all by themselves. I can use 'you' to refer to Elwood, given its conventional meaning, because Elwood is the person I am talking to. This is a real relation between Elwood and Me, involving causation and perception. This kind of conventional indexicality

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

is the phenomenon for which "indexicality" is used in contemporary philosophy of language, and will be our topic here.

Paradigm indexicals include pronouns such as 'I' and 'you,' as well as words like 'here,' 'now,' 'today,' 'tomorrow,' and 'yesterday' that occur as both nouns and adverbs. We'll look at how such paradigms work, then look at less paradigmatic examples, and eventually try to arrive at plausible definitions of *indexical* and *indexicality*.

When I say "I," I refer to myself. When you say "I," you refer to yourself. We use the same word, with the same meaning, but we refer to different persons. This is a characteristic of indexicals; the meaning of the expression does not wholly determine its *reference* on a given occasion of use, or as I shall say, the reference of a given *utterance* of the expression.[3] The meaning of an indexical determines its reference only in combination with the *context*, that is, in combination with facts about the particular utterance. In the case of 'I,' the relevant fact is who the speaker is. The meaning of the expression 'I' is captured by the rule: an utterance of 'I' refers to the speaker of that very utterance. Similarly, for our other paradigms:

An utterance *u* of 'you' refers to the person the speaker of *u* is addressing;
An utterance *u* of 'now' refers to the time of *u*;
An utterance *u* of 'today' refers to the day that includes the time of *u*;
An utterance *u* of 'tomorrow' refers to the day after the day that includes the time of *u*;
An utterance *u* of 'yesterday' refers to the day before the day that includes the time of *u*.

Generalizing from these examples, we get a simple theory of indexicals:

If α is an indexical, the *meaning* of α is a function from utterances to objects that is conventionally assigned to α. The referent of an utterance *u* of α is the value of that function with *u* as argument.

In the cases of 'I,' 'here,' and 'now' the relation arguably provides a *total* function; every utterance has a speaker, location, and time.[4] But in many cases we have only *partial* functions. I think I hear a knock at the door, and say "You can come in." But it was just an odd noise; there is no one at the door; I'm not addressing anyone; my utterance of 'you' doesn't refer to anyone. More subtly, I may start my utterance of 'today' just before midnight, and end it just after. There is no one day that includes the time of my utterance. Or, more dire, perhaps today is the end of days. Then my use of 'tomorrow' doesn't refer to anything. And working on this chapter is rather futile.

This simple theory will need to be modified. But it will suffice to make some initial points, distinctions, and contrasts with other approaches.

2 Approaches

It's not very difficult to see how paradigm indexicals work. The difficulties and controversies have more to do with how to fit accounts of indexicals into more general theories of meaning, cognitive significance, and pragmatics.

Eliminative theories treat indexicals as short-cuts for descriptions that the speaker has in mind. Indexicals play no essential role in language and communication and can be eliminated for serious purposes. Perhaps I think of myself as Stanford's oldest living non-Norwegian philosopher. Then perhaps we would translate my utterance "I moved to The

Bay Area in 1974" as "Stanford's oldest living non-Norwegian philosopher moved to The Bay Area in 1974."

This approach is not very plausible. I haven't always thought of myself in this way. But I seem to say the same thing with my utterance of "I moved to the Bay Area in 1974" as I would have said using the same sentence five or ten years ago. But then I had older non-Norwegian colleagues, and couldn't have identified myself in this way. The proposed translation would have been false. Further, if I now explicitly say, "Stanford's oldest non-Norwegian philosopher moved to The Bay Area in 1974," the self-knowledge expressed by I saying "*I* moved to The Bay Area in 1974" would be missing. I might know that Stanford's oldest non-Norwegian philosopher moved to the Bay Area in 1974, without realizing that *I* did so. We might, following Russell, try to replace "I" with something like "the person having *this* thought now." But we would have simply traded one indexical, "I," for two, "this thought" and "now." It's very hard to come up with any plausible candidate to translate "I" that does not employ an indexical; we'll look at the reasons for this below.

The eliminative approach has seldom been defended; it is important only as what philosophers have perhaps had in mind, who ignored the phenomenon of indexicality.

A second approach I call *reductive*. Reichenbach's "token-reflexive" theory is an example (Reichenbach, 1947). Reichenbach reduced all indexicality to one expression, 'this*,' which means roughly, "this very token." So 'I' means "the speaker of this*," 'you' means "the addressee of the speaker of this*" and so forth. Alternatively, one might suppose, following Castañeda (1999, esp. chapters 1 and 2), that all indexicals can be defined in terms of 'I' and 'now.' 'You,' for example, means "the person I am addressing now" and 'here' means "the location I am now in." Such reductive approaches allow translation into a formal language based on the predicate calculus, which in its standard form has no provision for context relativity, with a minimal amount of change.

From the last part of the last century, however, the idea that translation into the predicate calculus takes care of semantics has waned, in favor of the idea that we should develop semantics for languages that can treat problematic expressions on their own terms. Richer formal languages, in particular modal and intensional logics, were developed. And context-sensitive expressions, like indexicals, came to be seen as rather central parts of language, rather that outliers to be ignored or kept to a minimum. In David Kaplan's theory (Kaplan, 1989), the most influential account of indexicality, indexicals are full-fledged parts of an intensional language and are given a semantics directly, rather than by translation.

Kaplan eschews utterances in his formal theory, in favor of *sentences in context*. A context, in Kaplan's technical sense, is a sequence of an agent, location, time, and world, where the agent is in the location at the time in the world. Expressions have *characters*, which are functions from contexts to *contents*. Contents are propositions and propositional constituents. So the character of 'I' is a function from contexts to the agent of the context. The character of "I moved to The Bay Area in 1974" is a function from a context to the proposition that the agent of the context moved to The Bay Area in 1974, that is, in the case of my utterance, the proposition that JP moved to The Bay Area in 1974. Thus suppose Michael Bratman and I each say truly, "I moved to the Bay Area in 1974." Our utterances have different *contents*, they express different *propositions*, both true as it happens.

A word about propositions. Propositions are abstract objects that encode truth-conditions, and are usually taken to be what 'that'-clauses stand for in statements like "Michael said that he was born in the Bay Area in 1974." *Qualitative propositions* rely only on properties and relations to encode truth-conditions: such propositions specify the patterns of instantiation

and co-instantiation needed for truth. *Singular propositions* allow particular individuals to do the instantiating and co-instantiating. Thus, if we take propositions to be sets of possible worlds, the singular proposition that Michael Bratman lives in the Bay Area would be the set of worlds in which Bratman himself instantiates the property of living in the Bay Area, whatever he is called, and whatever his most distinctive properties might be, in those worlds. It is true because the actual world is one of these worlds. Another conception of propositions is as sequences of properties and objects, in this case the sequence: <*living in the Bay Area*, Bratman>. The proposition is true because Bratman has that property. Many of us were convinced of the need to recognize singular propositions, conceived of in one way or another, by considerations about *rigid designation* and *direct reference* which I discuss below in §7. Others remain skeptical.[5]

Given that Bratman and I express singular propositions, they seem to be the same singular propositions we could have expressed by saying, respectively, "John Perry moved to The Bay Area in 1974," and "Michael Bratman moved to The Bay Area in 1974." The quite different ways of referring to ourselves, with 'I' or with our names, seem to be lost at the level of the proposition expressed, an issue I deal with below in §4.

3 The Semantics of Indexicals

The theory I develop here is inspired by Kaplan's approach, but has evolved in ways that incorporate significant differences (see Perry, 2011; forthcoming b). Most important is the explicit inclusion of utterances in the theory. To understand the pragmatics and cognitive significance of indexicals, we need to understand how the properties of utterances – particular episodes that are part of the causal realm – interact with other sorts of episodes, in particular cognitive episodes. For this purpose it is useful to have utterances in our theory.

The difference is a bit subtle. In Kaplan's formal theory, we have "sentences in contexts" rather than utterances. Suppose I say, at some time in the afternoon on November 29, here in Palo Alto, "The San Francisco Warriors play tomorrow." On Kaplan's theory we have the context: <JP, Palo Alto, November 29>. This context, plus the sentence I used, give us a content: that the Warriors play on November 30.

Contexts are clearly inspired by the nature of utterances. Utterances involve a speaker uttering an expression at a locations and time. From the point of view of developing a logic of indexicals, Kaplan finds it useful to abstract from the *uttering*. Instead of an utterance we have a context – agent, location, time, and world – and an expression. The combination of expression and context captures key facts about utterances, and so can be used to model them. But we can assign contents to the combination of context and expression even if there is no utterance – where the *agent* of the context isn't a *speaker* at the time and location in the worlds under consideration.

On this approach, the relation between the utterances and the elements of context are not dealt with in the theory. We *model* utterances as sentences in contexts, and then the theory takes over.

But for certain purposes, it is helpful to have utterances within the theory. Consider a belief an utterance that expresses it. Here we have a causal relation between a mental state and an intentional act and a content relation between the two. A theory that seeks to understand this complex relation, involving both cause and content, needs to be able to explicitly recognize the states and events that stand in the complex relations.

Suppose, on the 28th of the month, I leave the message, "The Warriors play tomorrow" on my daughter's answering machine. She doesn't check her answering machine, however, until the next day, the 29th. She interprets the recorded message she hears as meaningful, because she takes it to be the result of an intentional utterance. To correctly interpret it, she has to figure out *when* the utterance was made. Perhaps she gets this wrong, and thinks my call occurred on the same day she heard it and so wrongly takes it that the Warriors play on the 30th, rather than the 29th, as I intended to convey. With written communication, and recorded communication, the token produced by an utterance is not always perceived at the time of the utterance. The hearer or reader needs to make inferences to figure out the time of the utterance (or the speaker, or the location) to correctly interpret indexicals. This reasoning is based on the nature of utterances, their effects, and so on. Thus to understand my daughter's reasoning, and why the message I left was perhaps a bit inept, it is useful, at least, to have utterances in our theory.

Kaplan's *characters* are functions from contexts to referents associated with expressions. A character is a function from contexts to appropriate referents, that turns on the elements of context. For example, 'tomorrow' at *c* refers to the day after the day that includes the time of *c*.

What I call *roles* are similar to characters. Expressions provide a function from *utterances* to referents, that in the case of indexicals, turn on the speaker, location, and time of the utterance. So, an utterance *u* of 'tomorrow' refers to the day after the day that includes the time of *u*.

Metaphysically, the difference is a bit bigger than it sounds. Utterances are concrete events with many properties, including causes and effects. So, having utterances in the theory gives us a link to the mental events and states that lead to utterances, and their real and intended effects – the stuff of pragmatics. A context is an abstract object, a set-theoretical sequence of agent, location, time (and world), with no causes and no effects.

But, in practice, the difference is less than it sounds. Most philosophers use Kaplan's theory to think about utterances, rather than to prove theorems in logic. My approach makes explicit what is usually implicit in such applications of his account.

I assume that an utterance is an event or episode that lasts for a (relatively short) interval of time, and has a speaker who makes use of an expression, and a location. So, for each utterance *u* we have an expression E_u, a speaker, S_u, a time, T_u, and a location L_u. The location of the utterance is the location where the speaker uses the expression at the time.

Let *R-α* be the role associated with expression α. *R-α* is a (possibly partial) function from an utterance of α to its referent. The function will depend on some combination of the speaker, time, and location of the utterance. Since the location is determined by the speaker and time, we can set it aside when not relevant. So we have, as our preliminary analysis,

> The reference of an utterance *u* of an indexical α is the value of the associated role *R-α* with the speaker and time of *u* as arguments:
> The reference of an utterance *u* of α = *R*-α(S_u, T_u).

4 Cognitive Significance and Pragmatics

Suppose I say, "You look tired now" to Dikran at a time I'll call '**t**.' Call this utterance **u**. We can give three different, but consistent, truth-conditions for **u**:

E-conditions: **u** is true iff
$\exists x, t$ such that

(i) $x = R\text{-you}(S_u, T_u)$
(ii) $t = R\text{-now}(S_u, T_u)$
(iii) x looks tired at t.

I call these "E-conditions" because they are conditions on the utterance, that is the *Episode*.

S-conditions: Given that JP is the speaker of **u** and **t** is the time of **u**, **u** is true iff $\exists x, t$ such that

(i) $x = R\text{-you}(\text{JP}, \mathbf{t})$
(ii) $t = R\text{-now}(\text{JP}, \mathbf{t})$
(iii) x looks tired at t.

I call these "S-conditions" because they are conditions on the *Speaker* (and time) of the episode.

O-conditions: Given that JP is the speaker of **u**, **t** is the time of **u**, Dikran = R-you(JP, **t**) and **t** = R-now(JP, **t**), **u** is true iff:

Dikran looks tired at **t**.

I call these "O-conditions" because they put conditions on the *Objects* that the speaker is referring to and talking about.

O-conditions provide singular propositions, and correspond to Kaplan's *contents*. We would usually take what I said to be the proposition that Dikran looks tired at **t.** If Dikran were to say, "Yes, I look tired now," we would take him to have said the same thing that I did. And if someone were to say, "JP said that Dikran looked tired at **t**," we would take that as an accurate report of what I said. Dikran is referred to in three different ways, but the O-conditions, and the singular propositions they determine, are the same.

The level of O-conditions gets at *what else* has to be the case, for an utterance *u* to be true, given the reference-determining facts. This level is important because the reference-determining facts are often common knowledge. The O-conditions get at the additional or *incremental* information provided by the utterance. This importance is reflected in our practice of treating the three utterances as "saying the same thing."

O-conditions obscure differences among the three utterances, however, which are important in understanding the cognitive significance of utterances and their *pragmatics* – how they are used in communication. S-conditions and E-conditions are useful at keeping track of these differences; explicitly considering them is a second departure from Kaplan's approach.

Suppose that on December 5 I ask Dikran when the next meeting of our Questions Group is. As it happens, it is scheduled to meet that very day. He can answer me truly in two different ways:

"The next meeting is today"
"The next meeting is December 5"

Since "today," uttered on December 5, and "December 5," both refer to the same day, we *can* say that the two remarks would have the same truth-conditions: that the next meeting is December 5.

But the two remarks have different *cognitive significance*. That is, the speaker's beliefs that motivate the remarks, and the beliefs the speaker can expect the credulous hearer to acquire, may differ. What I would learn from the first differs from what I would learn from the second, at least if, as usual, I didn't know what day it was. In that case, the first would be more helpful. And Dikran might have been quite sure that the first remark was true, even if he didn't know what day it was, and so was not in a position to make the second remark.

We can get at the difference at the level of S-conditions. The first remark is true if the meeting is to occur on the same day that Dikran and I are conversing. So it provides me with the information I need for timely preparation for the meeting, even if I don't know what the date is. The second provides me with this information only if I already know that today is December 5. On the other hand, if I wanted to write down the day of my meeting on my calendar, Dikran's first utterance wouldn't give me all the information needed, while his second would.

The roles that are exploited by referring expressions are often associated with what I call *epistemic* and *pragmatic* methods (see Perry, 2011). There are ways of finding out more about the day referred to as 'today' that one can only employ on that day: look around and see what is happening, remember what has happened since the day started, and wait and see what else happens before the day ends. There is a way of finding out about the day referred to as 'December 5.' Look on your calendar at the cell with that date as a label, and see what happened, or is expected to happen, on that day.

Similarly, there are ways of acting, or developing plans for action, that are appropriate for days referred to as 'today' and 'tomorrow.' Dikran's first remark tells me I'd better start getting ready for the meeting. With his second remark, the appropriate action seems to be to enter the meeting on my calendar in the appropriate cell, and then figure out whether December 5 is today, or tomorrow, or next week, and develop a plan for getting ready.

As the example suggests, the way we use expressions, their pragmatics, is responsive to the utterance-relative roles associated with the expressions and the epistemic and pragmatic methods connected with those roles. If Dikran wants me to get ready, and is aware of my usual ignorance of what day it is, he would be remiss if he made the second remark rather than the first.

For another example, suppose it's January 16, 2015, and I want to tell Dikran that it's my 72nd birthday. I could say,

> "I turn 72 today"
> or
> "John Perry turns 72 today"

In each case, the way I refer to the objects I am talking about – myself and January 16, 2015 – contains information about them. Dikran knows that my utterance is true if the person I am referring to is 72 on the day I refer to. By referring to this person as 'I,' I provide a second mode of presentation or channel of information for this person. Dikran will realize:

> The person referred to by the utterance I am hearing = the speaker of that utterance = the person sitting across from me, and with whom I am talking

Suppose I'm not talking to Dikran, who knows me and knows my name, but a stranger, who asks me why I look so morose. "I am 72 years old today," does fine as a helpful explanation. "John Perry turns 72 on January 16, 2015," or even "John Perry turns 72 today" would just be puzzling. I don't look a day over, say, 68, so it might not occur to the stranger that I am talking about myself. The natural response might be, "Well, who is John Perry, and why feel sad that he's getting old?"

Now if I said, "John Perry turns 72 today," to Dikran, he could respond appropriately since he knows my name. But my statement would be a bit odd. This is because I am putting an unnecessary cognitive demand on Dikran. To respond appropriately, he needs to recognize me and remember my name. No doubt he would, but why require the extra steps, when the indexical formulation gives him all the information required?

Charles DeGaulle had the habit of referring to himself in the third person, as does Bob Dole, Bill Clinton's opponent in the 1996 U.S. presidential election. At a political rally in Philadelphia, while campaigning against Clinton, Dole said, probably alluding to Clinton's treatment of White House interns,

> If something happened along the route and you had to leave your children with Bob Dole or Bill Clinton, I think you would probably leave them with Bob Dole.

New York Times columnist Ellen Goodman's commented,

> I am not at all sure that I'd want to leave my children with someone who talks about himself in the third person. [6]

Goodman found Dole's utterance odd, probably rather pretentious. Dole's way of putting his point assumed that everyone who heard him knew that 'Bob Dole' was his name. Even though the assumption was doubtless true or nearly so, it still sounds pretentious and self-important. And, even given my well-know humility, Dikran might have the same reaction if I started referring to myself in the third person in conversations with him.

On the other hand, suppose I call Dikran on the telephone. "Who is this," he asks. "It's me," I reply. This may be unhelpful, if he doesn't recognize my voice, and in any case will strike him as annoying and a bit pretentious. To carry on an intelligent conversation, he needs to know more about the person on the other end of the line than merely that he is the person on the other end of the line. He needs access to the information about me he associates with the name 'John Perry,' and to be helpful I should refer to myself in a way that supplies it.

The suggestion, then, is that one important aspect of the pragmatics of indexicals is that referring to something indexically can open new "channels of information" about the things referred to, and indexicals are appropriate when these channels are relevant, and inappropriate when they are not. To understand how this works, we need to consider S-conditions and E-conditions and not just O-conditions. This idea is developed in my book with Kepa Korta, *Critical Pragmatics* (Korta and Perry, 2011).

5 Two Distinctions

Things are often a bit more complicated than envisaged by our preliminary theory, and these complications provide some ways of categorizing indexicals. I classify indexicals by two criteria, whether they are *automatic* or *discretionary*, and whether their reference

Table 38.1 Types of indexicals.

	Narrow	*Wide*
Automatic	'I,' 'today,' 'yesterday,' 'tomorrow'	'yea'
Discretionary	'here,' 'there,' 'now,' 'then'	'this,' 'that,' 'this building,' 'that man,' 'he,' 'she'

depends on narrower or wider circumstances of utterance. Table 38.1 includes the paradigms and some others. The reference of discretionary indexicals depends on the speaker's intentions in ways not yet provided for. The utterance-relative roles associated with them *constrain*, but do not completely determine, the referent.

Of course, with all expressions the intention to use them with their ordinary meanings is relevant. However, it seems that with a word like 'I,' no further intention is relevant to determining the referent. If I am speaking English, 'I' refers to me when I use it. The indexicals 'now' and 'here' seem at first glance as automatic as 'I.' But with 'now' there is a question of how long an interval of time is counted as the present moment; with 'here' there is a question of how much of the surrounding territory is included. The speaker has some discretion in what an utterance of these expressions stands for.

Suppose I say, "Now that the Supreme Court has decided that corporations have the right of free speech, campaign finance reform is hopeless." The period of time I refer to includes the moment of my utterance, but is not limited to that; it is a period that begins more or less when the court decided the Citizens United case, and will continue until their decision is changed, or perhaps reversed by amendment. In contrast, if my wife asks when the TV show *Downton Abbey* starts, in order to plan her evening, and I say "now," I'll have a much shorter interval in mind. Utterances of 'here' behave similarly.

'Today' seems automatic, and that's how I've listed it. But to deal with certain cases, we'd have to demote it to discretionary. Suppose I send an email to an editor in Paris concerning an overdue manuscript. "You will get it today," I write. To fulfill my promise, I have to send the manuscript on a day that includes the time of my message, that is, a 24-hour period from midnight to midnight that includes the time of the utterance. But midnight Paris time, or midnight California time? The editor hopes I mean the former, and a more diligent author might have had that intention. I probably would mean "today" California-time, giving myself a few extra hours, and count on the editor realizing this too late to complain.

With discretionary indexicals, the associated utterance-relative roles *constrain* but do not fully determine reference. We need to alter the rules in a significant way. If 'now' can be used to refer to indefinitely many stretches of time including the moment of utterance, something else needs to account for why a speaker refers to one of the eligible stretches rather than another, and this burden seems to be carried by the speaker's intention.

For example:

> An utterance *u* of 'now' refers to stretch of time *t*, *iff t* includes T_u and the speaker intends to refer to *t*.
> An utterance *u* of 'here' refers to a region *r* iff *r* includes L_u and the speaker intends to refer to *r*.

Ordinarily such intentions will be rather vague. If I say, "it is snowing here," do I mean to refer to my neighborhood, or Palo Alto, or the Bay Area? It's possible that I don't have any

intention that determines among these alternatives, although it may be clear enough that I don't mean to include all of California.

Some indexicals are sensitive only to the *narrow* context, that is, the speaker, time, and location of the utterance. Others are sensitive to elements of the *wider* context. My favorite example is 'yea.' "The fish I caught was yea long," means that it was as long as the distance between my outstretched hands as I speak. This indexical, perhaps not that common outside of Nebraska, requires a demonstration on the part of the speaker, something in addition to the speaker, time, and location, so it is in the wide column of our chart. But, at least as I construe it, the speaker has no option but to refer to the distance demonstrated, so it is in the automatic row.

Kaplan included demonstratives among indexicals. With a simple demonstrative like 'that,' the speaker's intention, sometimes indicated with a demonstration, is relevant. The same speaker at the same time and place might say "that" to refer to any salient object, perhaps something clearly in view, or perhaps something already mentioned in discourse.

Pronouns like 'he' clearly have an indexical use; it seem synonomous with 'that man,' or nearly so. Dikran and I are talking about Obama; as we speak a man walks by wearing a motorcycle helmet. "He is ready for anything," I say. The wider circumstances determine that both Obama and the fellow walking by are salient, but not which of these salient persons I refer to; that depends on my intentions. So 'he,' like 'that man' goes is the cell for indexicals that are both wide and discretionary.

6 Indexical and Undexical Uses

Dikran and I are planning our evening. "Let's go to a local bar," he suggests. The adjective 'local' seems function indexically, amounting to pretty much the same as 'near here.' It seems that:

> An utterance u of 'local' refers to the region in the neighborhood of L_u.

But now suppose I tell Dikran of an upcoming trip to Ireland. "Everywhere you go, be sure to have a beer at the a local bar," he says. 'Local' isn't functioning indexically here. But it seems intuitively to have the same meaning as in the first example. What is going on?

'Local' is associated with the function, *the neighborhood of*, where the argument for the function is a location of the sort an individual occupies at a given time, and the value is a wider region that constitutes the neighborhood of that location. In Dikran's first remark, the argument for this relation is simply L_u, the location of his utterance u: we comply with his suggestion if we go to a bar that is in the neighborhood of the place where he makes his remark. But in the second remark, the argument is provided by the quantifier, 'everywhere.' He means, roughly,

> While you are in Ireland, if you are in a location l, have a beer at a bar in the neighborhood of l.

In the case of Dikran's second utterance, his use of 'local' doesn't refer to a single region determined by the location of his utterance. It functions as a complex variable. It takes the locations quantified over by "everywhere you go" as arguments, and returns the local neighborhood for each.

Finally, suppose Dikran says, one afternoon on campus, "Remember our trip to Copperopolis? There was a local bar that was quite rowdy." Here 'local' refers to the neighborhood of Copperopolis; the argument for the function *R-Local* is Copperopolis, not Stanford, the location of his utterance.

I shall say that a word like 'local' that *can* take the location (time, or speaker) of the utterance as the argument for the associated role has *indexical uses* and exhibits *indexicality*. If the same word can also pick up the argument in other ways, it has *undexical uses* (see Perry, forthcoming a).

Some indexicals seem to have undexical uses. It is natural to think of 'past,' 'present,' and 'future' as indexicals, referring to stretches of times before, at the same time as, and after the time of the utterance. But J. M. E. McTaggart said, early in the twentieth century, of Queen Anne's death, which occurred in 1714:

> It began by being a future event. It became every moment an event in the nearer future. At last it was present. Then it became past, and will always remain so, though every moment it becomes further and further past. (McTaggart, 1908, p. 460)

McTaggart clearly doesn't mean that if you go back far enough, Queen Anne's death occurred subsequent to his writing that paragraph in the early 1900s. He is using 'future' and 'past' undexically.

One might suppose this is an abuse of language permitted only to philosophers. But here is a remark from an 2014 internet discussion of concussions:

> After her concussion in 2005, my 15-year-old daughter was very worried about whether she could play soccer again in the near future.

The writer doesn't seem to have a philosophical agenda, but is clearly using 'future' for events subsequent to 2005, not 2014.

A familiar piece of parental advice goes,

> Never put off until tomorrow what you can do today.

Here the functions associated with 'today' and 'tomorrow' seem to pick up arguments from the quantifier 'never.' If my mother told me this on, say, January 20, 1948, she wouldn't mean merely to suggest that I do things on January 20 and not leave them until January 21, but that *whenever*, throughout the rest of my life, I find myself with a task to do on a certain day, I should do it that day rather than put it off until the next one.

David Kaplan's theory of indexicals doesn't allow for such undexical uses of indexicals; he calls them "monsters." Handling them within his system would seem to require quantifying over contexts, which he doesn't allow.

The present system can be more flexible, however, because we have utterances as part of the theory. Contexts as such play no official role in the theory; the work of being input arguments for the roles associated with indexicals falls to the objects that play the roles Speaker-of, Time-of, and Location-of relative to the utterance in question. We can take the utterance to be the *default* source of the arguments, while allowing for other uses, without quantifiying over contexts. In the case of my mother's advice, the variable assignment associated with the quantifier 'never' supplies the arguments. In the case of the soccer parent's remark, it is the time of the concussion in 2005.

So, for example, we can suppose that the default for 'tomorrow' is an indexical use, so an utterance *u* of 'tomorrow' refers to *R-Tom*(S_u, T_u). But the arguments for *R-Tom* can be supplied anaphorically, as with the remark by the parent of the injured soccer player. Or it can be supplied by a quantifer, as with my mother's advice.

Among paradigm indexicals, the default seems especially weak with temporal indexicals. 'Here' and 'there' also seem to permit undexical uses, as in "You never seem content to be here. You always want to be there." But it's hard to think of a convincing case with 'I.' I'll leave that as an excerise for the reader. If you have a good example, send me an email.

There are clear non-indexical uses of 'here,' as when one points to a spot on a map, and says, "We'll start our trip here." We might postulate an ambiguity, but it seems we might also treat such cases as undexical uses, without introducing a new meaning. The meaning in such uses is still *R-Here*. In the undexical uses, we refer to the region close to the location represented by the demonstrated spot on the map, rather than the location of the utterance itself.

I'll use the term *indexicality* for the expressions that are associated with a reference-fixing function that *can* take the speaker, time, and location of their utterance as arguments. I'll use *indexicals* for expressions that exhibit indexicality, and where the indexical use is the only use permitted, or the clear default in normal conversation. So, in my terminology, 'local' exhibits indexicality, but is not an indexical.

7 Tokens and Technology

I distinguish between utterances and tokens. In my use, utterances are events; they belong to the same general category as other episodes, like perceptions and thoughts, that give rise to them. More specifically they are acts. Tokens are things produced by utterances, of various sorts: sounds that travel from speaker to hearer, or, given the technology of writing, marks on paper.

Primordial conversation was face to face. This meant the time of utterance and the time of perception of the uttered token were, for all practical purposes, the same. The location of the speaker and the location of the hearer, on the other hand, could be relevantly different in some cases. There was a natural dichotomy between 'here' and 'there,' the first for the speaker's position, the second for the hearer's. Not so with 'now.' The contrast between 'now' and 'then' would not be between speaker's time and hearer's time, but time of utterance and some other salient time. Speakers and hearers shared their nows, but not always their heres, to put it undexically. Shouting and smoke signals allow communication at considerable distance, and the telephone takes that further – but the time of utterance and time of perception remain the same. With written language, however, the time of the utterance that produces a token and the time or times at which the token is perceived can be distant from one another.

The practice of copying gives us an important relation among tokens. There is the original, directly produced by the utterance, copies of it, copies of those copies, and so on. Certain properties persist along this relation. The token is evidence for the existence and nature of the utterance that produced it, and so evidence of the intentions of the speaker (by which I will include the writer except when noted). And the copies of that token also provide such evidence, although perhaps not with as much certainty. Other properties do not persist. Sherlock Holmes can tell from a note whether the writer was right- or

left-handed, but he can't tell that from a copy someone else made of the note. For certain legal purposes, the original is required.[7]

In Kaplan's theory 'I am here now' is a theorem in the logic of demonstratives. It does not express a necessary truth, true in every possible world, but it is true in every context. This is because Kaplan required the speaker of a context to be at the location of the context at the time of the context in the world of the context. In our utterance-based theory, every utterance of "I am here now" is true because of the nature of utterances: the speaker of the utterance is at the location of the utterance at the time of the utterance.

Kaplan devoloped his theory in the 1970s. By the 1980s, answering machines had proliferated, and "I am not here now" became an oft-heard and easily understood and believed message. Is there something wrong with Kaplan's theory? Or something wrong with the 1980s?

One might suppose that it has become conventional to refer to the time of listening to a recording with 'now.' "I am not here now" means more or less that the speaker is not at the place where the utterance was recorded at the time the listener hears the resulting token.

However, messages like

> I've got to leave now. I won't be here when you hear this recording. I'll try to call you back later.

in which the use of 'now' refers to the time of utterance, are permissible and intelligible. It seems to be the speaker's choice, whether to use 'now' for the time the recording is made or the time it is heard.

Stephano Predelli (1998) notes that the phenomenon in question pre-dates answering machines. Only the technology of leaving notes is required. Predelli's character Jones has to flee unexpectedly; he leaves his wife a note:

> [P] As you can see, I am not at home now. If you hurry, you'll catch the evening flight to Los Cabos. Meet me in six hours at the Hotel Cabo Real.

The token produced in this case is the note. Jones has a plan, that his wife see the note when she returns at 5 p.m. He uses 'now' to refer to that time, not to the time when he writes the note.

Again, we cannot simply suppose that there is a convention with notes to use 'now' for the time of token-perception. Jones could have written:

> [P′] I'm leaving now for Los Cabos. I'll have been gone for a long time by the time you read this when you get home. If you hurry, you'll catch the evening flight to Los Cabos, and can meet me by 11.

If Jones had written P′, the use of 'now' would have referred to the time he left the note.

There is an interesting and insightful literature on how to think about this. Here I will simply consider whether the idea of undexical uses of indexicals helps. The proposal is that with [P], the speaker uses 'now' undexically. The argument for *R*-now is the time of the perception of the note, not the time of its production. Jones thinks of this time descriptively: the time during which his wife will read the note. His wife thinks of this time as 'now,' used indexically. In [P′], however, 'now' is used in the default way; it is the time Jones thinks of as "now," used indexically, and his wife thinks of as "when my husband wrote the note."[8]

8 Demonstratives

I'll call 'this' and 'that' *simple demonstratives*. Phrases like 'this man' or 'that building,' which add a general term, I'll call *augmented demonstratives*. Jeff King (King, 2001) has argued that what he calls "complex demonstratives," phrases like 'that student who scored one hundred on the exam,' should be treated as quantifiers rather than as indexicals. King's arguments are subtle and complex, and I won't deal with them here, but focus on simple and augmented demonstratives.

It seems that a use of 'that building' will be used to refer to a building that a speaker has in mind and intends to refer to. Typically, at least, the speaker will expect his hearer or hearers to be able to pick out, one way or another, the building in question. I'll say the referent of a demonstrative expression will, in paradigm cases, be *salient* to both speaker and hearer. For example, Dikran and I are walking through the new Engineering Quad at Stanford, and I say, "I like the arches on that building." I might be referring to a building that we are both looking at; it is perceptually salient. If not, I may accompany my remark with a demonstration, pointing at the building I have in mind. Or, if there is only one building with arches, I might count on Dikran using common sense and the charitable assumption that what I say makes sense, and to look around until he sees it.

Back at the office, Dikran might say, "The arches on the building aren't much like the ones in the original quad." The building is not peceptually salient, but is *conversationally* salient; he is referring to the building we were talking about earlier. And there are many other ways an object might be salient, or easily become salient, in a way that makes it suitable to be referred to demonstratively. There is a "degree of freedom" with demonstratives, the expressions on our chart in the cell for indexicals that are both wide and discretionary, that is a bit different than with our paradigm indexicals; the speaker's intentions determine the type of salience relation (*Sal*) that is involved.

So our rule for 'this' demonstratives goes like this:

> An utterance u of 'This [that] F' refers to b iff
> There is a salience relation *Sal*, that S_u intends to exploit, and
> (a) $Sal(S_u, T_u) = b$
> (b) $F(b)$
> (c) b is relatively near to [far from] S_u at T_u, along the relevant dimension.

(Condition (c) is admittedly a somewhat lame attempt to get at the difference between 'this' and 'that,' but it's the best I can offer.)

When we use simple demonstratives, the kind of object in question is often obvious. If I had merely said, "I like the arches on that," it would have been pretty obvious that I was talking about a building. However, we can use 'this' and 'that' when we don't have much idea what sort of object we are referring to. Dikran and I hear a loud noise on our walk. "What was that?" I ask. "An explosion in a lab? Lightning? A car-crash?" I am asking about the cause of the noise we heard, but it's not clear that I am referring to the noise. "That was a noise" would seem an unhelpful reply on Dikran's part.

Suppose I offer this advice,

> If a philosophical problem keeps you awake at night, *that* problem is a good dissertation topic for you.

What I am saying amounts to:

> if there is a problem *x* such that *x* keeps you awake at night, *x* is a good dissertation topic for you.

We could treat 'that problem' in my remark as an undexical use of 'that problem.' The salience relation *Sal* is (roughly) being something that kept the subject of an episode of thinking awake the night before the time of the thought. You are the subject. The time is supplied by the quantifer. I am saying,

> For any time *t*, if there is a problem *x* such that *Sal*(you, *t*) = *x*, then *x* is a good dissertation topic for you.

9 Direct Reference

Important concepts in the theory of reference emerged in 1960s and 1970s. Saul Kripke (1980) claimed that proper names were *rigid designators* (see Chapter 36, NAMES AND RIGID DESIGNATION). This means that the name picks out the same object in every possible world. If I say, "If Hillary Clinton had been nominated in 2008, then Barack Obama would not have been President in 2009," I have said something true, because in the worlds similar to ours in which Clinton was nominated in 2008, Obama was not President in 2009. If I say, "If Hillary Clinton had been nominated in 2008, then the winner of the 2008 election would not have been President in 2009," I seem to have contradicted myself. Although 'Barack Obama' and 'the winner of the 2008 election' both, in fact, stand for Obama, the latter is not a rigid designator.

David Kaplan introduced a similar concept in *Demonstratives* (Kaplan, 1989), *direct reference*. The idea is that a name *directly* contributes its referent to the *content* of an utterance; rigid designation is the upshot of direct reference. Kaplan maintained that indexicals and demonstratives, like names, are directly referential. The word 'direct' can seem a bit misleading. When I use the indexical 'you' in a conversation with Dikran, I refer to Dikran in virtue of the fact that he is the person I am talking to; the connection between my use of 'you' and Dikran is not direct, but mediated by the fact that I am talkng to him. But Kaplan does not intend "direct" to mean that the *mechanism* of reference is *unmediated*. He means that, whatever complexity may be involved in the mechanism of reference, it is the referent that becomes a constituent of the proposition one expressses, rather than some identifying condition of it. The route from proposition to referent is direct.

Frege's picture contrasts with both Kripke's and Kaplan's. Frege (1892) did not countenance singular propositions; he recognized only qualitative propositions. That is, propositions encode truth-conditions by determing how properties and relations need to be instantiated and co-instantiated for truth; individuals are not among their constituents.[9]

When I say "Bill Clinton was President in 1995," Frege would suppose that I have some identifying condition of Bill Clinton in mind, and the proposition I express is that the person who uniquely satisfies this condition was President in 1995. Even though 'Bill Blythe' and 'Bill Clinton' are both names of Clinton, someone might think that Bill Clinton was President in 1995, but have no idea that Bill Blythe was. So, Frege would reason, it is a mistake to suppose that "Bill Clinton was President in 1995" and "Bill Blythe was President

in 1995" express the same proposition; the sentences have different cognitive significance that should be reflected in the propositions the sentences express.

Kripke, Donnellan (1972), and Kaplan offer convincing arguments that we express singular propositions; that is, such propositions get at what we normally take to be *what is said* by using names and indexicals. This leaves us with a dilemma. If they are right, how do we account for differences in cognitive signficance?

Frege wanted a single notion of content (*Gedanke*) to do two jobs. First, contents are pieces of information passed from person to person, and indeed generation to generation, by the use of language. Second, contents should capture the differences in cognitive significance that come from different ways of thinking of the same thing. But the jobs are different. To get a piece of information, we typically abstract from the different modes of presentation various individuals might have towards the object the information is about. This is what O-conditions get at. Cognitive significance is a matter for S-conditions and E-conditions. Frege's idea that there is a single level of truth-conditions that does both jobs is a mistake (Perry, forthcoming b).

10 A Problem about 'I' and 'Now'

Suppose early on February 16 you see an email from your friend Elwood:

[Preamble]
To: You
Time: February 15, 11 p.m.
From: Elwood Fritchey
[Message]
I am going to bed now.

On the present theory, you know that 'I' refers to the person who wrote the message – call it **m**. Similarly 'now' refers to the time **m** was written. So, just looking at the text, you know the E-conditions of its truth:

m is true iff $\exists x\ \exists t$ such that
$x = R\text{-I}(S_m, T_m)$ &
$t = R\text{-now}(S_m, T_m)$ &
x went to bed at t.

You can then figure out the S-conditions, by consulting the preamble:

m is true iff $\exists x\ \exists t$ such that
$x = R$-I(Elwood, 11 p.m., February 15) &
$t = R$-now(Elwood, 11 p.m., February 15) &
x went to bed at t.

In the case of 'I' and 'now,' the O-conditions follow immediately, at least if we ignore discretionary concerns about 'now':

m is true iff Elwood went to bed at 11 p.m., February 15.

So far, so good. But how about Elwood? Elwood, an English speaker, knows the E-conditions of his email. But how does he know that what he will say, with that email, is that **he** is going to bed at 11 p.m.? He could type the email, and look at the preamble his computer generates, as you did, to figure out which person and time were referred to with 'I' and 'now,' but that doesn't seem necessary.

Elwood might have no idea what day it is, or even what time of day it is, and still be quite sure that when he uses 'now' he is referring to the time at which he is writing and intends to go to bed. It seems he just needs to think of that time as "now." That means he has to think of it as the value of *R*-now for a certain time as argument. But that means, it seems, he must think of *that* time. But how is this to be explained on the present theory? When he thinks "now" it seems that the time he thinks of is the time that is the value of 'now' at the time of the thought. If the only way he can think of this time is as "now" then it seems he identifies the time referred to as

The t such that $t = R$-now(Elwood, now)

But how can this get him any closer to knowing the time to which he is referring? It seems we have a circle, on the verge of becoming a regress.

The solution to this problem lies in what I call "primitive knowledge." Any animal has the ability to pick up information perceptually about the time at which the perception occurs, and use that information in guiding actions taken at the time. A chicken sees a kernel of corn, and pecks at it. In my terminology, the chicken's perceptual state *concerns* the present time, but is not *about* it. The idea is that if we, as chicken-theorists, want to explain the success of the chicken's behavior, *we* would need to *refer* to the time in question. It picked up information about its surroundings *at that time*, and, thanks to the simple architecture of chickens, automatically pecked *at that same time*. The information it picked up perceptually concerned what things were like at a given time, which assured that pecking, *at that same time*, would result in ingesting a kernel of corn. But the chicken does not need to refer to the time at which this all takes place or to think about it. It needs neither indexicals like 'now,' nor the concepts required to distinguish one time from another. Its perceptions automatically provide information about the way things are around it at the time of perception; its perceptual states vary with whether the environment presents an edible kernel or not, but not with the time at which the kernel is presented or not; it is always the time of the perception. The chicken doesn't need to "think" *there is a kernel of corn now*, but simply, *there is a kernel*.

Our lives are a bit more complex than the average chicken. We do have a concept of *now* and the word 'now.' But, we, like the chicken, don't need them and the distinctions that underlie them for simple transactions, in which we act at a given time on information picked up perceptually at that time. We also have primitive knowledge about the present time.

However, unlike the chicken, we do have the requisite concepts and words and can bring them into the picture when needed. We are masters of "the logic of articulation" (Perry, 1986; Korta and Perry, 2011). I am hungry and see a sandwich. I think, *there is a sandwich on my plate*, and eat it. But, if relevant, I infer *there is a sandwich on my plate now*. It is this that makes my concept of *now* a concept of the present time. Similarly, if I know that the bus is coming at 11:15, and see on my watch that it is 11:15, I think *the bus is coming now*, which

in effect makes me think *the bus is coming*, in that it leads me to get ready to board the bus, just as if I had seen it.

So, back to Elwood. Elwood doesn't need to know what time it is to know that he is going to bed. And he doesn't need to know what time it is to know that he is thinking of the time when he thinks *now* and referring to that time if he says "now." He just needs to be aware of that time, in the way one is aware of the present moment, the moment occurring when one is doing the thinking.

Elwood most likely knows that he is Elwood Fritchey. But he might not. Perhaps he is suffering a bout of temporary amnesia. In one sense, he doesn't know to whom he refers with "I," or thinks of when he thinks *I*. But, in another sense, he does. Just as there are special ways of knowing about the present time – look and listen – there are special ways of knowing about yourself. You are the person whose environment you find out about when you look. You are the person whose headaches you feel. And Elwood is the person whose feelings of tiredness he experiences, and the person who forms the intention, as a result of those feelings, to go to bed.

Just as we have primitive knowledge about the present time, we have primitive knowledge about ourselves. The chicken doesn't need to keep track of *which* chicken it is, in order to harness the information it gets from perception to guide its pecking. And Elwood doesn't need to keep track of who is feeling tired, in order to form an intention that will get that very person into bed. So with 'I,' as with 'now,' the threatened regress ends in primitive knowledge. Elwood is the person whose states and environment Elwood learns about in the special ways one knows about oneself. The argument for his use of *R*-I is the person he knows about in this special way.

11 Conclusion

We noted above McTaggart's use of indexicals in his famous argument about time. In fact indexicals, for all their conversational utility and humble origins, seem indispensable in talking about philosophical topics. Try rewriting Descartes's *Meditations* without the first-person, or McTaggart's essay without the words 'past,' 'present,' and 'future.' The reason for this, I suggest, is the connection just considered, between indexicals like 'I' and 'now,' and our primitive but indispensable ways of picking up and using information about the environment we find ourselves in – what is going on around *me, now*. However simple and untechnical 'I' and 'now' may be, compared to words that embody great insights of science or philosophy, they still are words, that express ideas, and connect with complex thoughts words can express. But on the other side, they connect with transactions most indispensable to life: an organism picking up information about itself at a time and putting it to use to its own benefit.

Notes

1 Peirce discusses his distinction in many places. See Atkin (2013).

2 I use double quotes for quoting language and thought, and as scare-quotes; I use single quotes for mentioning expressions, and italics for introducing technical terms.

3 I use *reference* somewhat broadly, rather than confining it to what names and other singular noun phrases stand for.

4 Few such generalizations can withstand the imaginations of philosophers. See, for example, Daniel Dennett's brilliant essay, "Where am I?" (Dennett, 1978).
5 In Kaplan's theory, propositions are sets of world-time pairs, a complication I ignore. An indexical provides a constant intension, that is, a function that picks out the same object in every possible world.
6 Ellen Goodman, *Boston Globe*, April 15, 1996.
7 For an interesting discussion and some useful terminology, see Levy and Olson (1992).
8 On Varol Akman's view the word 'I' has the speaker as a default reference, but in certain circumstances 'I' can refer to others. In my chapter in the previous edition of this *Companion*, I expressed some doubts about his case. However, his distinction between standard and default uses eventually led to the theory of undexical uses developed here. See V. Akman (2002) and Perry (2006).
9 I am being a bit casual here. Frege used the term 'thought' more or less as 'proposition' is used now. He usually eschews talk of "properties" in favor of concepts, which are extensional, and senses, which are not.

Objects and Criteria of Identity

E. J. LOWE

1 Introduction

'Object' and 'criterion of identity' are philosophical terms of art whose application lies at a considerable theoretical remove from the surface phenomena of everyday linguistic usage. This partly explains their highly controversial status, for their point of application lies precisely where the concerns of linguists and philosophers of language merge with those of metaphysicians. The degree of controversy concerning these terms has indeed prompted some skepticism as to their utility (see, for example, Strawson, 1976), but a less pessimistic response would be to try to exercise greater care and discrimination in their use (cf. Lowe, 1989a). Both terms are undeniably slippery, especially 'object.' Our concern will be with the sense of 'object' in which it is interchangeable with 'thing,' but it is important to see that this only coincides with a restricted sense of 'thing.' For we seem to use the word 'thing' in both a narrow and a broad sense, the former associated with the free-standing use of the word and the latter with its use in combination with quantifying adjectives to form unitary quantifier expressions like 'something' and 'everything' (cf. Teichmann, 1992, pp. 15–16, 166–167). The difference is brought out by reflecting on the two non-equivalent sentences 'Every thing is a thing,' which is trivially true, and 'Everything is a thing,' which is metaphysically controversial. (The first sentence means 'Everything which is a thing is a thing,' and is trivial in just the way that 'Every horse is a horse' is trivial; the second sentence, by contrast, is controversial in rather the way that 'Everything is a horse' would be.) As we shall see, some philosophical answers to the question 'What is a thing?' effectively ignore or deny this distinction. My own view is that the distinction is indeed a genuine one, and that it is the narrower sense of 'thing' that is ontologically significant. What is crucial to the status of 'thinghood' in this narrower sense is, I consider, the possession of determinate identity-conditions (see §3 below). This is where the notion of a 'thing' or 'object' ties in with that of a *criterion of identity*, for one guarantee that something possesses determinate

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

identity-conditions is that it falls under a general concept which supplies a definite criterion of identity for its instances. (Such a concept may be classed as a 'sortal.')

As I have already implied, the term 'criterion of identity' is, unfortunately, itself the subject of considerable dispute. One problem is that candidates for this title typically take one or other of two quite different logical forms, whose difference turns on the mode of reference they involve to the objects for whose identity they provide a criterion (see §5). Some objects are such that a canonical mode of reference to them by *functional* expressions of a quite specific kind is available. For instance, to use a famous example of Frege's (Frege, 1953, pp. 74 f.), a particular *direction* may be canonically referred to as the direction *of* a particular line. (Any expression like this, of the form 'the F of x,' may be called a functional expression.) In this particular case the object in question is, of course, not a *physical* but a geometrical one, and this fact may encourage the thought that it is a peculiarity of those objects for which a functional mode of reference is canonical that they are in some sense *abstract* objects, with logico-mathematical objects like directions, shapes, numbers, and sets providing paradigm examples (cf. Dummett, 1981, p. 481). However, as we shall see, the distinction between 'abstract' and 'concrete' objects is itself a highly controversial one, and although it has indeed been argued that this distinction turns ultimately upon differences between the criteria of identity governing objects of these two broad categories (see §10), it certainly does not appear to be simply related to the distinction between those criteria which do and those which do not involve functional modes of reference to the objects they concern. (For one thing, we have indisputably 'abstract' objects like sets, for which a criterion of identity is available which does *not* involve a functional mode of reference to them.) My own view, I should say, is that the distinction I have alluded to between the two types of identity criteria is not, at root, one of fundamental philosophical importance, in the sense of reflecting any basic metaphysical, semantic, or epistemological distinction between the categories of objects to which they apply. This being so, however, one might expect to be able to supplant one or other type of criterion by the other, and I shall indeed try to show how such an expectation may be satisfied in specific cases (see §§7 and 8).

Of course, the very *existence* of abstract objects is itself a matter of considerable philosophical controversy, though it would be inappropriate to engage in it here (but see further Hale, 1987, and Teichmann, 1992, for very contrasting views). However, one should at least be clear as to what is *meant* by 'abstract object' before one debates whether or not anything answers to that description. The putative examples I have so far mentioned – all of them logico-mathematical – are at least provided with clear-cut and unimpeachable criteria of identity; but other putative examples like propositions, facts, and properties do not appear to be so favored. This puts pressure on the idea that propositions and the like possess determinate identity-conditions at all, and correspondingly that they qualify as 'objects' or 'things' (in my narrow sense). That may seem no great loss, until we come to reflect that we can, ostensibly at least, *quantify over* and *refer to* propositions, facts, and properties. However, perhaps we can plausibly represent such 'quantification' and 'reference' as convenient *façons de parler*, capable of being paraphrased away innocuously. I think that is correct, despite the fact that the strategy of paraphrastic elimination is one which must be handled with a good deal of caution, as we shall see (§3). But before we can tackle such issues, we need to examine the role which criteria of identity play in our talk about objects of the least controversial varieties.

2 Sortals and Counting

It is a familiar but nonetheless important philosophical point that an instruction simply to count how many *things* there are in a given room at a certain time is one that cannot be carried out: not because there will always be too many things to count, but because the instruction does not even make determinate sense in the absence of a specification of the *sorts* or *kinds* of things that are to be counted (cf. Geach, 1980, pp. 63 f.; Dummett, 1981, pp. 547 ff.; Wright, 1983, p. 3; Lowe, 1989b, pp. 10 ff.). It makes sense to ask how many *books* there are on a shelf, or how many *girls and boys* there are in a class, because in these cases an appropriate specification is supplied. But what exactly is the nature of such a specification, and what role does it play in conferring determinate sense on such a question? In brief, the point is this. If one is to *count* or *enumerate* items, one must at least be able to *identify* and *differentiate* them, because otherwise some things might be counted more than once. (Just what 'counting' *is* is something that we shall return to later, in §9.) For instance, if I count the books on a certain shelf, I must count each book just once, so that I must be clear as to what differentiates one book from another. A crucial point here is that what differentiates one A from another may not be the same as what differentiates one B from another (where 'A' and 'B' are sortal terms – or, as the linguists appropriately call them, *count nouns* – like 'book' and 'child') – and this is because different sortal concepts supply different *criteria of identity* for the individuals falling under them. A graphic example is provided by an ambiguity in the term 'book' itself, whereby it may either denote a kind of physical object made out of paper, glue, and thread or else a kind of abstract entity possessing certain semantic and syntactic properties. We might call an item of the former kind a 'copy' and an item of the latter kind a 'work.' On a given shelf there might be several copies 'of' the same work, and so the number of books on the shelf in the *former* sense of 'book' would be greater than the number of them there in the *latter* sense.

A further point which emerges from this example, and to which we must return, is that some sortals denote kinds of *concrete* object while others denote kinds of *abstract* object – a distinction of importance, but one whose definition is controversial (see §10). Observe, incidentally, that I spoke above as though items of the abstract kind denoted by the term 'work' might literally occupy a position in space, for instance, a place on a bookshelf; but we shall see later that such talk should perhaps be interpreted in a more roundabout way. (What about *kinds* themselves: are they objects, and if so are they abstract objects? Again, this is something to which we shall return.)

Yet another point emerging from the problem of counting is this: although one must specify what *sorts* of things are to be counted in order to render determinate an instruction to count, it would be wrong to suppose that one can only meaningfully count things of the same kind (cf. Bennett and Alston, 1984; Lowe, 1989b, p. 105). As an earlier example implied, one may count the *boys and girls* in a class, and these are not the same kinds. It is true that boys and girls are both *children*, but that is by the by: one could meaningfully count the *boys and books* in a room, even though there is no single kind (governed by a single criterion of identity) of which both boys and books are sub-kinds. What is crucial is that if one is to count the As and Bs, then (1) A and B must each supply determinate identity conditions for their instances and (2) A and B must be *disjoint* kinds, so that nothing can be an instance of both (for example, one cannot meaningfully be asked to count the *dogs and animals* in a room).

Finally, I should remark that the fact that a general term conveys a criterion of identity for items to which it applies is not a sufficient condition for it to be possible, even in principle, to *count* such items. For *mass* terms like 'gold' and 'water' appear to convey criteria of identity – one can meaningfully ask whether the gold in this room (which might be scattered about it in the form of dust) is *the same* as the gold which formerly composed a certain ornament – even though it makes no sense to ask *how many* gold things, or portions of gold, are currently present in this room, not least because any portion of gold contains other portions of gold as proper parts (see further Simons, 1987, pp. 153 ff.). (By contrast, it does make sense to ask *how much* gold there is in this room.) This shows that a criterion of identity is not exactly the same as a *principle of individuation*, though in the remainder of this chapter we shall chiefly be concerned with count nouns, for which this distinction does not emerge (but see further Woods, 1965). A principle of individuation, we may say, combines a criterion of *identity* with a principle of *unity*: countable items are singled out from others of their kind in a distinctive way that is determined by the sortal concept under which they fall, whereas portions of stuff can only be singled out in *ad hoc* ways, of which there are indefinitely many – as when a portion of gold is singled out as the gold composing a certain ring.

3 What Is an Object?

Of course, not all general terms are sortals, supplying a criterion of identity for items to which they apply: there are also 'adjectival' general terms (Geach) or 'characterizing' universals (Strawson), which supply no such criterion and are, indeed, applicable to things of many different kinds – for example, 'wise' and 'red thing' (see Geach, 1980, pp. 63 f.; Strawson, 1959, p. 168). 'Thing' itself is the most general such term, and is often used interchangeably with the term 'object,' both sometimes being dubbed '*dummy* sortals' (cf. Wiggins, 1980, pp. 63 f.). But what *is* an object, in the most general sense of that term? (I should perhaps stress that what we are seeking here is a satisfactory characterization of what is *meant* by 'object,' not a general criterion for the *existence* of objects of whatever type.) This question is apt to prove confusing. One popular answer, which I shall call the 'Linguistic Answer,' is that anything that can be referred to all – anything that can be made the *reference of a singular term* or be the *value of a variable of quantification* – is 'thing' or 'object' (cf. Frege, 1952a; 1953; Wright, 1983; Quine, 1953a; 1953b). Another possible answer, which I shall call the 'Metaphysical Answer,' is that the term 'object' properly applies to any item which enjoys determinate identity-conditions, and hence any item falling under some sortal concept supplying a criterion of identity for its instances – so that, by this account, a particular *book* (whether a 'copy' or a 'work') or a particular *boy* would qualify as paradigm examples of 'objects.' Now, it may be disputed whether these two answers really *are* different, in the sense of providing different extensions for the term 'object': for it may be contended that anything that can be referred to or quantified over must for that very reason fall under a sortal concept supplying a criterion of identity for its instances. A proponent of the Linguistic Answer endorsing this contention occupies a position which may be epitomized by the two Quinean dicta 'To be is to be the value of a variable' and 'No entity without identity' (see Quine, 1976; 1969; 1990, p. 52). However, the contention in question is certainly open to dispute (cf. Strawson, 1976). For instance, we may apparently refer to the *fact* that such-and-such or the *proposition* that so-and-so, and indeed we may ostensibly quantify over facts and propositions (and likewise over properties, relations, and so forth), but must

we therefore be able to provide *criteria of identity* for such items? It is at the very least highly debatable whether we can, in the light of the interminable philosophical disputes as to what those criteria might be. This is a suspicion which is confirmed by the observation that, although 'fact' and 'proposition' are both grammatically count nouns, there appear to be no principled ways of *enumerating* facts and propositions.

A relevant consideration here may be that apparent reference to and quantification over facts, propositions, and the like seem to be *eliminable by paraphrase*, whence it might be thought that our apparent inability to provide criteria of identity in such cases coincides neatly with the exposure of such 'reference' and 'quantification' as mere *façons de parler* or inflated uses of language. To illustrate these possibilities of paraphrase, instead of saying 'The fact that John was promoted pleased me greatly,' I might less sententiously say 'I was greatly pleased that John was promoted'; and I might paraphrase 'John knows something that I don't' (ostensibly quantifying over propositions) as 'John is somewise more knowledgeable than I am.' (It may be deemed significant that the expression 'somewise' in the latter sentence – admittedly rather an archaism, but none the worse for that – is an *adverb*, in contrast with the *noun* 'something' which figures in the sentence being paraphrased.)

However, there are dangers in putting too much weight upon such possibilities of paraphrase. For one thing, paraphrase is a symmetrical relation, so the fact that reference to or quantification over items of certain kind can apparently be eliminated by paraphrase provides by itself no guide as to *which* of the classes of sentences so related are to be regarded as 'mere' *façons de parler* (cf. Wright, 1983, pp. 25 ff.; but see also Teichmann, 1992, for a defense of the claim that a privileged direction of paraphrase may be discerned). Another point is that it may turn out to be possible to eliminate by paraphrase even reference to and quantification over such paradigm examples of objects as books and children (see, for example, Quine, 1966), but we obviously would not want to say in these cases that such a possibility threatened the status of such items as 'objects.' Certainly this would undermine the suggestion that there is a neat coincidence between cases in which reference to and quantification over items of a certain class are eliminable by paraphrase and cases in which such items cannot be provided with adequate criteria of identity.

The dialectical position we have arrived at now would seem to be as follows. If the Linguistic Answer is combined with an insistence that items referred to or quantified over must be provided with criteria of identity, it looks as though reference to and quantification over facts and propositions must be deemed *ersatz*, since such criteria do not appear to be forthcoming in these cases; however, the possibility of eliminating such reference and quantification by paraphrase provides, it seems, no independent confirmation of the *ersatz* status of such reference and quantification, since such elimination is possible even where criteria of identity *are* available. In the absence of any other independent confirmation, the judgment that such reference and quantification are *ersatz* looks suspiciously like an *ad hoc* maneuver to save the combined view at issue. On the other hand, if the Linguistic Answer is cut free of the demand for criteria of identity, it appears excessively liberal as regards the objects it is prepared to admit to our ontology. The moral which I am inclined to draw is that we should prefer the Metaphysical Answer to the question 'What is an object?' and reject the contention that the Linguistic Answer effectively determines the same extension for the term 'object,' on the grounds that it fails to determine that extension effectively at all. My point would be that the devices of reference and quantification are exploited with immense prodigality in natural language, and resist any principled division into 'genuine'

and 'spurious' (*ersatz*) cases save by appeal to extra-linguistic metaphysical considerations. *Given* the Metaphysical Answer, we are entitled to deny the status of 'objects' to facts and propositions (on the grounds that they lack determinate identity-conditions) and on *this* basis deem 'reference' to and 'quantification' over them mere *façons de parler*, supporting the latter claim by the provision of suitable modes of paraphrase.

4 Frege on Concepts and Objects

It would not do to leave the Linguistic Answer without some further discussion of the views of one of its most esteemed proponents, Gottlob Frege. For Frege, a crucial contrast is to be drawn between objects and *concepts*, the hallmark of the latter being their 'unsaturatedness' (see Frege, 1952a). (The term 'concept' has today a psychological ring which would be quite alien to Frege's intention; in more familiar terminology it may be said to cover both *properties* and *relations*.) In Frege's view, then, the object/concept distinction is a reflection of the linguistic distinction between *subject* and *predicate*. What he has in mind, however, is not the ordinary *grammatical*, but rather the *logical* distinction – the point being that not all grammatical subjects are object-denoting (for example, quantifier phrases, like 'some boy' and 'every book,' are not). So what sort of subject term is object-denoting, on this view? In a word, *names* (*Eigennamen*, in Frege's terminology). However, these must be very broadly construed to include not just ordinary proper names but also definite descriptions (in their 'referential' uses; see Donnellan, 1966), demonstratives, personal pronouns, and so forth. All 'singular terms,' then? Yes, but arguably more besides (even if Frege himself did not think so). For *plural* terms, like 'the books on my shelf' and 'the Joneses,' can function as logical subjects, and surely qualify as object-denoting (see Sharvy, 1980; Boolos, 1984; Lowe, 1991a). Moreover, we should not assume that all object-denoting terms denote *individual* objects, for there are *mass* terms and *kind* terms (like 'gold' and 'tiger,' respectively) which apparently qualify as object-denoting despite not denoting *individuals* (particulars) – rather, they denote *sorts* or *kinds* (of stuff or things; see Lowe, 1989b, pp. 138 ff., 199 ff.; 1991a).

Now sorts or kinds are universals, and therefore presumably *abstract* objects (of which more anon). But what about the adjectival or characterizing universals mentioned earlier: are *they* not likewise objects, at least according to the Fregean view now under examination? This is where we run into Frege's paradox of the concept *horse* (Frege, 1952a): though bearing in mind what I have just said, 'horse' is an ill-chosen example because it is very arguable that 'horse' *does* function as a name and denotes an abstract object, the horse kind; for it can function as a logical subject, as in 'Horses eat grass' and 'Horses are mammals,' which I for one *don't* see (in the way Frege did) as involving quantification over individuals (see Lowe, 1989b, pp. 138 ff.; 1991a). A better example, from my point of view, would be the concept (or, as we might more familiarly say, the property) *wise*. The point then is that '– is wise' functions as *a predicative* expression and so is not object-denoting by Frege's account, because what it expresses is 'unsaturated' (that is, demands 'completion' by an object to form a whole proposition). But if we try to *refer* to what it expresses (by speaking of 'the concept *wise*,' or 'the property of wisdom,' or even just 'what "– is wise" expresses'), then by Frege's own lights we only succeed, it seems, in referring to an *object* which perforce is *not* the concept in question, but a surrogate (see Dummett, 1981, pp. 211 ff.; Palmer, 1988, pp. 36 ff.). Quite what to make of this puzzle is far from clear, though

Frege's own attitude to it (namely, that language prevents us from saying what we want to here, but that we can still somehow get the appropriate message across: Frege, 1952a) certainly does not appear at all satisfactory. I confess I am strongly tempted to see the paradox as an artifact of the Linguistic Answer to the question 'What is an object?' and hence to regard it as a further consideration (though perhaps only a minor one) in favor of the Metaphysical Answer. (According to the Metaphysical Answer, of course, what – if anything – excludes properties like wisdom from the realm of objects is that they lack determinate identity-conditions.)

Rather than pursue this dispute further, however, it may be more profitable to build upon the common ground which clearly exists between an advocate of the Metaphysical Answer, like myself, and most proponents of the Linguistic Answer (namely, those who also subscribe, with Frege and Quine, to the view that reference to and quantification over any class of items presupposes the availability of criteria of identity for those items). This common ground is that to all intents and purposes we can take an object to be any item falling under a sortal concept which supplies a well-defined criterion of identity for its instances. Our next task, then, is to attend to certain difficulties attaching to the very idea of a criterion of identity.

5 Two Forms of Identity Criterion

The notion of a criterion of identity is one which, again, we owe largely to Frege (Frege, 1953, pp. 73 ff.), though we can find antecedents to it in ancient and medieval discussions of the *principium individuationis* (see, for example, Anscombe, 1981; Gracia, 1988) and in Locke's discussion of the idea of identity (Locke, 1975, pp. 328 ff.). Foremost, perhaps, amongst the difficulties attaching to this notion is the question of what *form* such a criterion may or should take. There are two paradigms to be found in the literature, which we may distinguish (using the convenient nomenclature of Timothy Williamson, 1990, pp. 145 ff.) as 'one-level' and 'two-level' identity criteria (see also Lowe, 1989a). Take the example of *sets*. A *one-level* criterion of identity for sets is provided by the Axiom of Extensionality, as follows:

(S1) $\forall x \forall y((\mathrm{Set}(x) \,\&\, \mathrm{Set}(y)) \rightarrow (x = y \leftrightarrow \forall z(z \in x \leftrightarrow z \in y)))$

In words: if x and y are sets, then x is identical with y if and only if x and y have the same members. A *two-level* criterion of identity for sets is provided by Frege's (fatal) Axiom V of the *Grundgesetze* (see Frege, 1952b, pp. 234 ff.; Wright, 1983, p. 155):

(S2) $\forall F \forall G(\{x: Fx\} = \{x: Gx\} \leftrightarrow \forall x(Fx \leftrightarrow Gx))$

In words: the set of Fs is identical with the set of Gs if and only if all and only Fs are Gs. This axiom was the source of notorious difficulty for Frege, because unless a suitable restriction on possible values of 'F' and 'G' is specified, Russell's paradox can be generated from it (see Frege, 1952b). Other well-known Fregean two-level criteria of identity are his criterion of identity for *directions* (Frege, 1953, pp. 74 f.):

(D2) $\forall x \forall y((\mathrm{Line}(x) \,\&\, \mathrm{Line}(y)) \rightarrow (dx = dy \leftrightarrow x // y))$

(the direction of line x is identical with the direction of line y if and only if lines x and y are parallel with one another) and his criterion of identity for *cardinal numbers* (Frege, 1953, pp. 73 f.):

(N2) $\forall F \forall G(Nx\colon Fx = Nx\colon Gx \leftrightarrow \exists R(\{x\colon Fx\}\ 1-1_{R}\ \{x\colon Gx\}))$

(the number of Fs is identical with the number of Gs if and only if the set of Fs is one-to-one correlated with the set of Gs).

The key formal differences between one-level and two-level identity criteria may be described as follows. One-level criteria explicitly quantify over objects of the sort for which they supply a criterion of identity, and state that criterion in terms of a biconditional, one side of which contains a simple expression of identity between such objects and the other side of which expresses an equivalence relation obtaining between those identified objects. By contrast, two-level criteria quantify over items of a *different* kind from that of the objects for which they supply a criterion of identity, and state that criterion in terms of a biconditional, one side of which contains an expression of identity between such objects in which they are referred to by means of *functional* terms relating them to items of the kind quantified over, and the other side of which expresses an equivalence relation obtaining between the items to which the identified objects are thus related.

A difficulty which can beset either form of identity criterion is that of *impredicativity*, which threatens to render such criteria viciously circular. (An impredicative criterion is one which involves "appeal to a totality that includes or depends on" the very objects whose identity is in question: Quine, 1985, p. 166.) It is important to recognize, however, that impredicativity does not *inevitably* give rise to vicious circularity. It doesn't, for instance, in the case of (S1), even if it is advanced in the context of 'pure' set theory of the Zermelo–Fraenkel type, in which all sets save the empty set only have other sets as members (see further Lowe, 1989c). But there certainly *can* be such circularity, as for instance in Donald Davidson's one-level criterion of identity for *events* (see Davidson, 1980; Quine, 1985; Lowe, 1989a; 1989c):

(E1) $\forall x \forall y((\text{Event}(x) \,\&\, \text{Event}(y)) \rightarrow$
$(x = y \leftrightarrow \forall z(\text{Event}(z) \rightarrow ((\text{Cause}(x, z) \leftrightarrow \text{Cause}(y, z)) \,\&\, (\text{Cause}(z, x) \leftrightarrow \text{Cause}(z, y))))))$

In words: if x and y are events, then x is identical with y if and only if x and y cause and are caused by the same events. This is circular inasmuch as what makes for sameness amongst events is precisely what a criterion of identity for events is supposed to convey, and yet a grasp of that is needed in order to understand what is expressed on the right-hand side of the main biconditional in (E1). (This is more obvious when (E1) is expressed in words as above than it is when logical symbolism is employed as in the formula (E1) itself: but there, too, we can see that the repetition of the variable 'z,' understood as taking events as its values, is equivalent to an expression of event-identity.) A similar problem does not beset the criterion of set identity (S1) despite the fact that sets may themselves be set-members, because according to standard set theory, at least, sets belong to a cumulative hierarchy in which (S1) fixes the identity of each set recursively, beginning with sets which contain only non-sets as members, or with just the empty set in the case of 'pure' set theory (see further Lowe, 1989c).

Certain difficulties peculiar to two-level criteria arise from the fact that they utilize *functional* expressions to refer to the objects for which they supply a criterion. One difficulty is that this limits their scope of application quite considerably, at least in the absence of further theorizing. For instance, we need to be able to employ other means of referring to numbers than expressions of the form 'the number of Fs' – not least the numerals '1,' '2,' '3,' and so on. Thus Frege's criterion (N2) doesn't of itself determine the truth-conditions of a statement like '1 + 2 = 3' or 'The number of books on my shelf is eighteen.' Another difficulty is that when we turn away from the sort of mathematical examples which interested Frege, we are often hard put to think of an appropriate two-level way of stating identity criteria. Consider, for instance, the problem of *personal* identity: the trouble is that there is no standard *functional* mode of referring to persons as there is to directions and numbers and sets. Directions are directions *of lines*, and numbers are numbers *of objects satisfying some condition*, as also are sets. But persons aren't at all obviously persons 'of' anything at all in this sense – in short, it isn't obvious what domain of entities ought to be invoked in order that an equivalence relation on *them* may be cited as a criterion of identity for persons (but see Williamson, 1990, pp. 116 ff., for a two-level proposal concerning personal identity).

Even setting aside the foregoing difficulties, which may not seem very serious, it is clear that the two-level approach to identity criteria contains a built-in limitation inasmuch as any such criterion presupposes the identity of items of one kind in providing a criterion of identity for those of another. Thus (D2) presupposes the identity of lines in providing a criterion of identity for directions, and (N2) presupposes the identity of sets in providing a criterion of identity for cardinal numbers. (By saying that (D2) 'presupposes the identity of' lines I mean, of course, that in the absence of a further criterion of identity for *lines* (D2) does not provide a fully informative account of what distinguishes one direction from another.) One-level criteria are not inherently subject to this limitation, which suggests that they will in any case have to be invoked at some stage whenever two-level criteria are themselves invoked. This inevitably provokes a query as to whether two-level criteria are really needed at all, that is, as to whether the work which they do might not be equally well effected by one-level criteria. For unless there are compelling reasons for supposing that two-level criteria provide an indispensable service, considerations of simplicity and parsimony urge us in the direction of regarding one-level criteria as constituting the canonical form. Before we explore this issue, however, one or two preliminary remarks are in order concerning the logical status and role of identity criteria quite generally.

6 The Logical Status and Role of Identity Criteria

The first thing to stress is that criteria of identity are to be thought of, for present purposes, as logico-metaphysical rather than heuristic or epistemic principles – they tell us, in Locke's words, "wherein identity consists" for objects of a given kind (Locke, 1975, p. 335), *not* how we may set about discovering the truth or falsehood of an identity statement concerning such objects; though, obviously, they will not be totally irrelevant to the latter sort of issue (cf. Lowe, 1989b, pp. 15 f.).

Second, identity criteria are not *definitions* – neither of *identity*, nor of *identity restricted to a certain sort or kind* (for identity is univocal), nor even of the *sortal terms* for which they supply criteria (cf. Lowe, 1989b, pp. 22 ff.; Williamson, 1990, pp. 148 ff.). Neither one-level nor two-level identity criteria are apt to provide definitions of the associated

sortals ('direction,' 'number,' and so forth). For two-level criteria, as Frege recognized (Frege, 1953, pp. 77 ff.), do not enable one to replace *all* occurrences of those sortals, only those in which they figure in functional expressions flanking an identity sign on both sides. And one-level criteria involve, as we have seen, reference to and indeed quantification over things of the very sort for which they provide a criterion, and accordingly presuppose some grasp of the associated sortals. (This is made quite explicit in the one-level criteria formulated above – (S1) and (E1) – in which the relevant sortal figures in the antecedent of the formula, instead of a restriction being imposed on the domain of quantification.) So, although it is true that criteria of identity can be construed as conveying semantic information about the sortal terms they relate to (and, certainly, a full grasp of the meaning of those sortal terms requires a grasp of their associated criteria of identity), they do not completely specify the meanings of those terms. This is a fact which, indeed, becomes obvious once it is realized that many *different* sortals are governed by the *same* criterion of identity. ('Cat' and 'dog,' for example, are so governed – for cats and dogs both being kinds of animal, they necessarily both share the criterion of identity governing the sortal 'animal': it would be hard indeed if 'that dog' and 'the animal in that cage' conveyed different identity criteria, given that they may refer to one and the same object.)

Third and finally, I should emphasize that it is not enough for a criterion of identity for As simply to state a logically necessary and sufficient condition for A-identity: it must state such a condition in an informative and, more particularly, a *non-circular* way – by which I mean that a grasp of A-identity must not already be needed in order to understand what is involved in the satisfaction of the condition in question (cf. Lowe, 1989b, pp. 20 f.). As we saw earlier, Davidson's one-level criterion of identity for events, (E1), fell foul of this requirement.

7 One-Level versus Two-Level Identity Criteria

Let us now return to the issue of whether two-level identity criteria are dispensable. One obvious thought is that they may be capable of reformulation in one-level style. (The reverse could not in general be true, in view of our remarks towards the end of §5.) Consider (D2), then, the Fregean criterion of identity for directions, which tells us that the direction of line x is identical with the direction of line y if and only if lines x and y are parallel with one another. Why not reconstrue this in one-level style as the principle that directions are identical just in case any lines of which they are the directions are parallel with one another (cf. Lowe, 1989a)? That is:

(D1) $\forall x \forall y((\text{Direction}(x) \,\&\, \text{Direction}(y)) \rightarrow$
$(x = y \leftrightarrow \forall w \forall z((\text{Line}(w) \,\&\, \text{Line}(z) \,\&\, \text{Of}(x, w) \,\&\, \text{Of}(y, z)) \rightarrow w /\!/ z)))$

It may be objected (cf. Williamson, 1990, pp. 146 f.) that (D1) cannot strictly say the same thing as (D2) because it exploits new terminology in the form of the expression 'Of' (which expresses the relation between a direction and a line of which it is the direction). But, first, exact synonymy is not our target anyway, or else there would be no real advantage in trying to 'reconstrue' two-level criteria in one-level terms; and, second, we might in any case urge that the meaning of 'Of' must be implicitly grasped by anyone who can understand the functional expression 'the direction of x,' which is symbolized in (D2) by 'dx.' Here, however, it may be

further objected that, indeed, 'Of(x, w)' in (D1) is *only* to be understood as a paraphrase for 'dw = x,' so that it is an illusion to suppose that (D1) really dispenses with such functional expressions (cf. Williamson, 1990, pp. 146 f.). But it is not at all clear to me that this suggestion is correct, and we have in any case noted already, in §3, that a possibility of paraphrase does not of itself establish semantic priority (because paraphrase is a symmetrical relation).

Other objections may perhaps be raised against the attempt to reconstrue (D2) as (D1), though I shall not pursue them here (but see further Lowe, 1991c). I must, however, reject Williamson's charge that the Fregean approach of (D2) can, whereas the one-level approach of (D1) cannot, explain why directions and lengths have *different* criteria of identity. According to Williamson, the explanation is that they do so 'because two lines can have the same direction and different lengths, or *vice versa*' (Williamson, 1991, p. 195). But in reality this is no explanation at all, for if it were correct parity of reasoning would require us to say that *heights* and *widths* must have different criteria of identity because two plane figures can have the same height and different widths or *vice versa*, yet heights and widths are both kinds of lengths, being vertical and horizontal lengths, respectively, and so must in fact share the *same* criterion of identity, namely, that of lengths in general. (Observe that this doesn't imply that any height can be *identified* with any width, any more than the fact that cats and dogs share the same criterion of identity implies that any cat can be identified with any dog.) As to the question of what, then, is the correct explanation for the fact that directions and lengths have different criteria of identity, I can only say that the search for an *explanation* of this sort of fact seems to me misplaced from the outset: criteria of identity are built into the very sense of sortal terms, so that to ask why things of the sort which a sortal term denotes are governed by the criterion which it conveys is comparable to asking, absurdly, why the sort of things which it denotes is the sort of things that it is.

The case of directions is not, however, of enough intrinsic importance for too much to hang upon it: Frege himself only introduced it for illustrative purposes. It would be more interesting and potentially fruitful to explore a more fundamental case, such as that of the criterion of identity for cardinal numbers. However, we should bear in mind that what is ultimately at issue is whether two-level identity criteria are dispensable, and to demonstrate that they are it is not necessary to show that they can always be *reconstrued* in one-level terms. Rather, it may suffice to show that we can always supply an adequate one-level criterion *in place of* any two-level criterion; for one criterion of identity is all we need for any given kind of objects, especially if we can also *derive* any correct two-level criterion from an adequate one-level criterion, perhaps with the aid of other necessary truths or definitions. (As we shall see, however, matters may not end quite there, since questions of epistemological and semantic priority may still remain outstanding.)

8 On the Identity of Cardinal Numbers

Consider, then, the case of cardinal numbers. (I should stress that in what follows we shall only be concerned, as Frege himself was, with cardinals no larger than the smallest transfinite cardinal.) What might a one-level criterion to replace Frege's (N2) look like? Here is a possibility:

(N1) $\forall x \forall y((\text{Number}(x) \,\&\, \text{Number}(y)) \rightarrow$
$(x = y \leftrightarrow \forall z(\text{Number}(z) \rightarrow (\text{Precede}(z,x) \leftrightarrow \text{Precede}(z,y)))))$

In words: if x and y are cardinal numbers, then x is identical with y if and only if all and only the cardinal numbers preceding x also precede y (precede, that is, in the series of cardinal numbers <0, 1, 2, 3, …>). Of course, (N1) is 'impredicative' – but only in the harmless way in which (S1) is. No vicious circularity ensues. Criterion (N1) serves to identify 0 unambiguously as the cardinal number which has no predecessors (compare the empty set), and to identify all succeeding cardinal numbers in a recursive fashion (thus 1 is the cardinal number which has as its sole predecessor the cardinal number which has no predecessors, that is, 0, and so on). It is indisputable that (N1) cannot of itself convey the meaning of the sortal term 'cardinal number' to anyone not yet possessed of the concept, and so cannot be taken as providing anything like a definition of this term; but that, as we have seen, should not be regarded as part of the function of a criterion of identity in any case.

An interesting question to raise now is this: Can we recover Frege's principle (N2) from (N1), supplemented with some further necessary truths or definitions? It appears that we can. First we need to define functional expressions of the sort used in (N2), 'Nx: Fx,' – 'the number of Fs.' The obvious thing to say is that the number of Fs is the cardinal number the set of whose predecessors is one-to-one correlated with the set of Fs. More formally, we may adopt the following definition:

(Def N) $\mathrm{Nx}\colon \mathrm{Fx} =_{\mathrm{df}} (\mathrm{iy})(\mathrm{Number}(\mathrm{y}) \,\&\, \exists \mathrm{R}(\{\mathrm{z}\colon \mathrm{Number}(\mathrm{z}) \,\&\, \mathrm{Precede}(\mathrm{z}, \mathrm{y})\}$
$1-1_{\mathrm{R}}\ \{\mathrm{x}\colon \mathrm{Fx}\}))$

In (Def N), I have used 'i' for Russell's definite description operator, so that '(iy)(… y …)' means 'the object y such that … y … ' and is analyzed in Russell's way, according to which (in plain English) 'The object y such that … y … is thus and so' is taken as being equivalent to 'There is one and only one object y such that … y … and y is thus and so.' If in addition to (Def N) we adopt the existence postulate that there is a cardinal number which is the number of Fs, for any condition F (subject to certain necessary restrictions discussed below), that is:

(N*) $\forall \mathrm{F} \exists \mathrm{y}(\mathrm{Number}(\mathrm{y}) \,\&\, \mathrm{Nx}\colon \mathrm{Fx} = \mathrm{y})$

then we are in a position to derive Frege's principle (N2). That is to say, (N1) in conjunction with (Def N) and (N*) entails (N2) (see Appendix 1). Or, in plain English, *given* that cardinal numbers are identical just in case they have the same predecessors, that the number of Fs is the cardinal number the set of whose predecessors is one-to-one correlated with the set of Fs, and that there is a cardinal number which is the number of Fs (and likewise a cardinal number which is the number of Gs), it *follows* that (Frege) the number of Fs is identical with the number of Gs if and only if the set of Fs and the set of Gs are one-to-one correlated.

9 Cardinal Numbers and Counting

But what precisely does the foregoing result serve to show? One's view of that will depend on what semantic and epistemological status one takes Frege's criterion (N2) to have. Is it a principle which has to be grasped by anyone aspiring to a basic knowledge of the cardinal numbers and so of elementary arithmetic? It is not clear to me that it is (but see Wright, 1983, pp. 117 ff., where an opposing view is expressed). Consider this: when children begin to learn about number they do so by learning to *count*. But what is 'counting'? It is a process

of establishing a one-to-one correlation between a set of objects (for instance, the books on a certain shelf) and the set of predecessors of a certain cardinal number: a task which is accomplished by singling out each object just once (often by pointing to it) and uttering a numeral in sequence until every object has been accounted for. In practice, of course, we don't say 'zero' but rather 'one' as we point to the first object, but that is purely a matter of convention: the upshot is still that when we have finished the counting process we 'reach' a number which is the number of the objects being counted, in the sense just defined – that is, a number the set of whose predecessors is one-to-one correlated with the set of objects in question. It is arbitrary whether by 'reaching 3' we mean uttering the sequence of numerals '0,' '1,' '2' or, as is conventional, uttering the sequence of numerals '1,' '2,' '3.' Now, counting provides us with a means whereby to establish the *equinumerosity* of two sets of objects – for example, the books on a shelf and the children in a class – relying on the fact that one-to-one correlation is transitive. Such equinumerosity *can* sometimes be established directly (for instance, by giving each child one and only one book), but often this is impractical. It seems to me that the realization that one-to-one-correlated sets of objects are *equinumerous* is a more sophisticated achievement than the simple ability to *count* sets of objects, and consequently that we should not expect a grasp of Frege's criterion of identity for cardinal numbers to lie at the heart of our basic understanding of number. Indeed, it is a possible objection to Frege's approach that it gives no immediate insight into the relationship between cardinal numbers and the process of counting which is central to a child's induction into a grasp of the numbers (for an extended discussion of this and related matters, not always consonant with the views expressed here, see Dummett, 1991, pp. 143 ff.).

This discussion of counting takes us back to some of the issues of §2. We remarked there that we can only meaningfully be asked to *count* objects when supplied with appropriate sortal specifications. We can now see more clearly why this is so. Counting a set of objects is a process of establishing a one-to-one correlation between those objects and the set of predecessors of a certain cardinal number, which is then designated as the number of that set of objects. But this process demands that each object is identifiable and differentiable from the others, and supplying a criterion of identity for each such object (which is what a sortal specification will convey) normally enables this demand to be met. However, this should not be taken to preclude us from saying that *there are* objects that are uncountable even in principle: for example, the portions of gold, or the red things, currently present in this room. Incidentally, I remarked earlier that a restriction would have to be placed upon the postulate that for any condition F there is a cardinal number which is the number of objects satisfying that condition ((N*) of §8). One reason why this is so is now clear: unless 'F' supplies a concept conveying a criterion of identity for each object falling under it, we cannot meaningfully assign those objects a number. Thus, where 'F' means 'book on this shelf,' there is no difficulty in supposing that there is a number which is the number of Fs: but not so where 'F' means 'red thing currently present in this room.' Observe, though, that even if 'F' *does* supply a concept conveying a criterion of identity for objects falling under it, this does not guarantee that there is such a thing as the number of Fs. For instance, 'set' supplies such a criterion in the form of (S1), and yet we know that there are 'too many' sets for there to be a number of them (though there may, of course, be a number of sets *meeting some further specified condition*, such as the number of 13-membered sets of cards that can be dealt from a 52-card pack: see, for example, Moore, 1990, pp. 147 ff.). Again, there is a criterion of identity governing portions of gold, and yet, as we saw in §2, no number can meaningfully be assigned to the portions of gold currently present in this room

(because mass terms like 'gold' fail to supply a principle of *unity* for their instances). So, stating an appropriate restriction on 'F' in (N*) is no simple matter. How best to handle this problem I shall discuss no further here, beyond saying that one obvious strategy which will serve the purposes to which we put (N*) earlier is to replace (N*) by:

(N**) $\forall F(\exists G \exists R(\{x: Fx\}\ 1 - 1_R\ \{x: Gx\}) \rightarrow \exists y(\text{Number}(y) \,\&\, Nx: Fx = y))$

In words: if the Fs are one-to-one correlated with the members of some set, then there is a cardinal number which is the number of Fs.

10 Abstract and Concrete Objects

One important issue which I have postponed until now is that of the distinction between 'abstract' and 'concrete' objects. I assume that numbers, sets, and directions are uncontroversially abstract, while books and children are indisputably concrete. Of course, it may be asked how I *know* that numbers are abstract, when nothing I have said about them so far determines what they are. Indeed, it has been argued that numbers *could not* be 'objects' at all (see Benacerraf, 1983; but see also Wright, 1983, pp. 117 ff., for criticism). My own view is that the natural numbers, at least, are *sorts* or *kinds* (of sets) and so *a fortiori* abstract (see Lowe, 1993). However, even if this is not accepted, perhaps we know enough about numbers to know that they would have to be abstract whatever they are – perhaps because there are too many of them for them to be concrete.

An obvious suggestion is that concrete objects are, while abstract objects are not, denizens of space-time (or, which perhaps amounts to the same thing, are/are not subject to causality: see, for example, Grossmann, 1992, p. 7). This has been queried, for instance by Bob Hale (1987, p. 49), on the grounds that objects such as *languages* are plausibly abstract and yet come into existence and undergo change and so presumably exist in time. (It won't do to classify them as abstract on the grounds that they *only* exist in time and not also in space – even if it were altogether plausible to say this of them – for we should want to classify Cartesian egos as 'concrete' despite ascribing only temporal, not spatial, existence to them.) Hale proposes instead, developing a suggestion of Harold Noonan's (see Noonan, 1976; 1978), that abstract objects can be distinguished by reference to certain features of the criteria of identity which govern them. Specifically, he proposes (Hale, 1987, p. 61):

(A4) F is an abstract sortal iff, for any R that grounds F, either
- R cannot hold between spatially located items at all or
- (R can hold between things which are spatially, but not temporally, separated

where R is an equivalence relation and R *grounds* F iff, for any statement of identity linking F-denoting terms, there is some statement to the effect that R holds among certain things, the truth of which is (logically) necessary and sufficient for the truth of that statement of F-identity (Hale, 1987, p. 59).

As an example of a grounding relation, Hale cites the relation of parallelism between lines, which qualifies as such 'in virtue of the fact that lines have identical directions iff they are parallel' (Hale, 1987, p. 59). From this it appears that Hale is thinking primarily in terms of two-level ('Fregean') rather than one-level identity criteria; though he acknowledges that

at least some sortals must be governed by one-level criteria (p. 57), and it is clear, indeed, that he intends (A4) to prescind from the distinction between one-level and two-level criteria.

Limitations of space prevent me from discussing the interesting reasoning behind Hale's ingenious proposal, but it appears in any case to be fatally flawed. This is most easily seen if one considers what it implies about *concrete* sortals (assuming that a sortal is 'concrete' if and only if it is not 'abstract'). Negating the right-hand side of (A4), we see that by Hale's account a sortal F qualifies as concrete iff there is some R that grounds F such that (i) R can hold between spatially located items and (ii) R cannot hold between things which are spatially, but not temporally, separated. Now consider the relation 'x and y coincide in their boundaries.' This is clearly a relation which serves to 'ground' the abstract sortal 'part of a geometrical figure,' for it is evident that if x and y are parts of a geometrical figure (for example, semicircular parts of a circle), then they are, of logical necessity, identical parts if and only if they coincide in their boundaries. However, this is a relation which *can* also hold between spatially located items (for instance, Switzerland coincides in its boundaries with itself), but cannot hold between things which are spatially separated (and so *a fortiori* cannot hold between things which are spatially, but not temporally, separated). By Hale's account, therefore, the sortal 'part of a geometrical figure' is wrongly classified as concrete.

However, rather than attempt to refurbish Hale's proposal, let us look again at the previous suggestion that abstract objects are those that are not denizens of space-time. The supposed difficulty was that objects like languages are plausibly abstract and yet also plausibly come into existence and undergo change. But perhaps we need to make a distinction, which can best be brought out by analogy with a related case: that of biological species. These too are said to come into existence and undergo change – indeed, that they do so is crucial to the theory of evolution. How then can species names denote universals, which are abstract entities and so, on the present proposal, timeless? The solution is to distinguish between biological *species*, which are *concrete individuals* consisting at any time of the mereological sum of their currently existing members (particular tigers or particular oaks), and biological *sorts* or *kinds*, which are universals instantiated by the members of those species (see Lowe, 1991a; and cf. Hull, 1976). Thus we can say that the horse *species* at one time did not exist and has evolved over millennia as its individual members have gradually taken on different morphological features, but that the *kind* horse which all these past and present individual horses instantiate never 'came into' existence and has not itself undergone change. In like manner, we may say that 'English,' construed as denoting a kind of language, does not refer to an ephemeral and changeable entity, but that what have come and gone and been subject to change are the concrete processes of linguistic communication which, over the centuries of English history, have all qualified as manifestations of English. On this view, inasmuch as 'English' denotes something abstract it denotes a *kind* (a universal), not an individual. To the extent that we happily identify various *sub-kinds* of English – such as American English and Old English – this view seems reasonable, since only kinds (not individuals) can have sub-kinds.

11 The Paradoxes of Identity over Time

This is a convenient place to address a final issue, which concerns the problem of *identity over time* and the paradoxes to which identity criteria often appear to give rise when time is brought into the picture. (There are also analogous *modal* paradoxes, which, however,

I shall not discuss here; but see Lowe, 1986; and Williamson, 1990, pp. 126 ff., as well as Chapter 40, RELATIVE IDENTITY.) The paradoxes arise because the identity criteria that we are intuitively led to adopt for various kinds of objects which persist through time permit these objects to change in certain respects while remaining numerically the same objects, and yet a series of small and acceptable changes can add up to a large change which we may intuitively feel to be incompatible with the retention of numerical identity for the object concerned. (Such paradoxes are, then, ostensibly a variety of sorites paradox: see Chapter 28, SORITES.)

In short: identity over time must be a *transitive* relation, and yet our intuitive identity criteria for objects persisting through time seem to rely on relations which are not strictly transitive.

For instance: we want to allow that a *ship* can persist identically through small changes in its component parts or in its overall design or structure, but a great many such successive changes may transform it into an object made of completely different materials put together in a completely different way; so that what we eventually have is no longer a ship at all, and so *a fortiori* not the *same* ship as the one we started with. Similar points have been made about *languages* (ignoring for the moment the bearing of my earlier denial that these may literally undergo change when conceived of as abstract entities). For example (see Williamson, 1990, p. 137), the language now spoken in Rome has, we may suppose, developed by small step-by-step changes from the language which was spoken in ancient Rome, such that no one of those changes amounted to the extinction of one language and the birth of a new one; and yet modern Italian is not numerically the same language, surely, as ancient Latin.

To cope with these problems we might attempt to refurbish what we take to be the intuitive identity criteria for artifacts like ships and languages, substituting strictly transitive relations for the non-transitive ones supposedly causing the trouble (cf. Williamson, 1990, pp. 139 ff.). But before taking such drastic action we should explore the possibility that the problems are spurious ones, arising from a confusion between the identity criteria for individuals falling under given sortal concepts and the conditions for the correct application of those sortals to individuals. We need, I suggest, to allow for the possibility of *metamorphosis* (see also Lowe, 1989b, pp. 103 f.), that is, a process whereby one and the same individual object can persist through a transformation from being an object of one sort A to being an object of another sort B, such that no object can *simultaneously* be both an A and a B. A logical restriction on such change is that A and B should supply the same criterion of identity for individuals instantiating them. But we have already noticed that very different sortal concepts can indeed convey the same identity criteria – for instance, the concepts *cat* and *dog* – and, indeed, that all sortals falling under the same higher-level sortals (as *cat* and *dog* both fall under *animal*) must, on pain of contradiction, supply the same identity criteria for individuals instantiating them. There can thus be no *logical* objection to the possibility of an individual animal surviving a change from being a cat to being a dog, even if such a transformation is *physically* impossible for biological reasons. In the case of artifacts like ships and languages such physical restraints are absent, and hence 'metamorphosis' may be expected to be a more common phenomenon amongst them. Thus, we can consistently react to the Italian/Latin example discussed earlier by saying that the same *individual language* has persisted identically in Rome from ancient to modern times, but that in the course of history it has changed from being an instance of the language-type *Latin* to being an instance of the language-type *Italian*, where these language-types are defined by certain

important lexical and syntactic features. (It should be observed that this reaction is consistent with my earlier proposal that to the extent that language-names like 'Latin' and 'Italian' denote abstract entities, they denote kinds or types rather than individuals; furthermore, it may be conceded that the boundary between Latin and Italian is not a sharp one, and even that some sub-kinds of Latin equally qualify as sub-kinds of Italian.) Similarly, one and the same individual artifact might change from being a ship to being a hotel, provided both sortals convey the same criterion of identity.

If this solution is correct, the lesson would be that it is an error to suppose that the criterion of identity for, say, artifacts of a given sort necessarily embodies within it a condition to the effect that such an individual can only persist *as an individual of that sort*. We need to distinguish between the diachronic *identity* conditions of individuals and the conditions for their persistence as individuals *of a given sort* (what we might call 'sortal persistence conditions'; cf. Lowe, 1991b, pp. 93 f.).

Once this distinction is drawn, I surmise, many of the supposed temporal paradoxes of identity will dissolve, since they present no challenge to the transitivity of identity, and only serve to demonstrate that 'metamorphosis' is possible and, indeed, quite common. (There do exist puzzle cases, like that of the ship of Theseus, which genuinely concern identity and cannot be handled in the way just proposed, but I believe that most such puzzles are independently soluble in a quite straightforward fashion: see Lowe, 1983.) Of course, it may be said that we were already familiar with the possibility of metamorphosis from the case of transformations like that of a caterpillar into a butterfly or that of a tadpole into an adult frog: but in fact such transformations are not true cases of metamorphosis as I presently understand that term, because count nouns like 'caterpillar' and 'tadpole' – like also 'boy' and 'sapling' – are what Wiggins has called phased sortals, describing an individual as it is during one period of its natural development (see Wiggins, 1980, p. 24). True metamorphosis, such as that of a cat into a dog or that of a human being into a frog, would not be a natural process; nor can 'cat' and 'human being' properly be called phased sortals.

Appendix: Informal Proof of (N2)

We want to show that (N2) follows from the conjunction of (N1), (Def N), and (N*) (see §8). Suppose, then, that

(1) $Nx: Fx = Nx: Gx$

that is, the number of Fs is identical with the number of Gs. Then, by (Def N), this implies that there is a number y, the set of whose predecessors is one-to-one correlated with the set of Fs, and a number w, the set of whose predecessors is one-to-one correlated with the set of Gs, and $y = w$. If $y = w$, then by (N1) y and w have exactly the same predecessors, and since we are given that the set of these predecessors is one-to-one correlated both with the set of Fs and with the set of Gs, it follows by the transitivity and symmetry of one-to-one correlation that the set of Fs is one-to-one correlated with the set of Gs, that is:

(2) $\exists R(\{x: Fx\}\ 1-1_R\ \{x: Gx\})$

So (2) follows from (1), and hence (N2) holds in the left-to-right direction. Next assume for the converse that (2) is true. Now, by (N*) we have that there is a number y, which is the

number of Fs, and a number w, which is the number of Gs. That is to say, by (Def N), we have that there is a number y, the set of whose predecessors is one-to-one correlated with the set of Fs, and also a number w, the set of whose predecessors is one-to-one correlated with the set of Gs. But by (2) we have that the set of Fs is one-to-one correlated with the set of Gs, whence it follows by the transitivity and symmetry of one-to-one correlation that the set of y's predecessors is one-to-one correlated with the set of w's predecessors. From this it follows that y and w have exactly the same predecessors, and consequently by (N1) that y and w are the same number. But y and w are, respectively, the number of Fs and the number of Gs, which are therefore also identical. So that (2) follows and consequently (N2) holds in the right-to-left direction. *QED*. (Note that the proof will equally go through with (N**) of §9 replacing (N*). It is crucial to the proof, incidentally, that – as stated at the beginning of §8 – we are concerned with cardinals no larger than the smallest transfinite cardinal (for background information see Moore, 1990, pp. 147 ff.))

Postscript

HAROLD NOONAN

This postscript takes its starting point from the common ground established in the main text (§4): that we can take an object to be any item falling under a sortal concept which supplies a well-defined criterion of identity for its instances. So our topic is the notion of a criterion of identity. David Lewis famously denied that there are problems about identity: "We do state … genuine problems in terms of identity. But we needn't state them

so. Therefore, they are not problems about identity" (Lewis, 1986, p. 193). In this postscript we provide an account, conforming to Lewis's dictum, of what one is providing when one gives a criterion of identity for objects of sort S.

There are, as noted in the main text, two forms of identity criteria in which an equivalence relation between objects (or entities of a higher level, concepts, for example) is specified as the criteria relation for the sort of object for which the criterion is being stated: one-level and two-level. A one-level criterion of identity for objects of sort S takes the form:

> If x is an S and y is an S then x = y iff Rxy
> for example, 'If x and y are sets then x is identical with y iff x and y have the same members.'

A two-level criterion for Ss takes the form (restricting ourselves to examples in which the criterial relation is one holding between objects):

> If x is an S* and y is an S* then dx = dy iff Rxy,
> For example, 'If x and y are lines then the direction of x is identical with the direction of y iff x and y are parallel.'

The key formal differences are noted in §5.

A two-level 'criterion of identity' is thus in the first place an implicit definition of a functor 'd' (e.g., 'the direction of') in terms of which a sortal predicate 'is an S' (e.g., 'is a direction') can be defined ('is a direction' = 'is the direction of some line'). Consistently with the two-level criterion of identity stated several distinct functions may be the reference of the functor 'd.' Hence, as stated in the text, two-level criteria are neither definitions of identity, nor of identity restricted to a certain sort (for identity is universal), nor even of the sortal terms for which they provide criteria. They merely constrain, but not to uniqueness, the possible referents that the functor 'd' represents and thus give a merely necessary condition for falling under the sortal predicate 'is an S' (when 'x is an S' is explained as equivalent to 'for some y, x is identical with dy').

Moreover, as noted in the text, and by Hale and Wright (2001), two-level criteria may be replaced by equivalent one-level criteria.

A one-level criterion of identity for things of sort S of the form above is equivalent to the conjunction of:

> If x is an S then Rxx

and

> If x is an S then if y is an S and Rxy then x = y.

Each of these gives a merely necessary condition for being an S (the second may also be viewed as giving, non-circularly, a necessary condition for a sortal concept to *be* the concept of an S: that there are not two R-related objects falling under that concept).The second of these says something about Ss which is not true of everything only if 'Rxy' does not entail 'x = y.'

Together these are equivalent to the proposition that every S is *the* S R-related to it. (Note that it may be that every S is the S R-related to that S, but it need not be the case, even though

every S is an S*, that every S* is the S* R-related to that S*, because some S*s are not R-related to themselves at all, or, even if Ss, are R-related to other S*s (see Cartwright, 1967; Noonan, 2009), so conclusions about non-membership of sorts (no Ss are S*s, not every S is an S*, e.g., no sets are properties, not every set is a property) cannot be safely drawn from premises about the distinctness of one-level criteria of identity.) The one-level criterion of identity for things of sort S thus again merely specifies a necessary condition for being an object of sort S.

A third possibility, not discussed in the main text, remains. This is that there are criteria of identity which are neither one-level nor two-level, but as it were, *zero*-level, because grasp of them does not consist in associating a criterial *relation* between objects (or any higher-level entities) with a sortal term at all. This is Dummett's proposal (1981; 1991). To understand a basic sortal term, like 'cat,' one must understand a statement of identification of the form 'this is the same cat as that' (uttered, for example, pointing first towards an ear and then a tail). But a statement of identification does not of itself involve any reference to objects since it is merely a crude relational predication (like 'this is darker than that') in which 'is the same cat as' does not stand for any relation at all. Reference to, and quantification over, objects takes place only at a higher level of language, and it is only at the higher level that one-level and two-level criteria of identity can be stated.

In addition to questions about criteria of identity *simpliciter* there are, for objects of some sorts, questions about criteria of identity over time.

It is a philosophical platitude, going back to Locke, that conditions of identity over time are sort-dependent. That is, they vary with the sort of object in question: "it being one thing to be the same person, another the same man, another the same substance, if *person*, *man* and *substance* stand for three different ideas" (Locke, 1975, essay II, xxvii.7). But as we will see, the specification of the conditions of identity over time for objects of sort S is just the specification of certain necessary conditions on being an S, those which constitute certain constraints on the history of a thing of sort S.

Recall the familiar philosophical puzzle of the statue and (sometime) coincident piece of clay. The usual argument for non-identity is that each can survive changes the other cannot. Our concept of a statue plausibly implies that *no statue can survive radical reshaping*. Our concept of a piece of clay plausibly implies that *any piece of clay must survive radical reshaping if all its matter is preserved in one coherent whole*. These propositions specify persistence conditions for statues and pieces of clay and, as they illustrate, these persistence conditions are of two types.

The proposition that no statue can undergo radical reshaping can be expressed as:

> If x is a statue then if the matter that constitutes x at t is radically reshaped at t, then x ceases to exist

– this specifies a 'passing away' condition for statues (this terminology comes from Penelope Mackie, personal communication).

The proposition that any piece of clay must survive radical reshaping in which all its matter is preserved in one coherent whole can be expressed as:

> If x is a piece of clay then if the matter that constitutes x at t is radically reshaped at t but preserved in one coherent mass, x survives

– this specifies a 'preservation' condition for pieces of clay.

Sortal concepts for persisting things are governed by such conditions because they constrain the histories of the things they apply to, and such constraints can always be expressed in the form:

If x is an S then if x exists at t and t* then Rxtt*

or in the form:

If x is an S then if Rxtt* and x exists at t then x exists at t*.

The 'passing-away' condition for statues is entailed by a principle of the first form (stating that a statue cannot have radically different shapes at different times) and the 'preservation condition' for pieces of clay is entailed by a principle of the second form (stating that if the matter composing a piece of clay at one time is in one coherent mass at that time and at another, whatever shape it is in the piece of clay exists at both times). We may call the first principle a 'passing away' principle and the second principle a 'preservation' principle.

Principles of these forms state necessary conditions for being a thing of sort S. A principle of the first form rules out certain changes in the history of an S. A principle of the second form rules out something's being an S if its history is not extensive enough; it tells us that if something is an S and there occur appropriately related events, one occurring at a time it exists, the second must also. Thus a principle of the second form imposes a certain 'maximality' condition on the concept of an S. What distinguishes sortal from non-sortal concepts under which persisting things fall (even from ones that apply to a thing at any time it exists, like *permanent bachelor*) is that they are governed by such principles.

So questions about criteria of identity over time can be rephrased as questions about necessary conditions of membership in a sort. One question we can ask, without mention of identity, is:

(Q1) What conditions *R* satisfy the following schema: (P1) if x is an S then if x exists at t and t*, Rxtt*?

Another is:

(Q2) What conditions R satisfy the following schema: (P2) if x is an S then if Rxtt* and x exists at t then x exists at t*?

To explain the criterion of identity over time for things of sort S is just to answer these two questions.

Thus all intelligible questions about the criterion of identity of things of sort S are equivalent to questions about the necessary conditions for being an object of sort S, in conformity with Lewis's dictum.

Relative Identity

HAROLD NOONAN

Introduction

A piece of bronze is shaped into a statue of Napoleon and then some time later melted down and shaped into a statue of Winston Churchill. Thus the same *piece of bronze* is, at different times, different *statues*. A ship undergoes a process of repair and replacement of parts so that eventually not a plank of the original remains. Thus the same *ship* is at different times two completely different *collections of planks*. Dr Jekyll drinks his potion and transforms himself into Mr Hyde. Thus the same *man*, at different times, is two different *persons* or *personalities*. In the zoo there are several individuals of the same species: Tiger Tim is the same *species of animal* as Tiger Tom, but a different *member* of the species. In the Trinity, the Father, the Son, and the Holy Ghost are the same *God*, but three different *Persons*.

These examples suggest that one and the same A may be different Bs, and hence that there is some sort of incompleteness or indefiniteness in the unqualified statement that x and y are the same, which needs to be eliminated by answering the question 'the same *what?*'

One way of making these vague thoughts more precise is by appeal to Geach's idea that *identity is relative* (see Geach, 1962; 1967 and subsequent references). Major contributions on the opposing side were those of Wiggins (1967; 1980) and Dummett (1973; 1981; 1991); views similar to Geach's were put forward by Quine (1963; 1973), Chisholm (1969; 1970; 1976), and Lewis (1976). In what follows I evaluate Geach's main claims and explore alternatives. I shall be considering Geach's claims solely as pertaining to the philosophy of language and philosophical logic, though much of the interest of the concept of relative identity concerns its applicability to other areas: the metaphysical controversy about *personal identity* and the debate in philosophical theology on the doctrine of the Trinity (see Geach, 1961; 1977; Cartwright, 1987; Van Inwagen, 1990; Cain, 1989). I shall set out Geach's views under six headings: (1) the non-existence of absolute identity, (2) the sortal relativity of identity, (3) the derelativization thesis, (4) the counting thesis, (5) the thesis of the irreducibility of restricted quantification, and (6) the 'name for an A' / 'name of an A' distinction.

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

I shall examine the main tenets of Geach and his opponents with regard to (1), (2), and (3), which are the core of his position. I begin with thesis (1).

The Non-existence of Absolute Identity

On the classical view of identity it is an equivalence relation which satisfies Leibniz's Law. These formal properties ensure that within any theory expressible by means of a fixed stock of predicates, quantifiers, and truth-functional connectives, any predicates which can be regarded as expressing identity will be extensionally equivalent. But they do not ensure that a two-place predicate does express identity within a theory, for its descriptive resources may not be rich enough to distinguish items between which the equivalence relation expressed by the predicate holds (Geach, 1972, pp. 238–247).

Geach calls a two-place predicate which has these formal properties in some theory an 'I-predicate' (actually 'I-predicable') relative to that theory. Relative to another, richer, theory the same predicate, interpreted in the same way, may not be an 'I-predicate.' If so, it will not, and did not, even in the poorer theory, express identity.

However, Quine has suggested that when a predicate is an I-predicate in some theory only because the language in which the theory is expressed does not allow one to distinguish items between which it holds, one can reinterpret its sentences so that the I-predicate in the newly interpreted theory does express identity. Each sentence will have just the same truth-conditions under the new interpretation and the old. Thus Quine suggests that in a language in which persons of the same income are indistinguishable its predicates may be reinterpreted so that the predicate which previously expressed *having the same income* comes now to express identity. The universe of discourse now consists of income groups, not people. The extension of an n-place predicate is a class of n-member sequences of income groups (see Quine, 1963, pp. 65–79). Any two-place predicate expressing an equivalence relation could be an I-predicate relative to some theory, and Quine's suggestion will be applicable to any such predicate.

In his (1967; reprinted in his 1972, pp. 238–247) Geach objects to Quine that applying this procedure leads to a 'baroque Meinongian ontology' inconsistent with Quine's own expressed preference for 'desert landscapes' (1972, p. 245). He concludes that the only tenable position is his own, that identity is relative.

To understand this we can begin by considering the following passages. In the first, Geach, as he often does, compares and contrasts his position with that of Frege:

> When one says 'x is identical with y' this, I hold, is an incomplete expression. It is short for 'x is the same A as y,' where 'A' represents some count noun understood from the context of utterance – or else it is just a vague expression of a half-formed thought. Frege emphasized that 'x is *one*' is an incomplete way of saying 'x is one A, a single A' or else has no clear sense: since the connection of the concepts *one* and identity comes out just as much in the German 'ein und dasselbe' as in the English 'one and the same,' it has always surprised me that Frege did not similarly maintain the parallel doctrine of relativized identity, which I have just briefly stated. (1967, p. 3)

Geach often associates his thesis that identity is relative with the notion of a *criterion of identity*: "I maintain that it makes no sense to judge whether x and y are 'the same' or

whether x remains 'the same' unless we add or understand some general term 'same F.' That in accordance with which we thus judge as to the identity, I call a *criterion* of identity." And he takes his view to have the implication that "x is the same A as y" does not "split up" into "x is an A (and y is an A) and x is the same as … y" (1962, pp. 39, 152). (On criteria of identity, see further Chapter 39, OBJECTS AND CRITERIA OF IDENTITY.)

He also remarks (1980, p. 181), "On my own view of identity I could not object in principle to different As being one and the same B."

This last quotation gives us a way of understanding Geach. Say that an equivalence relation R is *absolute* if and only if, if x stands in it to y, there cannot be some other equivalence relation S, holding between anything and either x or y, but not holding between x and y. If an equivalence relation is not absolute it is *relative*. Now the question can be raised whether there are any *absolute* equivalence relations.

Geach's claim is that there are not. This is vaguely stated, however. Given the definition of an absolute equivalence relation above, classical identity must be an absolute equivalence relation if it exists, as must any necessarily uninstantiated equivalence relation. So, stated more precisely, Geach's claim is that *any expression for an absolute equivalence relation has the null class as its extension*. This entails that *there can be no expression for classical identity*, given that we understood it as the relation everything stands in to itself and nothing else. This is what Geach argues against Quine. We shall look at his argument later.

The Sortal Relativity of Identity

It may be that whenever 'A' is interpretable as a count noun or sortal term in a language L, the expression (interpretable as) 'x is the same A as y' in language L will be satisfied by a pair of things only if the *I-predicate* of L is satisfied by the pair. So no truth of the form 'x and y are the same A but different Bs' will be expressible in the language. Geach's contention that this is a possibility is thus an additional thesis – the *thesis of the sortal relativity of identity* – which is not entailed by his thesis of the non-existence of absolute identity, and in fact, and far more importantly, does not entail the latter, and so cannot just be rejected along with it. This thesis is the central point at issue between Geach and Wiggins. It entails that a relation expressible in the form 'x is the same A as y' in a language L need not entail indiscernibility even by the resources of L. Geach argues for it by illustrative examples – the cases of the cat on the mat (1980, p. 215), Heraclitus and the bath water (1962, pp. 150–151), and men and heralds (1980, pp. 174 ff.). We shall look at these later. In each case Geach argues that the relevant relation does not express indiscernibility even by the resources of our language.

The Derelativization Thesis

The sortal relativity thesis depends for its significance on the distinction between sortal (or what Geach calls 'substantival') terms and non-sortal (or 'adjectival') terms. For we can simply introduce *by abbreviative definition* an expression of the form 'x is the same A as y' to denote a relative equivalence relation R and, again by abbreviative definition, an expression of the form 'x is an A' to denote the property of being R to something or other, and then it may turn out that in the language thus expanded some statement of the form 'x is an A,

y is an A, x is the same A as y but x and y are different Bs' is true. This is how Geach does introduce the concept of a surman, defining 'x is the same surman as y' to mean 'x and y are men with the same surname' and then 'x is a surman' to mean the same as 'x is the same surman as something or other.' But his opponents will simply deny that 'surman,' so introduced, functions as a sortal term, that is, conveys a genuine criterion of identity. (See Chapter 39, OBJECTS AND CRITERIA OF IDENTITY.)

Geach's response to this line of objection is to offer his own account of the distinction between sortal terms and non-sortal terms – an account which is consistent with the thesis of the sortal relativity of identity.

The basic distinction is between those terms 'A' such that 'same A' makes sense, and those terms of which this is not true. In his (1962) and (1967) Geach, following Aquinas, calls this the distinction between 'substantival' and 'adjectival' terms. He illustrates it by reference to Frege's remarks about the number of red things:

> Frege said that only such concepts as "sharply delimited" what they applied to, so that it was not "arbitrarily divisible," could serve as units for counting … Frege cagily remarks that in other cases, e.g., "red things," no finite number was determined. But, of course, the trouble about counting the red things in a room is not that you cannot make an end of counting them, but that you cannot make a beginning, you never know whether you have counted one already, because "the same red thing" supplies no criterion of identity. (1962, p. 63)

Thus, according to Geach, 'red thing' is an adjectival term because 'same red thing' provides no criterion of identity and makes no sense, whereas 'apple,' say, and, as he goes on to mention, 'gold,' are substantival terms because 'same apple' and 'same gold' do provide criteria of identity (the difference between the latter two terms is the difference between *count nouns* and *mass terms*, see Chapter 39, OBJECTS AND CRITERIA OF IDENTITY).

But why does 'same red thing' not make sense, whereas 'same apple' does? And what is the relation in the latter case between the two-place predicate 'is the same apple as,' and the one-place predicate 'is an apple'?

Geach's proposes that the latter is derived from the former by what Quine has called *derelativization*. Quine writes: "commonly the key word of a relative term is also used *derelativized*, as an absolute term to this effect: it is true of anything x if and only if the relative term is true of x with respect to at least one thing. Thus anyone is a brother if and only if there is someone of whom he is a brother" (1960, p. 106). It would be nonsense to suppose that the explanation could go the other way round; that we could start with 'is a brother' and then go on to explain 'is a brother of.' Just so, Geach claims, with respect to 'is an apple' and 'same apple.' 'Is an apple' is definable by derelativization as 'is the same apple as something,' and 'the same' in 'the same apple as' is not a syntactically separable part but an index showing we have here a term for a relation with certain logical properties, like the 'of' in 'is a brother of' (1973, p. 291).

'A' is a substantival term, then, according to Geach, if 'is (an) A' is to be explained as formed by derelativization from 'is the same A as.' For, since 'the same' is merely an index of a certain type of relation, we cannot start with the monadic predicate 'is (an) A' and then explain the relational predicate 'is the same A as' in terms of it.

So, Geach claims, how he introduces talk of surmen is not a mere trick, but a faithful representation of the way in which substantival terms generally are introduced.

Of course, Geach need not hold that every equivalence relation can serve in this way to introduce a substantival term; in fact, in his later writing on identity (1991, pp. 294 ff.) he

denies this and disowns the 'surman' example. But his position is that every substantival term is derelativized from an expression for an equivalence relation and that merely *relative* equivalence relations may serve in this role.

To refute Geach, then, what his opponents must do is to point to features of the semantics of substantival terms which are incompatible with their being derelativized from expressions for relative equivalence relations, whilst to establish his thesis Geach must demonstrate that there are no such features.

It is in the light of this that Geach's views on *counting* must be understood.

The Counting Thesis

To count we distinguish items not yet counted from those already counted, and identify ones already counted as being among those already counted. Many philosophers think that if x is an A and y is an A and x and y are not (classically) identical then x and y cannot be counted as *one* A. Accordingly, when counting As one must count them as one only if they are identical. But, in fact, as Geach points out, it is perfectly possible to count by a relation weaker than classical identity – a relative equivalence relation. Suppose R is a relation weaker than identity which holds among As and which sorts the As into equivalence classes, then one can count As according to the rule that As x and y are to be counted as one just in case x bears R to y. To do so one assigns *one* to any A and to any A which bears R to that A, and to no other A; *two* to any A to which a number has not yet been assigned, to any A which bears R to it and to no other A, and so on. The final number reached will be the count of As when counting by R, and it may be smaller than the number arrived at when counting by classical identity.

It is, of course, a further question whether we ever do count by a relative equivalence relation, as Geach claims. But the correctness of Geach's counting thesis – the thesis that we *can* do so without falling into confusion or inconsistency – is enough to show that the mere fact that a noun is a count noun does not suffice to show that it *cannot* be understood as a derelativization of an expression for a relative equivalence relation. Moreover, given this analysis of counting, Geach can demand his opponents explain how, on their view, any term can be (logically) adjectival. For if the relation we count by is always identity then it is at first sight hard to see why the distinction between substantival and adjectival terms does not simply collapse; that is, it is hard to see how 'same A' can make any better sense in some cases (e.g., 'same man') than in others (e.g., 'same red thing'), for in every case 'x is the same A as y' means 'x is an A and y is an A and x and y are identical.'

The Irreducibility of Restricted Quantification

An important component of Geach's position is his thesis that for any sortal term 'A' there is a distinction between restricted quantification over As and unrestricted quantification over things that *are* As.

'Some man is F,' Geach holds, is not equivalent to 'something is a man and is F,' and 'every man is F' is not equivalent to 'everything, if it is a man, is F.' Again, he says, if 'A' and 'B' are two sortal terms, 'Every (some) A is F' need not be equivalent to 'Every (some) B is F,' even

if 'Every A is a B' and 'Every B is an A' are both true. Thus, for example, he claims, 'Every (some) man is F' need not be equivalent to 'Every (some) herald is F' even if every man is a herald and every herald is a man.

These claims about restricted quantification are, in fact, consequences of Geach's thesis of the sortal relativity of identity. We can see this by looking at two of the examples he uses to argue for the sortal relativity thesis.

First, the case of the cat on the mat. If Tibbles is on the mat and is the only cat there, there will, nonetheless, Geach claims, be many numerically distinct individuals on the mat which are cats and the same cat as Tibbles. For each proper part of Tibbles which is smaller than Tibbles by just one hair is a cat and (since there is only *one* cat on the mat) the same cat as Tibbles and every other such part. If so 'Some cat is F' is not equivalent to 'something is a cat and is F.' For, in this situation, 'some cat is F' is true just in case 'the cat on the mat is F' is true. But 'the cat on the mat lacks hair number one' (the first hair considered) is not true, so 'some cat lacks hair number one' is not true, but 'something is a cat and lacks hair number one' is.

Second, the case of Heraclitus and the river. If Heraclitus bathes twice in the river and, as Geach claims, the river is at any moment a collection of water molecules and so is the same water as the collection of water molecules then in the river bed (since there are not two collections of water molecules occupying exactly that space at that time), then it will be true that Heraclitus bathes in *something which is water* on two successive occasions, but it will be false (since new waters are ever flowing in) that there is *some water* that Heraclitus bathes in twice.

If Geach is right that identity is sortal relative, then, the irreducibility of restricted quantification follows. But one can accept the latter thesis without accepting the former.

The 'Name for an A'/'Name of an A' Distinction

The distinction between restricted and unrestricted quantification, if accepted, carries with it a distinction between two senses in which a name may name an A: a name may name *something which is an A*; more strongly, it may name *some A*. In the former case Geach calls it a name *of* an A; in the latter case a name *for* an A. Thus any non-empty name *for* an A is also a name *of* an A, but, if restricted quantification is irreducible, a name *of* an A need not be a name *for* an A. In the Tibbles case, for example, 'Tibbles' is both a name *for* a cat and a name *of* a cat, but if 'c' names a proper part of Tibbles which is a cat, it will be a name *of* a cat, but not a name *for* a cat.

With this distinction made Geach is able to explain the truth-conditions of statements containing restricted quantification and their relation to the truth-conditions of statements containing unrestricted quantification as follows:

'F (some A)' is true iff 'F(a)' is true for some interpretation of 'a' as a name *of* and *for* an A;
'F (any A)' is true iff 'F(a)' is true for any interpretation of 'a' as a name *of* and *for* an A.

If we delete from the above truth-conditions for 'F(some A)' and 'F(any A)' the restriction to proper names *of* and *for* an A we obtain truth-conditions for 'For some x, Fx' and 'For any x, Fx,' respectively. It is worth noting that Geach does *not* intend that these explanations should be read as employing substitutional quantification (1978).

Thus, we can say, a name 'a' which names something which is an A is a name *for* an 'A' if 'F(a)' is a sufficient condition for the truth of 'F(some A)' otherwise it is merely a name *of* an A.

(A complication to be mentioned here is that Geach holds that there is no absolute distinction between general and proper names, since a name may be at the same time a name of several As and a name of just one B. Consequently, Geach would say, in the Tibbles case 'Tibbles' is a proper name *for* and *of* a cat, but is also a general name *of* each proper part of Tibbles which qualifies as a cat. This position does not appear to be logically required by his other views. If 'Tibbles' names Tibbles, and Tibbles is the same cat as c (a proper part of Tibbles which qualifies as a cat), why must we infer that 'Tibbles' names c unless *same cat* is an absolute equivalence relation? But, by hypothesis, it is not. In the sequel, therefore, I will concentrate on Geach's views about identity and leave aside his views on general and proper names.)

This account of the name *for* an A/name *of* an A distinction takes for granted the distinction between restricted and unrestricted quantification. However, Geach thinks that the former distinction can be explained independently and thus can be used to cast light on the latter. A name *for* an A, Geach suggests, can be explained as a name associated with the criterion of identity: *same A*. A name of an A which is not a name *for* an A, on the other hand, is a name which names something which is an A but is not associated with that criterion of identity.

The idea of a criterion of identity is a much-stressed element of Geach's conceptual repertoire, which he derives from Frege and Wittgenstein, but it is an idea which he shares with many philosophers, including strong opponents of his views on relative identity. It is a standard, though not uncontroversial view, that reference is only possible against the background of a criterion of identity, and hence that any proper name must have a sense (not necessarily an individuating sense of the sort attacked by Kripke, 1980) which has a criterion of identity as a component (see Chapter 39, OBJECTS AND CRITERIA OF IDENTITY).

The general idea can be understood as follows. To assign a name a use is to determine its contribution to the truth-conditions of the sentences in which it occurs. To contend that to introduce a name one must associate it with a criterion of identity is, then, to say that one must do this to fix its contribution to the truth-conditions of sentences in which it occurs.

To consider why this is thought to be the case would take us too far afield. But for now it suffices to note that what is disputable about Geach's position is not the importance he gives to criteria of identity but his claim that a name *of* an A – a name which names something which is an A – can *fail* to be a name *for* an A and that something can be an A without satisfying the criterion of identity for As.

I now turn to an examination of the main arguments for and against Geach's claims.

Geach versus Quine: A Baroque Meinongian Ontology

Geach argues for his thesis (1), that absolute identity does not exist, by trying to show that absurdities result from Quine's claim that one can always reinterpret the range of the quantifiers in a language L so as to ensure that the I-predicate of L expresses absolute identity, and not merely indistinguishability by the stock of predicates contained in L. To be relevant to its target the argument must be read as assuming that *if* absolute identity is expressible in language at all *then* one can always reinterpret the range of the quantifiers in any language

L in such a way as to ensure that the I-predicate of L expresses absolute identity; but this assumption seems unexceptionable. Geach argues that this Quinean claim leads to a 'baroque Meinongian ontology.' There are, however, two versions of Geach's argument, an earlier one and a later one, and these need to be considered separately, since the earlier argument is vulnerable to a criticism which does not apply to the later one.

In its earlier version the argument goes as follows. Suppose we have a language L containing expressions for equivalence relations E_1, E_2, E_3 and a theory T expressible in L in which these expressions are employed. Then, for each such expression E_n we can consider that sub-language of L (L_n) in which that expression is an I-predicate, and that fragment of T (T_n) expressible in that sub-language. Adopting Quine's suggestion, we can then reconstrue the range of the quantifiers in each L_n and reinterpret the predicates of L_n so that while each true sentence of T which is also a sentence of T_n remains true in T_n, E_n in L_n no longer expresses a relation which holds between distinct items, but rather the relation of absolute identity. The range of the quantifiers in each L_n will now be different from their range in any other L_n, and also different from their range in L. For instance, if we start off with a language in which we quantify over token words, and in which the predicates 'is the same token word as,' 'is equiform to,' and 'has the same dictionary entry as' all occur, we may consider fragments of this language, and correspondingly fragments of theories expressible in this language, in which these various predicates qualify as I-predicates.

Following Quine's suggestion we may then reconstrue the quantifiers and reinterpret the predicates in these various language-fragments in a way that ensures, for example, that 'has the same dictionary entry as' expresses absolute identity in the language-fragment in which it is the I-predicate. One way of doing this is to regard the quantifiers in this language-fragment as ranging over classes of words which have the same dictionary entry. Similarly, one may regard the quantifiers in the language-fragment in which 'is equiform to' is the I-predicate as ranging over classes of equiform words. Since equiform words need not have the same dictionary entry, nor words with the same dictionary entry be equiform, the ranges of the quantifiers in these two language-fragments will now be different, and different again from the range of the quantifiers in the original language, in which neither 'has the same dictionary entry as' nor 'is equiform to' is an I-predicate.

Now Geach does not claim, in the earlier version of his argument, that interpreting quantifiers in this way, so as to get at a relation of absolute identity, involves one in logical incoherences or absurdities, merely that it sins against a highly intuitive methodological program enunciated by Quine himself, namely that "as our knowledge expands we should unhesitatingly expand our ideology, our stock of predicables, but should be much more wary about altering our ontology, the interpretation of our bound name variables" (Geach, 1972, p. 243), and that it has a consequence possibly unwelcome to a lover of desert landscapes, namely that

> since a rich language L may allow for our carving many sub-languages, L_1, L_2, L_3 … out of it, users of L are committed to the existence, not only of a realm of objects for which the I-predicable of L itself gives the criterion of absolute identity, but also for each of these possible sub-languages L_n, of a distinct realm of objects for which the I-predicable of L_n gives the criterion of absolute identity. (1972, p. 248)

Geach's argument is thus that in view of the mere *possibility* of carving L_1, L_2, L_3 … out of L, if the thesis maintained by Quine is right, users of L will be ontologically committed to

any number of entities which are not spoken of, or quantified over, in L. They will be so committed because any sentence of L which is also a sentence of some sub-language L_n will have just the same truth-conditions in L and L_n and hence also in any theory T expressible in L and any theory got from T by mere omission of the sentences of L which are not sentences of L_n, but "[it] is, of course, flatly inconsistent to say that as a member of a larger theory a sentence retains its truth-conditions but not its ontological commitment" (Geach, 1973, p. 299).

The crucial premise of this argument, it therefore emerges, is that sameness of truth-conditions entails sameness of ontological commitment. But, however it may be with other notions of ontological commitment, this is not true of Quine's. For Quine, the ontological commitments of a theory are those entities which must *lie within the domain of quantification* of the theory if the theory is to be true; or, alternatively expressed, those entities the predicates of the theory have to be true of if the theory is to be true. A theory is not, if I may so express it, ontologically committed to what is required to be in *the universe* if it is to be true, but merely to what it is required to be in *its universe* if it is to be true. Because this is so there is no argument from sameness of truth-conditions to sameness of ontological commitments.

Thus, as an *ad hominem* argument against Quine (which is how he himself describes it) Geach's argument, in the earlier version now being discussed, has to be judged a failure.

Matters stand differently with the later version of the argument, though it, too, in the end turns out not to be cogent (the criticism following is indebted to Dummett, 1991). The difference between the earlier and later version is that in the later (to be found in Geach, 1973) Geach's claim is not merely that Quine's thesis about the interpretation of quantification has a consequence which is unpalatable and "possibly unwelcome to a lover of desert landscapes," but that it leads to an out-and-out logical absurdity, the existence of *absolute* surmen. Because Geach is now making this stronger claim, the objection that his argument depends upon the incorrect assumption that sameness of truth-conditions entails sameness of ontological commitments is no longer relevant. In order to make out his case Geach has to establish just two points. First, that there are sentences of English (supplemented by the predicate 'is the same surman as') which are evidently true and which, considered as sentences of that fragment of English in which 'is the same surman as' is an I-predicate, when this is interpreted in the way Quine suggests, can be true only if absolute surmen exist. And second, that the existence of absolute surmen (entities for which 'is the same surman as' expresses absolute identity) is absurd.

But in the end Geach fails to establish these points. Quine would say that, for the fragment of English in question, the domain of the variables can be considered as consisting of classes of men with the same surname and the predicates interpreted as holding of such classes. Thus, the predicate 'is the same surman as' will no longer be true of *men* if we adopt Quine's suggestion (I am writing, remember, in English, not in the fragment of English under discussion), but rather of classes of men with the same surname – these, then, will be the entities which are Geach's 'absolute surmen.' Now, Geach attempts to rule out such a suggestion by the argument that 'Whatever is a surman is by definition a man.' But this argument fails. The predicate 'is a man' will also be in the language-fragment in which 'is the same surman as' is the I-predicate; and so it, too, will be reinterpreted, if we follow Quine's suggestion, as holding of classes of men with the same surname. Thus the sentence 'Whatever is a surman is a man' will be true in the language-fragment interpreted in Quine's way, just as it is in English as a whole. What will *not* be true, however, is that whatever the

predicate 'is a surman' is true of, *as it occurs in the language-fragment reinterpreted in Quine's way*, is a thing of which 'is a man,' *as it occurs in English as a whole*, is true of. But Geach has no right to demand that this should be the case. Even so, this demand can in fact be met. For the domain of the interpretation of the language-fragment in which 'is the same surman as' in the I-predicate can be taken to consist of men, namely to be a class containing exactly one representative man for each class of men with the same surname. Thus, as Geach says, "absolute surmen will be just some among men" (1973, p. 300). Geach goes on, "There will, for example, be just one surman with the surname 'Jones'; but if this is an absolute surman, and he is a certain man, then which of the Jones boys is he?" But this question, which is, of course, only answerable using predicates which belong to the part of English not included in the language-fragment in which 'is the same surman as' is the I-predicate, is not an impossible one to answer. It is merely that the answer will depend upon the particular interpretation which the language-fragment has been given. Geach is, therefore, not entitled to go on "Surely we have run into absurdity." It thus seems that his argument for the non-existence of absolute identity fails.

Cats, Rivers, and Heralds

Geach's thesis (2) – his sortal relativity thesis – is, however, another matter. For it is neither entailed by, nor entails, the thesis of the non-existence of absolute identity. Geach argues for it by appeal to well-known examples: the case of the cat on the mat, Heraclitus and the river, and the men and heralds case. I shall concentrate on the case of the cat on the mat.

There are two versions of the argument about the cat on the mat. One version goes like this (see Wiggins, 1968). Suppose Tibbles, is on the mat. Now consider that portion of Tibbles which includes everything except the tail, call it 'Tib.' Since Tibbles and Tib are different sizes they are non-identical. But if we amputate the tail they now occupy exactly the same space. If Tibbles is still a cat, it is hard to see why Tib is not, even if it was not before. Yet they are distinct individuals, because their histories are different. But there is just *one* cat present. So they cannot be distinct *cats*. They must be the same cat, even though distinct individuals; and so being one and the same cat must be a relative identity relation, that is, a relation which does not ensure the indiscernibility of its terms.

A second version (Geach, 1980) goes as follows. Tibbles is sitting on the mat and is the only cat sitting on the mat. But Tibbles has at least 1,001 hairs. Geach continues:

> Now let c be the largest continuous mass of feline tissue on the mat. Then for any of our 1,000 hairs, say h_n, there is a proper part c_n of c which contains precisely all of c except that hair h_n: and every such part c_n differs in a describable way both from any other such part say c_m, and from c as a whole. Moreover, fuzzy as the concept *cat* may be, it is clear that not only is c a cat, but also any part c_n is a cat: c_n would clearly be a cat were the hair h_n to be plucked out, and we cannot reasonably suppose that plucking out a hair *generates* a cat, so c_n must already have been a cat. (1980, pp. 215–216)

The conclusion, of course, is the same as before: all the distinct entities must qualify as cats since there is only one cat on the mat and *same cat* must be a merely relative identity relation.

The second version is vulnerable to an objection – that the concept of *cat* satisfies a maximality requirement: that nothing can be *both* a proper part of a cat *and* a cat – which

does not apply to the first. But obviously neither version will convince an opponent, who will simply deny that Tib or any of the entities distinct from Tibbles in the situation is ever predicatively a cat, pointing to the modal and historical properties possessed by Tibbles not possessed by the other entities in support.

However, a defender of Geach's position will want to know the relevance of the differences. They prove that Tib and the like are numerically distinct from Tibbles, but we knew that all along. The debate is about whether they are cats. Are they not too cat-like not to be? How can things so similar to a paradigm cat not be cats? And in response to the denial that Tib is a cat after the operation in the version of the argument given by Wiggins, the relative identity theorist can ask why it should not be a cat afterwards, even granted that it is not before. Granted it has an unfeline past, why does that exclude its having a feline present (and future)? Unless it is simply stipulated that however cat-like something is at a time it cannot qualify as a cat unless it has the right sort of past (and future?).

In fact it is clear that there are three possible lines of solution to the puzzle of the cat on the mat:

1. Geach is wrong. The correct definition of 'cat' applies only to Tibbles itself and not to Tib and its like. However, it is correct to say that Tib is a cat, after the amputation, if not before, since 'is' has, as well as its predicative sense, various constitutive senses (Wiggins, 1968; Shoemaker, 1970; Lowe, 1989) and since Tib shares all its matter with Tibbles after the amputation it 'is,' then, in one legitimate sense, a cat.
2. Geach is right that many distinct individuals are present each of which is predicatively a cat. Counting is not always by identity. In counting cats we count by a weaker equivalence relation. Consequently, we speak correctly in saying that there is just one cat present, even though many distinct individuals are present each of which is predicatively a cat. But in counting cats the relation we count must be the one we express by 'is the same cat as.' This, then, must be the relevant relation. Thus 'is the same cat as' is an expression for a relative equivalence relation.
3. Geach is right that many distinct individuals are present, each of which is predicatively a cat, but counting is by identity. When counting cats, not everything that qualifies as a cat counts. 'There is just one cat on the mat' means 'some cat is on the mat and every cat which is on the mat is identical with that one.' The only entities to be counted when counting cats are those which fall within the range of the natural-language quantifying expressions, 'some cat' and 'every cat.' But it is only if 'some cat is F' is equivalent to 'something is a cat and is F' and 'every cat is F' is equivalent to 'everything, if it is a cat, is F' that these quantifying expressions must be taken to range over everything which qualifies as a cat. These equivalences do not hold. Of the 1,001 items in the situation which qualify as predicatively cats, only one – Tibbles – falls within the range of 'some cat' and 'every cat.'

It seems that the linguistic facts are consistent with each of these solutions, so the puzzle cannot count *decisively* either for or against Geach's view. But the availability of the third line of solution also makes it evident that no example of this type could even provide a *reason* for embracing the sortal relativity thesis, since the distinction between restricted and unrestricted qualification which is all that the type (3) solution relies upon is something to which a proponent of a Geachian type (2) solution is already committed. On grounds of economy, then, it seems that type (3) solutions to problems of the sort Geach describes are always preferable to type (2) solutions.

The availability of the type (3) solution also puts the position of the proponent of the type (1) solution in a clearer light. It makes it clear that opposing the concept of relative identity, by itself, provides no motive for insisting on the type (1) solution or for endorsing the 'is' of constitution. Such a motive requires an argument for rejecting the thesis of the irreducibility of restricted (sortal) qualification to unrestricted quantification, but it is hard to see what form such an argument might take. Since both sides agree that it is correct to say of something numerically distinct from Tibbles in the situation that it 'is' a cat but disagree over the meaning of 'is,' it appears that the crucial point at issue between the proponent of the type (1) solution and the proponent of the type (3) solution is whether '*is a cat*,' *understood as a syntactically simple predicate in which the 'is' is merely the 'is' of predication – a mere fragment of a predicate which expresses no property or relation by itself – applies univocally both to Tibbles and to (at least one of) the entities present in the situation described which are distinct from Tibbles*. But how this issue might be decided is wholly unclear.

However, there is a third variant of the puzzle which brings new considerations into play. This is Lewis's version (Lewis, 1993).

Lewis presents the puzzle as one about vagueness. He then offers two solutions, in accordance with his own preferred account of vagueness as always having its source in "semantic indecision," the view that the reason why 'the Outback' is vague is that no one has been fool enough to decide where it should be deemed to lie. There is not something out there in the world with imprecise boundaries. The only intelligible account of vagueness locates it in our thought and language (Lewis, 1986, p. 213).

The first of his solutions rest on a supervaluational semantics according to which what is definitely true is what remains true under all precisifications. It accounts for our confidence that there is just one cat on the mat consistently with the thesis that counting is always by identity. According to this solution there is no one thing on the mat which is clearly a cat, though it is clear that there is a cat and exactly one on the mat.

Lewis's second solution does not appeal to supervaluationism to deliver the verdict that there is just one cat on the mat. According to this solution there are many, numerically distinct, entities on the mat which are clearly cats, just as Geach says, but 'there is just one cat on the mat' is nonetheless true since all of these massively overlap – they are almost identical – and our statement 'there is just one cat on the mat' records the result of counting not by identity but by almost-identity. This solution does not require Geach's rejection of absolute identity, and so Lewis does not think of it as a relative identity solution. But it entails that where there is just one cat there may be many numerically distinct individuals, each of which is a cat, and counting is not always by identity, which is what Geach wishes to establish with the tale of the cat on the mat.

Here is Lewis's statement of the puzzle:

> Cat Tibbles is alone on the mat. Tibbles has hairs h_1, h_2, …, h_{1000}. Let c be all of Tibbles, and c_1 all of Tibbles except for h_1 and similarly for c_2, …, c_{1000}. Each of these is a cat. … Why? … [S]uppose it is spring, and Tibbles is shedding. When a cat sheds the hairs do not come popping off, they become gradually looser. By the end … the loose hairs are no longer parts of the cat. Sometime before the end, they are questionable parts…. Suppose each of h_1, h_2, …, h_{1000} is at this questionable stage. Now indeed all of c_1, c_2, …, c_{1000} and also c have equal claim to be a cat. (Lewis, 1993, p. 166)

Lewis's first solution appeals directly to the idea of vagueness as semantic indecision concerning the extension of 'cat.' Our concept of a cat is vague because we have not made the

term precise. But consistently with what has been established it means we can decide to make it entirely precise in any of a number of ways. Subsequent to each such decision, each such precisification, it will turn out that there is just one cat on the mat – the cat-candidates will be reduced to one. But each precisification will identify a different candidate as the cat on the mat. Comparably, 'orange' is vague. We have not decided the precise boundary between orange and yellow or orange and red. We can make it precise in numerous ways consistently with the clear truths about orange, for example, that whatever is orange is not red and that whatever is orange is colored. On each of these precisifications there will be a line which is the boundary between orange and red, but different precisifications will identify different lines as the boundary.

The difficulty with this first, 'one cat,' solution, this solution by disqualification, as Lewis calls it, is that it cannot be that on each precisification just one cat-candidate turns out to be a cat. Precisifying decisions must preserve clear truth. So one cannot decide to precisify 'cat' in such a way that c_{59} is a cat and c_{60} is not if the only difference between these is that one is on my left as I face the mat and the other not, or one is closer to an edge of the mat than the other, or one is slightly browner than the other. It is clearly true that such differences cannot make a difference in respect of cathood so a precisification is not eligible that makes them do so. Since amongst c and $c_1, \ldots, c_{1000}$ there will be pairs so related that there is no difference between them that could make a difference in respect of cathood, given the already established meaning of 'cat,' no decision could be made, consistently with the meaning 'cat' actually has, which determines that exactly one of the many cat-candidates falls within the (new) extension of 'cat.'

So, given the Lewisean assumption that semantic indecision is the source of all vagueness, we cannot say, consistently with holding it to be clearly true that there is one cat on the mat, that the cat-candidates are equally good, because they are all equally indeterminate examples of cathood.

Rather, we must say that they are all equal because they are all clearly cats. This is Lewis's second proposal. But, how, then, can there be just one cat on the mat?

Lewis's answer is that any two cat-candidates are almost completely identical, they massively overlap. And it is this relation we count by in counting cats (in almost every conversational context). So in almost every conversational context it is correct to say that there is just one cat on the mat.

But how then are we to understand the description '*the* cat on the mat'? We want it to be clearly true that the cat on the mat is hairy, but not clearly true that the cat on the mat includes hair number 17. Suppose we subject the description to Russellian translation. We then get as translations of 'the cat on the mat includes h_{17} (is hairy)':

> There is something that is identical to everything which is a cat on the mat and nothing else, and that includes h_{17} (is hairy)
> There is something that is identical to everything which is a cat on the mat and nothing else, and everything which is a cat on the mat includes h_{17} (is hairy)
> But these are all false, because nothing is identical to everything which is a cat on the mat.

But we can relax the translations by replacing 'identical' with 'almost identical.' Then both the translations' parts are no longer equivalent.

> There is something that is almost-identical to everything which is a cat on the mat and nothing else, and that includes h_{17}

is true.

> There is something that is almost-identical to everything which is a cat on the mat and nothing else, and everything which is a cat on the mat includes h_{17}

is false.

But both:

> There is something that is almost-identical to everything which is a cat on the mat and nothing else, and that is hairy

and:

> There is something that is almost-identical to everything which is a cat on the mat and nothing else, and everything which is a cat on the mat is hairy

are true.

So if 'the cat on the mat is F' is interpreted as receiving the truth-value given by the two relaxed Russellian translations if there is one, and as indeterminate otherwise, we get what we want, that 'the cat on the mat is hairy' is clearly true, and 'the cat on the mat includes hair 17' is not.

We also want 'Tibbles is hairy' to be clearly true and 'Tibbles includes hair 17' not to be, and, of course, we want 'Tibbles is the cat on the mat' to be clearly true. But this is secured immediately if the reference of 'Tibbles' is fixed via the description 'the cat on the mat,' which must at least imply that the truth of the identity is stipulated. Thus we get the Geachian distinction between names like 'Tibbles,' which are names for cats because their reference is stipulated by reference-fixing descriptions of the type 'the cat …' which are to be understood via relaxed Russellian translations, and names like 'c_{17},' which are merely names of cats.

This distinction also brings with it Geach's distinction between restricted (sortal) quantification and unrestricted quantification. In this context 'some cat is F' should be true if and only if 'the cat on the mat is F' is true, if and only if 'Tibbles is F' is true. So 'Some cat includes hair number 17' should not be true, though 'something is a cat and includes hair number 17' is true. Hence, in general, 'some cat is F' should be true iff 'a is F' is true for some interpretation of 'a' as a name of and for a cat.

So the verdict on Geach's thesis of sortal relativity must be tentative. It is not proven; but there seems to be no argument weighing conclusively against it. There seems no evident way to resolve the disputes over Geach's versions of the puzzle about the cat on the mat, whilst the Lewisean version, even if the considerations just gone through are accepted, provides support for it only given the substantial assumption that all vagueness must be identified with semantic indecision.

Substantival Terms and the Derelativization Thesis

This is not the case, however, with Geach's derelativization thesis: that every substantival term is to be explained as the derelativization of an expression for an equivalence relation. In this case it seems clear that Geach's contention is overambitious, as Dummett (see 1981; 1991) demonstrates.

The first counter-examples to the derelativization thesis Dummett notes are *derivative* count nouns, where a count noun 'A' is a derivative count noun when there is some count noun 'B' such that 'is the same A as' may be satisfactorily explained as 'is an A and is the same B as.'

As Dummett points out, ironically enough Geach himself draws attention to counter-examples of this class when he introduces the derelativization thesis. If Geach is right that 'is a brother' is derived from 'is a brother of,' it cannot also be understood as derived from 'is the same brother as.' Rather, we have to understand the latter as derived from 'is a brother' (or else, implausibly, reject it as meaningless); and the evident explanation is that 'is the same brother as' means 'is a brother and is the same man as.'

As Dummett argues, such nouns as 'postman' and 'baker' also seem to be exceptions. We understand 'is the same postman as' as meaning 'is a mail deliverer and is the same man as.' We do not have to learn 'is the same postman as' before we understand 'is a postman' and we cannot be thought of as required to derive the latter from the former by derelativization.

As Dummett notes, abstract nouns are also counter-examples to the derelativization thesis.

Consider the noun 'shape.' This is certainly a count noun, but it seems clear that Geach's derelativization thesis does not give its semantics. There is a competing account which is far more plausible, namely the account sketched out by Frege in the *Grundlagen*, using the concept of direction as his model. According to this account, the noun 'shape' may be thought of as introduced into the language as follows: we begin by introducing an expression 'has the same shape as' for an equivalence relation between material objects; we then introduce the functional expression 'the shape of,' explained in such a way as to yield the equivalence of 'the shape of x is the same as the shape of y' and 'x has the same shape as y'; and finally we explain 'x is a shape' to mean 'for some y, x is the shape of y.' We can supplement this account by stipulating that 'x is the same shape as y' is to mean 'x is a shape and x is the same as y,' which is equivalent to 'for some z, for some u, x is the shape of z and y is the shape of u, and z has the same shape as u.' This account seems superior to Geach's because it reflects the necessary order of language acquisition. There *could not* be a language in which it was possible to make reference to shapes but which did not contain a functional expression with the sense of 'the shape of.' This is because shapes, unlike, say, colors, are not possible objects of ostension: even against the background of an appropriate criterion of identity one cannot pick out a shape by pointing and saying 'this.' The only way to refer to a shape is as the shape of some already-identified object or region. Thus, a language could not contain the predicates 'is a shape' and 'is the same shape as' unless it also contained the functional expression 'the shape of,' and the Fregean account is in accord with this fact.

Another example for which the Fregean account seems plausible is 'nationality.' Here, too, it seems that we understand 'x is a nationality' and 'x is the same nationality as y,' respectively, to mean 'for some x, x is the nationality of y' and 'for some z, for some u, x is the nationality of z and y is the nationality of u and z has the same nationality as u,' understanding 'the nationality of' in such a way as ensures the equivalence of 'the nationality of x is the same as the nationality of y' and 'x has the same nationality as y,' that is, 'x is a citizen of the same country as y.' But the reason seems slightly different from the reason in the previous case. For, while shapes are not possible objects of ostension, nationalities are. If I point towards a man and say 'this nationality,' there may well be no choice, given the criterion of identity invoked, of objects to which I can be referring. But if I point and say 'this shape' there will always be more than one (if there is even one) possible object of reference compatible with the criterion of identity I have invoked. Nevertheless, it does seem that a language could not

contain any means of making reference to nationalities, and hence could not contain the predicates 'is a nationality' and 'is the same nationality as,' unless it also contained a functional expression with the sense of 'the nationality of.' This is because no one could understand the notion of 'a nationality' without being aware of those relations among human beings in which there being such things as nationalities consists: and he could not be aware of these without being able to refer to individual human beings and their nationalities.

Once we recognize, with Dummett, that abstract nouns are counter-examples to Geach's derelativization thesis, it becomes plausible that mass terms are also.

Consider the mass noun 'gold.' Like shape, and unlike colors or nationalities, parcels of gold are not possible objects of ostension. Pointing and saying 'this gold' does not determine which object I am referring to. This is because any proper part of a parcel of gold is itself a parcel of gold, but a distinct parcel from that of which it is a proper part. Thus, just as in order to identify shapes we must relate them to some other, already-identified objects or regions, as the shapes *of* those objects or regions, so, to identify a parcel of gold, one must relate it to some already identified object as the gold *of* that object; just as one may identify a shape as the *shape* of so-and-so's wedding ring, so one may identify a parcel of gold as the *gold* of her wedding ring; and, as the possibility of reference to shapes depends upon the existence of such means of identification, the same holds of the possibility of reference to parcels of gold. And so a language *could not* contain the means of making reference to parcels of gold, and hence could not contain the predicates 'is gold' and 'is the same gold as' (understood as applicable to parcels of gold), unless it contained a functional expression with the sense of 'the gold of,' as it occurs in 'the gold of her wedding ring.'

But in the light of this, the Fregean pattern of explanation seems to have as much plausibility for 'gold' as it has for 'shape' or 'nationality.' The predicate 'x is gold' is to be understood as meaning 'for some y, x is the gold of y,' and 'x is the same gold as y' as 'for some z, for some u, x is the gold of z and y is the gold of u and z is constituted of the same gold as u,' understanding 'the gold of' in such a way as ensures the equivalence of 'the gold of x is the same as the gold of y' and 'x is constituted of the same gold as y,' where 'is constituted of the same gold as' expresses an epistemologically prior relation in the same way as do 'has the same shape as' and 'has the same nationality as.'

If these suggestions are correct, Geach's derelativization thesis is far too ambitious: there are many substantival terms which are counter-examples. It does not follow, of course, that there are no substantival terms to which it *does* apply. And, in fact, it might seem that it must apply to what, following Dummett, can be called 'basic count nouns'; that is, substantival terms which are (a) not abstract nouns (like 'nationality' and 'shape'), (b) not mass nouns (like 'gold'), and (c) not derivative count nouns (like 'father' or 'postman'). For in the case of such basic count nouns it seems that the association with a criterion of identity which is definitive of a substantival term can be made in no other way: it cannot, as in the case of derivative count nouns, be derived from an association with a second count noun in terms of which the first is defined; nor can it, as in the case of abstract nouns and mass terms, be made in the way the Fregean pattern suggests, which requires that the associated criterion of identity be an equivalence relation between objects *other than* those to which the count noun applies.

However, once again Dummett suggests an alternative pattern of explanation. In the case of basic count nouns, he suggests (1981; 1991) the crucial point to recognize is that the associated criterion of identity is not an equivalence *relation* at all (where a relation is thought of as holding between *objects*).

We cannot give a correct representation of that level of our language at which we quantify over and refer to objects, Dummett thinks, unless we recognize a lower level at which no reference to or quantification over objects exists; formalized languages serve only to regiment the higher level. At the lower level, what takes the place of the use, at the higher level, of proper names and other singular terms to refer to objects is the use of demonstrative pronouns in what Dummett calls 'crude predications.' The distinctive feature of this use of demonstratives is that no criterion of identity has to be invoked to make their utterance understood; no answer to the question 'This what?' need be available. In such crude predications the predicate cannot, therefore, be one applicable to an object, but must be one expressing what Strawson has called a 'feature-placing concept.' Examples of such crude predications are 'This is sticky,' 'This is red,' and 'This is smooth.'

The transition to the higher level, at which reference to and quantification over objects takes place, Dummett suggests, is mediated by what he calls 'statements of identification,' that is, statements of the form, 'This is the same X as that' where 'X' is a basic count noun. A child does not actually acquire the word 'cat' in the first place by learning to point simultaneously to, say, the head and tail of a cat, and to say, 'That is the same cat as that.' But this, nevertheless, correctly represents what is involved in the move from the lower level of language to the higher, namely the acquisition of a criterion of identity by which we can determine where one cat leaves off and another begins.

But a statement of identification, like a crude predication, does not *itself* involve any reference to objects, since in itself it is merely a crude relational statement like 'This is darker than that.' Hence the criterion of identity associated with a basic count noun is not an equivalence relation between objects, either objects of the sort to which the count noun applies, or objects of another sort: '… is the same X as …,' as used in statements of identification, is *like* an expression for an equivalence relation, but it does not stand for such a relation, since it is not, at this stage, used to express a relation between *objects* at all. To grasp the criterion of identity associated with a basic count noun, it is thus not necessary to have any prior conception of objects of any sort. To think otherwise, Dummett suggests, is Geach's basic mistake.

These suggestions of Dummett's seem entirely correct. But it is important also to see the extent of the agreement between Dummett and Geach. The main emphasis of Geach's work on identity has always been on the unusability of an absolute identity relation as a *criterion* of identity. It is customary in the literature (see Chapter 39, OBJECTS AND CRITERIA OF IDENTITY, §5) to distinguish two forms of identity criteria, one-level and two-level. A two-level criterion of identity specifies the criterial relation as a relation holding between entities other than those for which the criterion is being given. Frege's criterion of identity for directions or the Fregean criterion of identity for shapes just explained are examples. A one-level criterion of identity states the criterion of identity for a type of object as a relation between objects of that very type: thus it says, for example, that classes are the same if and only if they have the same members or events are the same iff they have the same causes and effects. In a two-level criterion the criterial relation specified is a relative equivalence relation. And Dummett in effect repudiates the legitimacy of one-level criteria. According to his suggestions, the criterion of identity associated with a substantival term must either be given by an expression for a relative equivalence relation not holding between the objects to which the general term applies, or it must be given by an expression which does not designate a relation, *a fortiori*, not an absolute equivalence relation, at all.

A one-level criterion of identity, of the type Dummett implicitly repudiates as a legitimate criterion of identity, takes the form:

If x is an A and y is an A then x = y if and only if Rxy.

This is equivalent to the conjunction of:

(1) If x is an A then Rxx

and

(2) If x is an A, everything which is an A and R-related to it is identical to x.

Thus it amounts to:

(3) Anything which is an A is the A which is R-related to it.

In this the definite description must be understood in Russell's original fashion. So this gives a necessary condition for being an A by way of giving a criterion of identification for every A.

There are thus three points to be made about such one-level 'criteria of identity,' which confirm Dummett's repudiation of them as properly speaking criteria of identity at all. First, they merely give necessary conditions for falling under the sortal concepts they inform us about, that is, they contribute to the specification of the extensions of the sortal predicates, they do not specify (absolute) identity conditions in addition, or tell us what identity consists in for things of the sort. Second, one cannot infer from the fact that the one-level criterion of identity for As does not guarantee identity for Bs that As are not Bs. It does not follow from the fact that the one-level criterion of identity for classes, for example, does not guarantee property identity that classes are not properties (Cartwright, 1967; Geach, 1972). Third, it is only because the criterial relation specified is a relative equivalence relation that a one-level 'criterion of identity' for things of a sort says anything that is not true equally of things of every sort. More precisely, it is only because the relation specified is a relative equivalence relation that (2) adds anything to (1), in which no expression for identity occurs at all. Thus while classes are the same iff they have the same members, and events perhaps the same if and only if they have the same causes and effects, the thought that these are 'criteria of absolute identity' of a type incompatible with Geach's central thesis of the sortal relativity of identity is mistaken.

If Dummett is correct, Geach is right to deny that an absolute equivalence relation can serve as a criterion of identity: the criterion of identity associated with a general term (and hence, derivatively, with a proper name) must either be given by an expression for a relative equivalence relation not holding between the objects to which the general term applies (as in the case of abstract nouns and mass nouns), or it must be given by an expression which does not designate a relation between objects at all, and *a fortiori* does not designate an absolute equivalence relation. This, I would suggest, is the most important lesson to learn from Geach's work.

De Jure Codesignation

JAMES PRYOR

This chapter surveys a novel kind of semantic structure that has been posited by Mark Richard, Kit Fine, Ángel Pinillos, and others. Their commitments will be explained as we proceed. I discuss four potential areas of application:

- §1 focuses on anaphora, especially cases that can't be handled by a "bound-variable" analysis ("strict" and donkey sentences). I also distinguish our target view from other treatments of anaphora.
- §§2 through 6 discuss the semantics of attitude reports.
- §6 also contrasts two kinds of complex anaphoric dependency. (This may overlap in part or whole with the phenomena mentioned in §1.)
- §7 explains a difference in how functions in a programming language can be sensitive to the identity of their operands.

1

Our stage is set by a range of stances philosophers and linguists have taken to a series of sentences. Consider first:

(1) `Cicero admired Tully.`

(Throughout this discussion, I'll treat `admire` and other transitive verbs as extensional.) Consider next:

(2a) `Cicero admired him` (pointing at a bust of Marcus Tullius Cicero, here also claimed to be doing the admiring).

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

or:

(2b) He (pointing at the bust) admired Cicero.

Sentences (2a) and (2b) do not have to be produced, or understood, in ignorance of the fact that Cicero is the one being demonstrated. They might be embedded in a larger discourse like so:

(2c) Cicero was too proud to admire other people, but Cicero admired him (pointing), so he (continuing to point) must be Cicero.[1]

Contrast the way the pronoun him works in (2a) and (2c) with the way it works in:

(3a) Cicero divorced the woman who bore him children.

Here him is meant to be, and should be understood to be, anaphoric on the occurrence of Cicero, and hence to *derive its value from* that antecedent expression.[2] If we generate a sentence that parallels (1) and (2a), but with this anaphoric relation between the pronoun and Cicero, we get:

(3b) Cicero admired himself.

There are complex grammatical constraints on when anaphoric pronouns must or must not take reflexive morphology (himself rather than him). For our purposes, observe that pronouns can be understood as anaphoric without the presence of that morphology, as in (3a), or:

(3c) Cicero's wife disappointed him.
(3d) Terentia betrayed Cicero, so he was unhappy.
(3e) Cicero mourned his daughter.

Examples like these are sometimes hypothesized to be ambiguous. For example, (3e) might state that Cicero has the reflexive property $\lambda x.\ x$ mourned x's daughter, or that he has the relational property $\lambda x.\ x$ mourned Cicero's daughter. The latter reading would be required if the his were demonstrative and just happened to designate Cicero, as in (2a) and (2b); but it's also available when his is anaphoric. If there are these two readings of (3e), they'd underwrite an ambiguity that's widely agreed to be present when the sentence continues:

(4a) Cicero mourned his daughter, but Atticus didn't.

Are we talking about Atticus mourning Atticus's own daughter, or about his mourning the same person Cicero did? For historical reasons, linguists call the first reading "sloppy" and the second "strict."[3] The "sloppy" reflexive *reading* of these sentences should not be confused with the reflexive *morphology* exhibited in (3b). As we've just seen, the reading can be present without that morphology. Further, the morphology doesn't force that reading:

(4b) `Cicero admired himself, but Atticus didn't.`

can also be read "strictly," as saying that Atticus didn't admire Cicero.[4]

Our stage consists of stances philosophers and linguists have taken to examples like (1) and (2ab), on the one hand, versus examples with anaphora like (3a–e), and perhaps also:

(5) `Cicero admired Cicero` (meant and understood to involve a recurring use of a single name).

Bracketing examples like (5) for a moment, one stance toward the (3) examples is represented by Lasnik (1976) and Bach (1987, chs 11–12). These theorists deny that anaphoric relations generally have any distinctive syntactic or semantic manifestation. In essence, they'd treat the (3) examples on the same model as (2ab).[5]

A second stance is exemplified by Salmon, Soames, and some other theorists. They embrace three commitments, the first of which I'll label:

(Z1) So far as possible, analyze "sloppy" reflexive readings using bound variables.

That is, they'd take (3b), when so read, to have the form:

(3b′) ($\lambda x.$ *x* admired *x*) Cicero

It's controversial how far such analyses can be applied. Salmon and Soames deny that (5) has this form. That denial is consonant with the fact that continuing (5) with `but Atticus didn't` only allows a "strict" reading.

Restricting our attention to examples that *do* have "sloppy" readings, it's controversial whether a bound-variable analysis can account for all of them. (3d) is less hospitable to such an analysis than (3abe), and examples with "donkey pronouns" like:

(6) `Every orator who had a daughter loved her.`

are widely agreed to resist it: `her` is outside the syntactic scope of any binding introduced by `a daughter`. Yet such sentences still support "sloppy" readings:

(7) `Every orator who had a daughter loved her, but some consul who had a wife didn't.`

meaning the consul did not love his wife.[6]

Salmon and Soames also hold:

(Z2) Propositions of the form ($\lambda x.$ *x* admired *x*) *a* are distinct from propositions of the form ($\lambda x.$ *x* admired *a*) *a* and ($\lambda x.$ *a* admired *x*) *a*.

and:

(Z3) Attitude verbs like `believe` express a dyadic relation between a subject and the proposition expressed by their complement clause.

In light of (Z2), this has the consequence that attitude reports like (8ab) differ in meaning (and, on their view, in truth-conditions) from reports like (9abc):

(8a) `Anita believes that someone admired himself.`
(8b) `Anita believes that (λ`*`x`*`. `*`x`*` admired `*`x`*`) Cicero.`
(9a) `Someone is such that Anita believes that he admired him.`
(9b) `(λ`*`x`*`. Anita believes that `*`x`*` admired `*`x`*`) Cicero.`
(9c) `Anita believes that (λ`*`x`*`. `*`x`*` admired Cicero) Cicero.`

When the binding quantifier or λ operator is inside the complement, as in (8ab), Salmon and Soames say the report relates Anita to a content from which (in any guise) she could infer:

(10) `Someone admired himself.`

When it is outside the complement, as in (9ab), or the binding pattern is as in (9c), they deny that such a content is attributed to Anita. For all that (9abc) say, on their view, Anita may merely be willing to assent to sentences like (1).[7]

At several points in this discussion, I will need to invoke this notion of "contents from which one could infer (something like) (10)." Let's call them "cyclic" contents and thoughts.[8]

The third stance in our drama takes inspiration from an idea of Putnam's that (1) and (5) have different "logical structures." This idea was cultivated by Mark Richard in the 1980s and 1990s, and has been developed in different shapes more recently by Kit Fine and by others.

This stance agrees with Salmon and Soames that there's interesting semantic behavior present in (at least some readings of) examples like (3b) that's absent from (1) or (2ab). But these new theorists recognize among such behavior a pattern that extends also to the "strict" readings of the anaphoric examples, and may also be present in (6) and/or (5). Roughly, their idea is that *all* these examples have cyclic contents, whereas with (1) and (2ab) no inference to a claim like (10) is semantically underwritten.

The sense in which claims like (10) may be "inferable" for a subject, or "semantically underwritten," is not straightforward. This must mean something more than a mere metaphysical entailment, since we already have that with (1). It must also mean more than that the consequence is intended by the speaker, or follows given what's presupposed in the discussion (see note 1 above). With (2c) we'd already have (10) be entailed in those senses. Instead, claims like (10) presumably must follow *from the conventional meaning* of the sentences we're considering (when used in the way we're considering), in a way that full competence with the sentences (so understood) requires one somehow to be sensitive to. OK, but what does that "requirement to be sensitive" amount to? At this juncture, proponents of the third stance reach for ideas like "what a speaker can know *a priori*," or "what a speaker would be immediately justified in believing" on the basis of their understanding. But the first idea threatens to let in all sorts of substantive mathematics that shouldn't be

part of the linguistic competences we're trying to explicate. And the second idea provokes worries about speakers who have no semantic concepts, or speakers who do but endorse false semantic theories (perhaps justifiably).

We will return to issues about the epistemology of language use later. Rather than begin with any specific theory here, I propose we just content ourselves for now with an intuitive understanding of the proposal that the (3) examples are cyclic on both their "sloppy" and "strict" readings, that is, that they *somehow* semantically underwrite inferences to claims like (10). Proponents of this stance can allow "sloppy" and "strict" readings to have different contents, but they'll say that the behavior just described is at least interestingly shared by them; and they'll insist that the "strict" readings have contents different from those in the (2) examples. As I said, this same strategy may be extended to other examples like (6) and/or (5).[9]

The syntax and semantics of our (3) examples is contested, so it's not obvious that the "strict" readings of these examples *need to* end up with their own distinguished contents, from which claims like (10) could be inferred. But that is the view our third stance will defend.

If patterns like the ones we're considering are acknowledged to be semantically encoded, what difference should that make, for example to the truth of attitude reports that embed these sentences as complements? This is a contested issue that we'll explore below.

Here are some more examples that may exhibit the envisaged patterns, where this also can't be the result of the kind of binding structure exhibited in (3b′). First:

(11a) `Only Cicero mourned his daughter.`

This is ambiguous between:

(11b) `Cicero, and no one else, mourned the daughter of Cicero.`
(11b′) (λ*x*. *x* mourned Cicero's daughter) Cicero; and no one else _____

and:

(11c) `Cicero, and no one else, mourned that person's own daughter.`
(11c′) (λ*x*. *x* mourned *x*'s daughter) Cicero; and no one else _____

where the _____ indicates that a "matching" predicate has been deleted or elided, namely the λ-term from the first conjunct. Yet it's not only (11c) that conventionally encodes that it's the same person who both mourned and was the father. The other reading should also encode this.[10]

Second:

(12) `Terentia didn't admire Cicero, but he/Cicero did.`

It's most natural to analyze this as:

(12′) ¬(λ*x*. *x* admired Cicero) Terentia; but _____ Cicero

Not as:

(12″) ¬(λ*x*. *x* admired Cicero) Terentia; but (λ*x*. *x* admired *x*) Cicero

because on current theories of ellipsis, such non-matching λ-terms would not license the surface form (12).[11] Nor should we analyze it as:

(12‴) (λ*y*. ¬(λ*x*. *x* admired *y*) Terentia; but _____ *y*) Cicero

That would posit a syntax and predicate structure more complex than we have independent evidence for. Yet the second conjunct of (12) does seem to conventionally encode that it's the same person who both admires and is admired. So it should be possible for this to happen even when the binding structure is as in (12′).[12]

Third:

(13) `Terentia preferred Cicero to every politician that he/ Cicero did.`

It's most natural to analyze this as:

(13′) ∀*p* : _____ Cicero. (λ*x*. *x* preferred Cicero to *p*) Terentia

Not as:

(13″) ∀*p* : (λ*x*. *x* preferred *x* to *p*) Cicero. (λ*x*. *x* preferred Cicero to *p*) Terentia

Yet the restriction on the quantifier of (13) does seem to conventionally encode that it's the same person who both prefers and is ranked first. So it should be possible for this to happen even when the binding structure is as in (13′).

In summary, the third stance thinks we need to go beyond the bound-variable analysis to capture the pattern they're attending to, and want to argue is semantically encoded. This chapter will survey some further motivations for, and distinctive claims made by, this stance.

2

Let's go back to the early 1950s. Carnap had recently proposed that sentences are synonymous, and express the same belief, iff they are "intensionally isomorphic": that is, they have parallel constructions with corresponding atomic elements always having the same intension. Carnap had also proposed that a report in English attributing `believes that` *S* is true iff there is a language *L* and sentence *T* such that *S* in English is intensionally isomorphic to *T* in *L*, and the subject is disposed to assent to *T* as a sentence of *L*.

In the early 1950s, Church and Mates pressed several objections against these proposals. Among other things, Church (1950) complained that Carnap's analysis wrongly characterizes ordinary beliefs as being "about sentences"; he preferred analyses that instead relate

believers to propositions. Such analyses would translate more convincingly into other languages. Church (1954) argued that intensional isomorphism is anyway too weak for Carnap's purposes, since it tolerates the substitution of non-synonymous expressions with the same intension. Yet such substitutions seem to change the truth-value of attitude reports. Church favored working with a notion of "synonymous isomorphism" instead. Mates (1950) complained that even with a tighter synonymy relation between distinct sentences *S* and *S′*, one can still always embed them:

(14a) `Whoever believes that S, believes that S.`
(14b) `Whoever believes that S, believes that S′.`

in such a way that speakers can intelligibly assent to one embedding while doubting or dissenting from the other. Here is an example:

(15a) `Whoever believes that lawyers are wealthy, believes that lawyers are wealthy.`
(15b) `Whoever believes that lawyers are wealthy, believes that attorneys are wealthy.`

I know that lawyers and attorneys are the same. But conceivably, some subjects may suspect that they aren't. I may regard such subjects as counter-examples to (15b), and for that reason be unwilling to assent to it. Carnap's strategy (even as refined by Church) must count subjects like them (and me) as nonetheless *having* beliefs reportable with complement clauses that they'd resist assenting to.[13]

Putnam (1954) defends Carnap's strategy against some of these objections. Against Church, he claims that multiple analyses can be correct and yet not intertranslatable. Crucial for our purposes is Putnam's response to Mates, which involves re-defining "intensionally isomorphic" so as to be sensitive to differences like those exhibited between (15a) and (15b), or (5) and (1). Here is Putnam's own example:

> "Greek" and "Hellene" are synonymous. But "All Greeks are Greeks" and "All Greeks are Hellenes" do not *feel* quite like synonyms. But what has changed? Did we not obtain the second sentence from the first by "putting equals for equals"? The answer is that the *logical structure* has changed. The first sentence has the form "All F are F," while the second sentence has the form "All F are G" – and these are wholly distinct … (Putnam, 1954, pp. 153–154)

Putnam's idea here is that the meaning of a sentence is not *just* a function of the meaning of its parts, but also of the sentence's "logical structure," and that Mates had been assuming too simple an account of that. If we instead work with a notion of structure that's sensitive to the recurrences of terms (see Putnam's n. 10), so that the difference exhibited by `All F are F` and `All F are G`, and presumably also by `Cicero admired Cicero` and `Cicero admired Tully`, are semantically significant, then these sentences as wholes will be non-synonymous, even though their individual words pairwise are synonymous.

This idea of Putnam's was seconded by Kaplan and elements of it can also be found in Geach.[14] Below, I'll first explain the modern development of the idea in Richard's and Fine's work, and then §5 will more briefly survey some other places it appears. The authors we'll consider don't all work out Putnam's guiding idea in the same way, and they use varying terminology: "logical potential" (Taschek), "co-relativized" terms (Richard), "coordination,"

"representing as the same," and "strict coreference" (Fine), "explicit coreference" (Taylor), "coindexed expressions" and "grammatically determined coreference" (Fiengo and May), and "*de jure* coreference" (Schroeter, Pinillos, Recanati). The last phrase seems to be trending most strongly, so I've based this chapter's title on it. I prefer to say "codesignating" rather than "coreferring," though, as to some the term "referring" has specific connotations that aren't essential to the phenomena we're exploring (even after we restrict our attention to singular terms, as we will here). These readers would resist talk about variables or anaphoric pronouns *referring*. "Designating" is more readily understood to have the needed generality.

3

Richard's engagement with Putnam's idea begins in his (1983). This paper became famous for its phone-booth scenario, which presented an intuitive difference in acceptability between:

(16a) `I believe that you are in danger.`
(16b) `The man watching you believes that you are in danger.`

despite the fact that these differ only in the substitution of codesignating expressions *outside of* any opaque context.[15] That point was only subsidiary to Richard's main goal in the paper, though, which was to explore the idea that:

(17a) `I can inform you of her danger via the telephone.`
(17b) `I can inform her of her danger via the telephone.`

differ semantically in such a way as to not be substitutable in the complements of attitude reports. For Richard at this time, sentences (17a) and (17b) do have the same *content*, but he makes the attitude verbs they may be embedded under become sensitive to their differing *character*. (We won't dwell on the details of how this works, because as we'll see, Richard soon moved to a different and more general strategy.)

Sentences (17a) and (17b) are of the form `...you...her...` and `...her...her...`, where all the pronouns are codesignating, and thus they parallel our examples:

(1) `Cicero admired Tully.`
(5) `Cicero admired Cicero.`

The only differences are that in Richard's examples, the pronouns occur in what may arguably be an intensional context (`inform _____ of her danger`) – this plays no role in his discussion – and his examples concern pronouns rather than proper names. This limitation was essential to the proposal he advanced in the 1983 paper, but was lifted when he developed these ideas further (and differently) in his 1990 book.

Richard (1987) begins to extend his claims about (17ab) to the open (quasi-English) expressions:

(18a) `Juan said that (he observed` *x* `and then` *y* `but he wanted to observe` *y* `and then` *x*`).`
(18b) `Juan said that (he observed` *x* `and then` *y* `but he wanted to observe` *x* `and then` *y*`).`

and:

(19a) Juan said that (*x* chased *y* and then *y* chased me).
(19b) Juan said that (*x* chased *y* and then *x* chased me).

arguing that each pair may differ in truth-value even when the variables *x* and *y* are assigned the same designation. The formal mechanisms Richard proposed in (1983) won't explain this result, since the variables don't differ in character. We don't get Richard's developed account of how this might work until Richard (1990). (Similar examples are discussed there at pp. 153, 200ff.)

Richard (1986–1987) offers an intermediate story, introducing a construction he calls "R-structures" (these are akin to the DRSs used in Kamp, 1984–1985; 1990; and Asher, 1986; 1987; 1989). We won't dwell on the details of these either. But I do want to point out several elements in this paper that will reappear in later contributions by Richard and others. First, Richard proposes:

> Let us talk of two occurrences of a term being co-relativized, when they are treated as if they were occurrences of the same existentially bound variable.
>
> (Richard, 1986–1987, p. 251)

Second, Richard associates several "levels" of information with a report (1986–1987, pp. 253ff.). The first level is initially described as just the Russellian content of the complement (pp. 244, 253) but then later is said to be that complement's R-structure (p. 256). This means that it will encode patterns of how terms recur in that complement. The second level encodes patterns of how terms recur in *multiple* reports, within a larger discourse. This roughly corresponds to Fine's "weak *de dicto*" reading of reports, which we'll discuss later. The third level encodes patterns of how terms recur *also in our unspoken background convictions* about the attitudes of others (pp. 257ff.). We will see something like this in Fine and other authors, too. In this paper, Richard only regards the first of these levels as giving the strict truth-conditions of the report (pp. 244, 256).

The account of attitude reports Richard arrived at in his (1990) is complex, and will be best understood against the background of other views in the air at the time.

Instead of the Fregean strategy of having beliefs and other attitudes be relations to a single fine-grained object, many philosophers in the 1980s began following Kaplan's and Perry's suggestion to think of attitudes as relations to *both* a coarse-grained Russellian proposition, *and* something that added additional grain, such as a *guise* under which that proposition is grasped, or a *sentence in Mentalese* which expresses it, or a series of *mental files* deployed in thinking it.[16] For concreteness, let's work with the Mentalese sentence version of this idea. So the underlying facts about a subject, that a belief report would aim in some way to describe or summarize, would be that he stands in some belief-like accepting/endorsing relation to a coarse-grained Russellian proposition about Cicero and admiring *with* some Mentalese sentence like `Cicero admires Tully`. *Exactly how* belief reports aim to describe or summarize these underlying facts, different theorists gave different accounts of. To help separate what these accounts agreed about from the different proposals they offered of the predicate `believe`, let's call the underlying belief-like accepting/endorsing relation "doxizing." One doxizes a Russellian proposition with a Mentalese sentence.

Salmon (1986a) offered a straightforward account of the relation between doxizing and the predicate `believe`: in the terms we're employing here, his view was that a report:

(20) `Anita believes that` *S*.

is true iff *there exists some* Mentalese sentence *T* such that Anita doxizes the Russellian proposition expressed by *S* with that sentence *T*.[17] Salmon is not always explicit whether this is meant to be an account of the *logical form* of the belief report, or only its truth-conditions. On the first construal, belief reports would themselves contain existential quantifiers over Mentalese sentences (or guises); these would just have no overt pronunciation. Also, the predicate `believe` would itself really contribute a triadic semantic value, contrary to its surface appearance. Some have interpreted Salmon this way;[18] but the balance of evidence speaks more strongly for the other construal, where `believe` really only contributes an atomic dyadic relation, as it appears to (see Salmon, 1986a, pp. 5–6, and clauses 35–36 on pp. 146–147; also his 1986b, pp. 32–33), and the existential quantifier only enters into Salmon's explanation of the report's *truth-conditions*, not its actual syntax or semantic structure.

Many theorists agreed with Salmon that in at least some cases, belief reports are completely non-committal about how (with what kind of Mentalese sentence) their subject doxizes the attributed proposition. But these theorists resisted saying that it was *always* so. In many other cases, they claimed, belief reports make more specific commitments about the third argument of the doxizing relation. Many went no further than that, saying only that the particular complement clause used in the belief report is meant to somehow "display" (without designating or literally expressing) the kind of Mentalese sentence the subject doxizes with.[19] But a handful of theorists made specific proposals about how belief reports constrain or supply the extra argument.

The earliest of these proposals came from Schiffer, who suggested that (20) be analyzed as:

(20′) $\exists T\,(\phi T \wedge \text{Anita doxizes } \sigma \text{ with } T)$

where σ is the Russellian proposition expressed by *S*, and *T* is a Mentalese sentence or guise meeting some condition ϕ (see esp. Schiffer, 1977; 1992). Because ϕ is a contextually supplied element that isn't overtly designated, views of this style became known as "hidden indexical theories" (HITs). I will refer to this as "Schiffer's HIT," though he doesn't straightforwardly endorse the view. He merely says it's the best option if you want to embrace compositionality about what complement clauses express. Over the course of many papers, Schiffer voices a series of objections against "his" HIT.[20] Three of these I'll mention just in passing: we shouldn't advocate such a view for speech reports, there are no good candidates to play the role of "guises," and the view would need supplementation to deal with empty names. Three other objections it would be useful to refer to later, so I'll label them:

S1 the "meaning-intention" problem: Ordinary speakers aren't aware of quantifying over, describing, or designating guises. So it's implausible that they have the semantic intentions they'd need to have, if a HIT of attitude reports were correct.

S2 the "logical form" problem: Schiffer's HIT analyzes `believe` in terms of the triadic predicate `doxize`. But Schiffer says that syntactic evidence, and ordinary intuition, speak against analyzing `believe` as having more arguments than just a subject and a complement (plus perhaps a time, which we're here ignoring). This complaint is discussed further in Ludlow (1995), Schiffer (1996), and Ludlow (1996).

S3 the "validities" problem: The argument `Anita believes everything Juan says; Juan says that Cicero is alive; so Anita believes that Cicero is alive` seems intuitively to be valid. But if the first premise says merely that if Juan says σ, Anita will doxize σ under *some guise or other*, then the premises don't entail a conclusion that constrains how Anita doxizes. If on the other hand, the first premise says that Anita will doxize σ *under the same guise that Juan says it*, then the conclusion follows only if it involves the same guise that's invoked in the second premise. And Schiffer's HIT doesn't guarantee that it will. (On his account, the premise and the conclusion will each have their own $\exists$.)

Crimmins and Perry *do* endorse a version of HIT.[21] On their account, though, speakers often directly specify the subject's Mentalese sentence *T*,[22] rather than contextually supplying a condition ϕ that restricts a quantifier over *T*. Though *T* is directly specified in *that* sense, it still is not designated by any pronounced syntax: in Perry's terminology, it's an "unarticulated constituent" of the report.[23]

Recanati (1993, chs 18–20; 1995) defended a view with important similarities to Schiffer's and Crimmins's HITs, but also some notable differences (Crimmins, 1995c, pp. 201–203, compares their views). Like the others, Recanati wanted belief reports to often assert, and not merely implicate, constraints on how (with what Mentalese sentence or guise) the subject doxized. Also like the others, and unlike Fregeans, he wanted component expressions of the report's complement to have their ordinary designations – thus making it unproblematic to say things like `Anita believes that Cicero is alive, but he isn't`. The strategy Recanati pursues to reconcile these goals is not to make the predicate `believes` take a third argument, which the report quantifies over or contextually supplies. Instead, he proposes that the complement clause as a whole usually expresses an enriched, "quasi-singular" proposition that correlates ordinary designata (like Cicero) with the subject's Mentalese representations of them.[24] For example:

(21) `Anita believes that Cicero is alive.`

might express:

(21′) ⟨a dyadic believing relation, Anita, ⟨the property of being alive, (Cicero, *the mental representation of Cicero that Anita associates with the name* `Cicero`)⟩⟩

Recanati denies that the enrichments are determined by the conventional meaning or the truth-conditional content that `Cicero is alive` would express in isolation. Rather it depends on the context of the report, including previous conversational moves and other specifics about how that sentence is embedded. (For example, it may depend on how we designate Anita.)

Recanati's view will help us contextualize Richard (1990). The spirit of the theory Richard develops there and in later work[25] is reminiscent of Carnap's account from §2 above:

> [W]hen we ascribe a belief saying `so and so believes that` *S*, we offer the sentence *S* as a *representation* or *translation* of what realizes one of so and so's beliefs. Attitude ascription thus presupposes something like a "translation manual," one keyed specifically to the individuals to whom attitudes are ascribed … The semantic rule governing belief ascriptions is something like: *x* `believes that` *S*, used in a context *c*, is true just in case *S*, relative to context *c*'s translation manual, translates some belief-realizing state of (the referent of) *x*.[26]

Concerning Richard's use of "translate," this should not be understood to mean that the expressions in the report have to be *conventional* translations of any expressions the subject would accept (see, e.g., 1990, pp. 134–135). Concerning Richard's use of "represent," this can also be confusing. He uses that term in several ways. "Representations" are groupings of token Mentalese expressions from which (what I'll call) private RAMs are composed (pp. 181–190; this is defined below). This is related to Richard's "representational systems," which are sets of all a subject's private RAMs (p. 137). Another use of "represent" (invoked in the above quote) is for the relation that a public RAM stands in to the private RAM that is its image under a given correlation function (pp. 139, 144). Importantly, Richard (unlike Crimmins) doesn't think that reports *designate* or directly specify subjects' Mentalese representations.

We need to look at the details of how Richard spells this out. They place him somewhere between Schiffer and Crimmins, on the one hand, and Recanati, on the other. Like Recanati, Richard wants complement clauses to express something richer than mere Russellian propositions. But unlike Recanati, he wants a compositional story about what the complement clauses do express. And unlike Recanati and Crimmins, he thinks reporters generally don't transact with other subjects' specific Mentalese representations. So rather than have the complement of (21) express a proposition enriched with Anita's Mentalese, Richard proposes it's instead enriched with *the English name* `Cicero` that was used in the report.[27] At first (1989; 1990; 1993) he called these enriched propositions "Russellian Annotated Matrices" (RAMs), but later he calls them "articulated" (1995) or "sentential" propositions (2006). He calls the components of these RAMs – the pairings of individual words with their designations – "annotations."

How do we get from a proposition enriched with English vocabulary, which the report's subject need not understand, to information about how the subject does mentally represent Cicero? Let's call the RAM expressed by the report's complement the "public" RAM. Let's call the Mentalese RAMs, with which subjects are claimed to doxize, "private" RAMs. Richard posits "correlation functions" that take us from the public RAM to a private RAM. We can understand him as proposing that (21) expresses:

(21″) $\exists f\,(\phi f \wedge \text{Anita doxizes}^{\star}\ f(\sigma^{\star}))$

Here, doxizing* is a dyadic relation Anita stands in to private RAMs that she "accepts."[28] $\sigma^{\star}$ is the public RAM expressed by the complement `Cicero is alive`: the fusion of a Russellian proposition with those very English words. f is a correlation that takes us from $\sigma^{\star}$ to some private RAM. The report doesn't directly specify f, but it does supply restrictions ϕ, in a context-dependent and not-overtly-pronounced way. In this regard, the view resembles Schiffer's HIT.

I've introduced Richard's theory this way to highlight respects in which it agrees with Schiffer, Crimmins, and Recanati. But in fact this is not quite the form that Richard himself employs. Rather than have the context supply an argument ϕ, Richard instead folds the ϕ-role into the relation I called "doxizing*," giving a single (contextually varying) relation that I'll call "doxphizing*." So Richard's own version of (21″) looks more like:

(21‴) $\exists f\,(\text{Anita doxphizes}^{\star}\ \sigma^{\star}\ \text{under}\ f)$

The truth-conditions of this are the same as (21″). Because doxphizing* includes the contextual restrictions on acceptable correlations, Richard's account is one where the predicate

`believe` expresses different relations in different contexts. (On Schiffer's and Crimmins's HIT, by contrast, `believe` is not context-sensitive, though the report as a whole is; and on Recanati's account, it's the report's complement that's context-sensitive.)

Let me point out some details and refinements.

- Richard understands his *correlations* as functions that map annotations to annotations, in a way that in general must preserve Russellian content and sometimes has to also obey other contextual restrictions (captured above by ϕ or doxphizing*). What will be important for our discussion is that these are *functions* part of whose effect is to map *expression types* in the report language to types of Mentalese expressions (see Richard, 1990, ch. 3, n. 11; Crimmins, 1992a, pp. 191–192; Sider, 1995, p. 503; Soames, 1995, n. 12; 2002, ch. 7, n. 12).

  A consequence of this is that when (non-demonstrative) expressions recur in the report's complement, as `Cicero` does in:

  (5*) `Anita believes that Cicero admired Cicero.`

  then the report commits to the subject also having recurring Mentalese expressions in her private RAM (see Richard, 1990, pp. 138–140, 201–202, 217–219). Hence, (5*) attributes a cyclic thought to Anita, one from whose content she could infer:

  (10) `Someone admired himself.`

  This prediction should seem familiar from our summary of Richard's three earlier papers, at the start of this section. It corresponds to a claim I'll label F3 when discussing Fine. (Richard also says that complements containing pronouns like `himself` always attribute cyclic thoughts: 1990, p. 218.)

  As we'll discuss, these commitments are controversial. For example, we observed that Salmon and Soames only allow complements like (3b)/(3b′) to attribute cyclic thoughts. They deny that the complements of (9bc) or (5*) have that structure.

  The rest of Richard's account does not *force him* to understand correlations in the way described here. He could instead define them on expression *occurrences* (see Crimmins, 1992a, pp. 195–196; 1995a, p. 387), or he could work with *relations* here instead of functions (see Sider, 1995, §6). Then recurring expressions in a complement needn't attribute cyclic thoughts. But Richard made this choice deliberately: in part to underwrite the truth-conditions he predicted in the earlier papers, and for further reasons he spells out in (1993, pp. 117ff.).

  Eventually, though, Richard came to have second thoughts about this, and in (2013b, pp. 8–11) he suggests that for iterated reports, the commitment described above only holds for *one reading*. He also countenances other readings, that permit recurring expressions in the complement to be "indexed to a subject higher in the sentence," and thus to possibly "translate" diverse Mentalese expressions from a more proximal subject's private RAM.[29]

- The fact that Richard's presentation makes `believe` indexical gives him other troubles with iterated reports. Suppose I observe Juan asserting (21), and then, in another context, report `Juan said that Anita believes that Cicero is alive`. Since my context is not the same as Juan's, it's unlikely that we have the same restrictions on acceptable correlations. That means that `believe` in my mouth won't express the same doxphizing* relation that it did in Juan's mouth. This motivates Richard to propose

that `believe` in the complement of my report contributes *its character* rather than its content to my report's public RAM (1990, pp. 165–167, 245–246; 2006, pp. 259–60). (And so too for other attitude verbs.) This is why I said above that correlations "*in general* must preserve Russellian content": here we have some exceptions, where it's instead the expression's character that needs to be preserved.

This raises several issues. First, why make a special exception just for attitude verbs? Richard ends up suggesting a parallel treatment of gradable adjectives and some uses of expressions like `foreign` and `the local` (2006, pp. 260–262; 1993, n. 3). Second, this aspect of Richard's account leads him to a *relativist* view of attitude reports (1990, §4.4), where *the content* of a report needs a further contextual parameter before it is truth-evaluable. Richard welcomes this commitment (see further his 2008; 2015, chs 5–7), but others may not.

I will ignore this aspect of Richard's theory.

- In (21″) and (21‴) we had an $\exists f$ in the content of a single report. In fact Richard's considered view is that sometimes we only quantify over correlations *at the discourse level*, and thus might reuse the same correlation f in several reports (1990, pp. 143, 175–180, 235–243; see also 1986–1987, pp. 69ff.). This corresponds to a move I'll label F4 when discussing Fine, and helps answer Schiffer's objection S3 to HITs, mentioned above (see Richard, 1986–1987, pp. 69, 75; 1990, pp. 148–149; 1993, pp. 118–120; contrast Crimmins, 1995a, pp. 392ff. esp. n. 11). It also means that Richard is proposing that `believe` expresses a *triadic* relation (with an extra argument place for the correlation f supplied by the discourse). So he has to confront Schiffer's objection S2.

Most of the critical attention to Richard's theory focused on difficulties about how context is supposed to supply restrictions on correlations. Some authors made complaints reminiscent of Schiffer's objection S1 to HITs (see Saul, 1993; Clapp, 2000; Soames, 2002, ch. 7; also Richard, 1997, §11). Soames (1995; 2002, ch. 7) complained that Richard's initial account of restrictions gave reports implausible modal profiles. Sider (1995, §§2–4) and Soames (1995; 2002, pp. 179–191) described cases where conversants unwittingly accept conflicting restrictions in a single context, because they don't recognize a subject whose attitudes they're reporting under different guises (see also Nelson, 2005). These complaints pose serious challenges to Richard's theory, but they are orthogonal to the aspects of his theory that are interesting for this chapter, so I won't pursue them.

A handful of other critical discussions merit special mention. First is Soames (1987b, esp. §§6, 8). This addresses an early undeveloped version of Richard's views, but many of the complaints raised there are also ones Soames will raise against *Fine's* Putnam-inspired account. Second is Soames (1994), which discusses "sloppy" donkey anaphora (pp. 120ff.) and some examples we'll return to in §6 below. The third critical focus is a complaint that Church (1954, p. 165) made against Putnam's original proposal. Given the different "logical structures" that Putnam attributes to `All Greeks are Greeks` and `All Greeks are Hellenes`, the latter would turn out to be *inexpressible* in a language that has only a single predicate synonymous with `Greek` and `Hellene`. Church found this intolerable. I'm not sure that judgment is underwritten by our actual practice and assessment of translation. But it is a judgment that Salmon shares and attaches great weight to (Salmon, 1986a, ch. 4, n. 4; 2001, pp. 582ff.; 2010, n. 11; 2012, pp. 437–438). See also Soames (1987b, pp. 113–114). Richard addresses those kinds of complaints at (1990, pp. 155, 160–162, 167–171).

4

(Unless otherwise indicated, page references in this section are all to Fine 2007.)

Fine's engagement with Putnam's idea[30] began in his (2003), which developed into chapter 1 of his 2007 book. The problem that concerns him there is how to account for the semantic role of the variables *x* and *y*. One the one hand, they seem to function semantically the same. We understand the two sentences:

$$\forall x Fx \quad \forall x Fy$$

to have the same meaning, and so too the two predicates:

$$\lambda x.Fx \quad \lambda y.Fy$$

and arguably we should also so regard the two open formulas:

$$Fx \quad Fy$$

and the mere variables themselves:

$$x \quad y$$

On the other hand, the predicates:

$$\lambda x.Rxx \quad \lambda y.Rxy$$

have different meanings, and arguably so too should the open formulas:

$$Rxx \quad Rxy$$

Fine's way of distilling this issue is to say that whereas the two single variables *x* and *y* have the same semantic role, the *pair* of variables *x*, *x* has a *different* semantic role from the pair *x*, *y*. Fine explores existing accounts of the semantics of variables and argues that none of them do justice to that idea in a philosophically satisfying way. For example, one account will give each of the variables *x* and *y* as their semantic value the set of objects they range over. But applying that to the pairs *x*, *x* and *x*, *y* would give them the same meaning. We could solve that by giving *x* as its meaning instead *the pair of itself plus* the set of objects it ranges over; and similarly for *y*. Or less artificially, we could give *x* as its meaning a function from assignment functions *g* to the object that *g* assigns to *x*; and similarly for *y*. Those approaches *would* give the pairs *x*, *x* and *x*, *y* different meanings, because they'd give each of the variables on its own a different (though analogous) meaning. Fine's objection to this is not a *direct* insistence that *x* and *y* on their own must get *exactly the same* meaning. Rather it's that such proposals are philosophically unsatisfying, because:

> [T]he posited difference between the semantic values for *x* and *y* simply turns on the difference between the variables *x* and *y* themselves … [W]hat we secure on this approach, strictly speaking, is not a *semantic* difference, one lying on the non-conventional side of language, but a *typographic* difference, one lying purely on the conventional side of language. (p. 11)

Fine criticizes other proposals in a variety of ways.

His own solution gives up the idea that expressions can be given any meaning *on their own* that settles what the meaning of pairs (or longer sequences) of expressions is. Instead of determining the meaning of *x*, *y* as built from the intrinsic meanings of its parts, he proposes a theory that determines the meaning of *x*, *y* as in the first place given by how those expressions are *semantically related* (see esp. pp. 3, 22–24). Note that a relation between *x* and *y* (such as codesignating Cicero) can be re-factored into a function from the pair *x*, *y* to the presence or absence of the relevant semantic attribute; thus we can also understand Fine to be assigning semantic values to *sequences* of expressions, rather than (only) to expressions taken individually. (Fine prefers to call these "semantic connections" rather than "semantic values," but I will stick with the more traditional vocabulary.) As Fine's account evolves to handle binding variables with quantifiers, we get the revision that it's not mere sequences of expressions, unadorned, that get assigned values, but rather these together with a "coordination scheme" mandating that some free occurrences of the same variables in the sequence be interpreted the same. (This is to capture the different ways that our interpretation of $(\forall xFx) \wedge Gx$ and $\forall x(Fx \wedge Gx)$ will depend on the interpretation of the sequence *x*, *Fx*, *Gx*.) Fine proposes to generalize the approach that assigns to each variable the set of objects it ranges over. Instead he will assign to each *coordinated sequence of* expressions a set of *sequences of* semantic values.

Fine does not give a full and explicit semantics for his language, but here is what I understand him to be proposing.[31] See also Pickel and Rabern (forthcoming, §2).

- $[\![\ldots, R, \ldots]\!]$ = {(…, *R*'s extension, …) | for each interpretation of the rest of the original sequence of expressions }
- $[\![\ldots, \underline{x}, \ldots, \underline{x}, \ldots]\!] = \{(\ldots, d, \ldots, d, \ldots) \mid d$ any object in the domain *x* ranges over, for each interpretation of the rest of the sequence }
- $[\![\ldots, x, \ldots, x, \ldots]\!]$, where the occurrences of *x* are not linked = {(…, d_1, …, d_2, ….) | d_1 , d_2 any objects in the domain *x* ranges over, for each interpretation of the rest of the sequence }
- $[\![\ldots, Rt_1t_2, \ldots]\!] = \{(\ldots, \text{true}, \ldots) \mid [\![\Sigma]\!]$ contains (…, Δ, d_1, d_2, …) such that $(d_1, d_2) \in \Delta\} \cup \{(\ldots, \text{false}, \ldots) \mid [\![\Sigma]\!]$ contains (…, Δ, d_1, d_2, …) such that $(d_1, d_2) \notin \Delta\}$, where Σ is the coordinated sequence …, *R*, t_1 ,t_2, … (preserving any coordination links from the original sequence …, Rt_1t_2, … in the natural way)
- $[\![\ldots, \neg\phi, \ldots]\!]$ = {(…, true, …) | $[\![\Sigma]\!]$ contains (…, false, …)} ∪ {(…, false, …) | $[\![\Sigma]\!]$ contains (…, true, …)}, where Σ is the coordinated sequence …, ϕ, … (preserving any coordination links in the natural way)
- $[\![\ldots, \phi \wedge \psi, \ldots]\!] = \{(\ldots, \text{true}, \ldots) \mid [\![\Sigma]\!] \text{contains} (\ldots, \text{true}, \text{true}, \ldots)\} \cup \{(\ldots, \text{false}, \ldots) \mid [\![\Sigma]\!]$ contains one of (…, true, false, …), (…, false, true, …), or (…, false, false, …)}, where Σ is the coordinated sequence …, ϕ, ψ, . . . (preserving any coordination links in the natural way)
- $[\![\ldots, \forall x\phi, \ldots]\!] = \{(\ldots, \text{true}, \ldots) \mid [\![\Sigma]\!] \text{contains} (\ldots, d, \text{true}, \ldots)$ for every object *d* in the domain *x* ranges over} ∪ {(…, false, …) | $[\![\Sigma]\!]$ contains (…, *d*, false, …) for some object *d* in that domain}, where Σ is the coordinated sequence …, x, $\underline{\phi}$, … (preserving any coordination links from the original sequence …, $\forall x\phi$, … in the natural way, and additionally merging in further links between the new occurrence of *x* and any free occurrences of *x* in ϕ)[32]

Chapter 2 of Fine (2007) turns to giving semantics for languages with names or constants. There Fine aims to apply the fundamental ideas of the account just sketched to examples like our:

(1) `Cicero admired Tully.`
(5) `Cicero admired Cicero.`

and he also proposes a semantic difference between these, even if the expressions `Cicero` and `Tully` would have the same meaning taken individually.[33] An obstacle to this proposal is that whereas variables are associated with *a range* of values, and so we can "coordinate" different variable occurrences by mandating that their ranges vary in lock-step with each other, names take only *a single* semantic value. So we can't use the varying-in-lock-step mechanism to distinguish the semantic value of the pair `Cicero`, `Cicero` from that of the pair `Cicero`, `Tully`. Fine admits that this makes his use of "coordination" to talk about semantically required codesignation for arbitrary expressions a bit awkward (pp. 39ff.).

As a result, the semantics we get in Fine's chapter 2 looks different from the account sketched above. Fine here works with an extension of the familiar structured Russellian account of meaning.[34] The extension is that when an object appears several times in a structured proposition,[35] there is the option of adding a "coordination wire" linking those different appearances.[36] This would enable us to represent the meaning of (5) as an extended, possibly-wired structured proposition where the two appearances of Cicero *are* linked, and the meaning of (1) as a possibly-wired structured proposition where they aren't.[37]

Some comments about this.

- The presence of wires in the meaning semantically encodes that multiple arguments to a (possibly complex) predicate are supplied by the same value. In principle, one might also consider the possibility of semantically encoding that multiple arguments are supplied by *different* values. Soames mentions such an idea in (2012, p. 255) (but see also his n. 14; and Salmon, 2012, p. 409, which offer related but different ideas). This possibility is not pursued in any of the work surveyed here. In the possibly-wired structured propositions Fine is working with, the alternative to a semantic wire explicitly requiring several arguments to be the same is instead just semantic neutrality, not requiring the arguments to be the same but not forbidding it either.
- We need to distinguish the possibly-wired structured proposition where multiple appearances of Cicero are explicitly unlinked, from the coarser, Russellian proposition that *carries no information about* whether those appearances are linked.
- Fine's use of the term "uncoordinated" is not consistent. He most often uses this to mean (i) a possibly-wired structured proposition that explicitly lacks some link (pp. 54–55, 78, 83, 96, 111, and perhaps 69); but other times he uses it to mean (ii) a coarser, Russellian proposition that is silent about what arguments may be linked (pp. 52, 56–59, 77). Fine also calls (i) "negative coordination" (p. 56), and Salmon (2012, n. 40) calls it "withheld coordination."
- Fine doesn't immediately say how to integrate the treatment of names in chapter 2 with a semantics for quantifiers. King (2007) has an account of structured propositions using "wires" to capture which quantifiers bind which argument positions.[38] This is ostensibly

> a different use of wires than Fine is working with, but if Fine chose to say that multiple variable occurrences bound by a single quantifier should always be coordinated, then King's wires could be viewed as a special case of Fine's wires.[39]

When several expression occurrences have a meaning that positively links their designata in the way described here, Fine says that the expressions "strictly corefer," in the sense that it is *semantically required that* they codesignate (see pp. 43, 46–47, 50–51, 59, 123; and his 2010d); and he says also that they "represent their objects *as the same*," which he distinguishes from the mere attribution of identity to those objects (pp. 39–40). Generally, recurrences of a single name like `Cicero` will bear these relations, but that is not necessary nor sufficient for doing so.[40] Fine offers as a "good test" for the presence of these relations considerations like this:

> An object is represented as the same [by several expression occurrences] in a piece of discourse only if no one who understands the discourse can sensibly raise the question of whether it is the same.[41]

Fine doesn't officially introduce any operators or predicates that are truth-conditionally sensitive to the presence of semantic wires of the sort we've described. In fact, he says:

> [T]he coordinative aspect of the coordinated content of a sentence, such as "Cicero wrote about Cicero," is entirely lacking in any special descriptive or truth-conditional character and relates entirely to how its truth-conditions … are to be grasped. (p. 59; contrast ch. 4, nn. 10 and 11)

But one would naturally expect the semantic differences Fine posits between (1) and (5) to contribute in some way[42] to a difference in truth-conditions between attitude reports for which they are the complement clauses:

(1*) `Anita believes that Cicero admired Tully.`
(5*) `Anita believes that Cicero admired Cicero.`

And in chapter 4, Fine does discuss two readings of attitude reports on which (1*) and (5*) may have different truth-conditions. His "weak *de dicto*" reading has coordination among expressions in a report's complement – as in (5*) but not (1*) – iff cyclic thoughts are being attributed (pp. 91, 102ff.). His "strong *de dicto*" reading has an even tighter connection between the expressions in the complement and expressions in the subject's linguistic or mental repertoire. However, Fine acknowledges at several places that he hasn't given, and doesn't know how to give, a compositional semantics for these reports.[43]

One noteworthy feature of the example reports Fine discusses in his chapter 4 is that they sometimes involve coordination across the complements of multiple attitude verbs, perhaps even ones involving different subjects.[44] If we assume that all and only occurrences of the same variables are coordinated in the following, Fine would regard these reports as having different truth-conditions (on some readings):

(19c) `Juan said that` *x* `chased` *y*`, and Anita wondered if` *y* `chased me.`
(19d) `Juan said that` *x* `chased` *y*`, and Anita wondered if` *x* `chased me.`

even when *x* and *y* are assigned the same designation.

A full appreciation and assessment of Fine's views about attitude reports has to consider his account of how the analogue of linguistic coordination occurs in thought, too – what I'm calling cyclic thought-contents. Fine counts it as a strength of his approach that the same fundamental ideas drive the story of both linguistic content and cyclic thoughts. But for several reasons, including limited space, I propose to ignore this part of Fine's story, and to keep our focus on proposals about the semantics of public languages (whether natural or formal). Let's continue on with merely an intuitive grasp of cyclic thoughts. They are the kinds of thoughts that subjects who consider and assent to (5) normally manifest, but subjects in `Paderewski` cases don't. (I discuss these thoughts further in my 2016.)

I've mentioned several key elements in Fine's account that are referenced elsewhere in this chapter. Let's gather and label them:

F1 Officially, Fine doesn't introduce operators or predicates whose truth-conditions are sensitive to coordination in their arguments. But one assumes that a full story about his "weak" and "strong *de dicto*" attitude reports would involve such, presumably by way of a difference in what possibly-wired structured propositions are expressed by different complement clauses (though see note 42 above).

F2 There are natural reasons for Fine to say, as he seems disposed to say, that multiple variable occurrences bound by a single quantifier are always coordinated.

F3 On some (readings of) attitude reports, expressions in their complement are coordinated iff they attribute cyclic thoughts. I'll only be referring elsewhere to the left-to-right half of this claim.[45]

F4 Fine allows coordination across the complements of multiple attitude verbs (even ones with different subjects). Recall that Richard also aimed to achieve this, by saying we sometimes only quantify over correlations at the discourse level.

I've proposed already to ignore one central element to Fine's thinking, namely:

- his specific account of cyclic thoughts.

I will also pass over the connections Fine draws between semantic wires and semantic requirements (see the citations a page ago), as well as:

- how he connects these wires to ideas about what's "transparent" to a competent language-user, or his epistemology of language use more generally (pp. 49, 60–65). I'm sympathetic to many of Fine's claims about what's "semantically required," but would resist treating knowledge of such requirements as necessary conditions for competence or understanding.[46]

In a moment, I'll identify a third element in Fine's thinking that I'll also be ignoring. And in §7 below, I'll demonstrate a language that (*contra* point F1 above) does have predicates whose application is sensitive to semantic wires among their arguments.

Fine developed his account further in his (2010d), and in responses to his critics.[47]

Fine presents his account as a form of "Referentialism" or "Millianism" (pp. 5, 37, 45, 53), and contrasts it to Fregean accounts (pp. 35–37, 42, 58–60). Some of his commentators challenge this, and suggest his account may be closer to Fregeanism than it is to familiar

forms of Millianism (see also Richard's, 1990, pp. 147–154 comparison of his own view to Fregeanism). The taxonomic question here isn't especially interesting in itself.

More pressing is another complaint voiced by several critics, namely that Fine's account doesn't seem to offer any way to semantically distinguish:

(1) `Cicero admired Tully.`
(22) `Tully admired Cicero.`

or:

(23a) `Cicero was an orator.`
(23b) `Tully was an orator.`[48]

If these sentences occur as *part of a larger discourse containing other occurrences* of the names `Cicero` or `Tully`, then Fine's account as developed so far *does* distinguish discourses containing (1) from ones containing (22), and similarly (23a) from (23b) (see Fine pp. 52–53). But what if the sentences *aren't* part of such larger discourses (see Soames, 2010, p. 470; 2012, pp. 245, 250)? There is considerable pre-theoretic pressure to still see some semantic difference between (1) and (22), and reluctance to allow our story about how (1) relates to (22) to fundamentally differ from our story about how it relates to (5). Of course, standard Millians already deny there is any semantic difference between (1), (22), and (5). But they've built up a collection of explanatory tools to make those denials more palatable. Fine's account may have encouraged us to think we wouldn't need those tools; and if he after all needs to resort to them to accommodate intuitions about (1)/(22) and (23a/b), this may undermine some of the motivation he offered for the extra semantic machinery. This is a complaint Soames voices several times (in his 2010, pp. 473–474; 2012, pp. 234, 237–238, 262–263; see also his 1994, pp. 132–133).

One point Fine can make in reply is that his account would at least distinguish *embeddings* of (1) and (22) in attitude reports, on his "strong *de dicto*" reading of those reports. Admittedly, we're only offered a skeletal story about how that reading works. In Fine (2010b) he develops a more ambitious response, which involves coordination of expression occurrences in utterances of (1) not only to discourses in which it's *actually* contained, but also to all discourses in which it *might possibly* be contained.[49] If one gets over the extravagant multiplying of meanings it requires, this move offers powerful armament to Fine: it enables him to treat isolated utterances of (1)/(22) or (23a/b) in the same way he's already prepared to treat discourses containing them and other occurrences of `Cicero` or `Tully`. I worry if the armament may be *too* powerful, and no longer sufficiently explanatorily disciplined. Pinillos (2015, pp. 327–330) presses other worries. But I won't try to sort these worries out. Instead, I'll just declare:

- this ambitious appeal to merely possible discourses

to be another element of Fine's thinking that I'll mostly ignore. I will point out, though, that similar proposals are made by Taschek (see notes 48 and 49 above), and in different ways by Richard (the "third level" of his 1986–1987) and even Pinillos.[50]

My own reaction to the complaints about (1)/(22) and (23a/b) is to acknowledge that the novel semantic structure that Fine and/or Richard advocate may not be a cure-all for every challenge to Millianism. There may be sufficient reason to admit it nonetheless.

I won't attempt a systematic overview of other complaints that have been raised against Fine's account. But the papers by Soames cited in note 47 above deserve special mention, for two reasons. First, many of the complaints in these papers overlap ones in Soames (1987b), demonstrating shared challenges faced by Fine and by Richard. Second, some of Soames's complaints that we haven't yet discussed can be usefully framed against the way I've expositied Fine's account here.

One assumption behind some of Soames's arguments (such as 1987b, p. 113) is that attitude verbs will be truth-conditionally sensitive *at most* to coordination patterns local to their own complements. Bracketing the question of Soames's *entitlement* to that assumption (in 1987, before his opponents' views were elaborated), I observe that it is one that Richard and Fine resist: see move F4 and note 42 above. Admittedly, Fine does not give us any compositional semantics where this assumption is withheld. Such a semantics *can* be given (at least, if we suppress Fine's qualms about semantics being too "typographic," and also help ourselves to the machinery of "dynamic semantics"). But I won't have the space to give it here. Our discussion in §7 below will also fail to vindicate the ambitions behind F4.

Another assumption behind some of Soames's arguments (1987b, pp. 116–117; 1994, pp. 130ff.; 2010, pp. 473–474; 2012, pp. 243–244, 247–249, 250–251) is that attitude verbs on his opponents' accounts *will be* truth-conditionally sensitive to coordination patterns in their complements. That is, he assumes claim F3 above. But in fact, the full account offered by Fine permits attitude verbs to sometimes (on their "pure *de re*" reading) ignore those patterns. (We'll discuss this further in §6 below; see also the `value` operator I'll introduce in §7. As mentioned in note 43 above, Soames complains about this aspect of Fine's account. His discussion raises serious challenges that I won't attempt here to address.)

5

There are many differences in detail and in declared motivation between Richard and Fine.

One difference I'll point out is their approach to cyclic thoughts. Richard simply assumes we think with Mentalese sentences, and handles such puzzles accordingly. In Pryor (2016), I sort-of follow him, though at a greater level of abstraction: I appeal to the graph-theoretic structure of a subject's attitudes, rather than to any *concrete linguistic implementation* of that structure. Fine by contrast wants an explanation at the level of the *semantic content* of our thoughts, and so has to expand our conception of that content. Essentially, he can be understood as advocating that we count graph-theoretically distinctive relations among our attitudes as hitherto unacknowledged aspects of content. As I said before, Fine also wants his picture of the content of thought to be unified with his semantics for natural language.

Another difference is that Richard's account of the semantic differences between simple sentences like (1) and (5) – namely, they express different English-annotated RAMs – isn't "relational" in Fine's sense, but is instead of a kind that Fine will reject as too "typographic." Its advantage is that it enables Richard (unlike Fine, see point F1 above) to give a compositional (albeit context-sensitive) semantics for attitude reports. Given current technology, it's not clear how to offer such a semantics without provoking Fine's qualms about being too "typographic," or encumbered with conventional artifacts.

Despite these differences, there is also a good deal of shared ambition and predictions between Richard's and Fine's accounts. Fundamentally, both aim to explain how (1) and (5) can differ semantically, even when it's stipulated that `Cicero` and `Tully` don't differ in respects relevant to the content of isolated unembedded sentences like (23ab), where they

occur singly. When it comes to attitude reports, Richard can join Fine in denying that it's anything "intrinsic" to the content of the complement that constrains what thought is being attributed (Richard, 1990, p. 135) – though they develop this denial in different ways. Finally, the overlap in Soames's criticisms of them (mentioned at the end of the previous section) attests to the similar dialectical terrain they occupy.

In addition to the threads in Kaplan and Geach identified in note 14, other work that anticipates Fine's proposals – and does so especially closely – is Taschek (1992; 1995; 1998). I've already mentioned some points of contact in notes 44, 48, and 49; another is their shared rejection of a Compositionality Principle that tracks only the semantic contributions expressions make when they occur singly. An important respect in which Taschek diverges from Fine is that he takes the difference between (1) and (5) to merely be one of "logical potential," not to be part of their "information content."[51]

There is a range of other work since the late 1980s that has points of contact with Richard's and Fine's accounts. The other authors cannot be understood to defend a common position or thesis, but in each case there is some clear affinity with the Putnamian idea that guided Richard and Fine.

Some of this other work focuses on cyclic thoughts. For example, Campbell (1987–1988) talks of an inference "presuming" or "trading on" identity, without the subject needing any *identity judgment* or premise. Lawlor (2002) talks of "anaphoric thinking." See also Perry (1980)'s discussion of "internal identity," and work in the "mental files" tradition like Recanati (1993; 2012, esp. chs 8–9; 2013, esp. §4 which replies to Goodsell, 2013; and Recanati, 2015, §I).[52]

Other work does focus on *de jure* codesignation in language; however, some of the authors deny that the phenomenon makes a *semantic* difference. See for example the work by Schroeter cited in note 41. Taylor (2003b; 2015) contrasts "explicit" versus "coincidental" codesignation, and says that the former is "syntactically or structurally" marked. These differ in what they "manifest" or "display," and in their "dialectical significance," but not in their contributions to propositional content (see esp. Taylor 2003b, §§2 and 8; 2015, pp. 257–259). As explained above, Taschek (1992) and Richard (1986–1987) also hesitate to make such differences be semantically encoded.

Unlike them, Pinillos (2011; 2015) *does* claim that the phenomenon he's exploring makes a semantic difference. He uses the phrase "*de jure* coreference," meaning by it something narrower than I express with "*de jure* codesignation," since he says bound variables don't refer and so never corefer (2011, pp. 318–320, but see also his n. 10). But the underlying semantic mechanism Pinillos is studying is one he thinks *does* apply to bound variables, and to empty names (2011, pp. 317–318; 2015, pp. 324–325), as well as to ordinary names and to anaphoric but unbound pronouns, like `his` in the "strict" reading of (4a). Pinillos calls this mechanism "p-linking" (2011, pp. 317ff.). Though his terminology may suggest otherwise, Fine also wants his notion of "semantically required" or "strict" coreference to apply to bound variables and to empty names (see notes 39 and 35 above). One fundamental difference between Fine and Pinillos is that the former takes his phenomenon to be an equivalence relation, at least when we confine ourselves to intrapersonal cases (Fine, 2007, pp. 55–56, but see note 44 above). It is central to Pinillos's account, on the other hand, that the underlying semantic mechanism can be intransitive and non-Euclidean even in that domain. He gives examples like the following:

(24) `As a matter of fact, the orator Cicero is my brother Marcus; you will get to meet the great Marcus Tullius Cicero tonight.`

Pinillos would claim that the first and third name occurrences, and also the second and third, are p-linked, but the first and second are not.[53]

Pinillos states several "axioms" governing the behavior of p-linking. Some of these govern the relation between it and coreference, or between it and variable binding (Pinillos endorses a claim like F2 from §4 above). Most interesting is his Axiom 2 (2011, p. 318), which Pinillos understands to have something like F3 as a consequence. This is closely related to Pinillos's Principle of Attitude Closure, which he takes to be partly criterial for the phenomena he's exploring. This Principle says that when the complement of a belief report exemplifies *de jure* coreference, that report will entail a corresponding report using the complement's existential generalization. For example:

(5*) Anita believes that Cicero admired Cicero.

will entail:

(10*) Anita believes that someone admired himself.

Pinillos says this Principle may hold for more attitudes than just belief, though not for every attitude.

We'll discuss F3 and Pinillos's Attitude Closure in more detail in the next section.

Pinillos's other criteria for the phenomena he's exploring are principles that are reminiscent of Fine's claims about the epistemology of language use. Pinillos says that anyone who fully understands a sentence exemplifying *de jure* coreference will be in a position to infer its existential generalization, for example, from (5) to:

(10) Someone admired himself.

or from (3d) to:

(25) Terentia betrayed someone who was unhappy.

Pinillos says also that anyone who fully understands a sentence exemplifying *de jure* coreference will know of the relevant expressions that if they both manage to designate, they designate the same thing.[54]

My own stance towards these "criteria" is very guarded. Because I have different background views about the epistemology of language use than Fine and Pinillos – which dispute seems like it should be orthogonal to the issues we're exploring – I'm inclined to doubt that any linguistic properties meet the epistemic tests they propose. Perhaps refined and more qualified versions of these tests will prove more acceptable. But even in advance of knowing what those will look like, I do still find myself sympathetic to the possibility of a genuine semantic phenomenon in the neighborhood they're exploring. So my preference is to detach the epistemic criteria from the semantic proposals.

Goodsell (2014) shares some of my qualms about the epistemic commitments of Pinillos's criteria. She also complains that these criteria wouldn't be able to characterize *de jure* codesignation across multiple speakers or in non-declarative constructions (p. 298); also that, as Pinillos states them, the criteria don't sufficiently respect the fact that one can understand a belief report without oneself, or the report's subject, knowing that all its constituent expressions refer (pp. 304–305).

Finally, I'll note that Fiengo and May (2006) has similar motivation and points of contact with Richard's and Fine's views. But it also differs in complex ways that I can't explore here. (Additionally, Fiengo and May embrace some of the controversial views about the epistemology of language that I prefer to separate from the semantic proposals we're considering.)

6

Claim F3 and Pinillos's Attitude Closure have come up several times in our discussion. The status of these claims is contested.

Suppose Diego has a long dream in which, contrary to fact, he's married. Inside the dream, he often finds himself waking to the sight of scattered socks, and supposes this may have been done by a mouse. Being terrified of mice, he begins a nightly campaign to wake his more fearless wife so she can catch the sock-mover. But they never encounter a mouse. Finally, it emerges that Diego and his wife have all along been moving the socks themselves, while sleepwalking. Thus ends Diego's dream. Diego, now awake for real, reports his dreamt campaign with bemusement:

(26) `All along, I was hoping my wife and I would catch ourselves!`

The pronoun `ourselves` gets its reference from `my wife and I`, so these expressions should be *de jure* codesignative. But then the acceptability of the report would conflict with any claim like F3. In the scenario described, it was *not* the case that Diego all along bore a hopeful attitude that represented the chasers and the agents chased as one, and from whose aim he could infer `Someone catches themself`.

This example also puts pressure against Salmon's and Soames's views, summarized in §1 above. The fact that Diego has no real wife suggests that `my wife and I` occurs inside the report's complement, as it appears to, rather than taking wide scope. (The reflexive morphology of `ourselves` also suggests this.) So on a bound-variable analysis of referential dependency, the report has the form:

(26′) `All along I was hoping: (λx. x would catch x) (my wife and I)`

And on Salmon's and Soames's accounts, any such report would *also* attribute a hope that represents the chasers and the agents chased as one.

Soames several times appeals to similar examples, with the form:

(27a) `Juan told Maria that he wasn't Juan/that man/him.`[55]

In all its variations, this is an acceptable report of a scenario where Juan attempted to mislead Maria about his identity: that is, he said to her something like `I am not Juan`, or `Juan is shorter than me`. Another of Soames's examples has the form:

(27b) `Each man told Maria that he wasn't that man.`[56]

Soames assumes that the singular terms in the complements of (27ab) should each be *de jure* codesignative with the subject of the report. Presumably, they will then be *de jure*

codesignative with each other; and if F3 is in place, they'll report Maria to have been told something from which she could infer `Someone is not himself` – contrary to Soames's description of the scenarios.[57]

Spelling this out more carefully, the assumptions that raise trouble are that:

(i) if two expressions are *de jure* codesignative with a third, they are also *de jure* codesignative with each other

(ii) if the expressions in the complement of (27ab) are codesignative with each other, those reports characterize Maria as having been told contents from which she could infer `Someone is not himself`. This is the claim I earlier labeled F3.

Some advocates of *de jure* codesignation deny that (ii/F3) always holds: see for example Recanati (2012, §9.2) and Goodsell (2014, pp. 302–304). Fine himself only endorses F3 for some readings of attitude reports.

Pinillos acknowledges examples like (27ab) (2011, pp. 315–316 and n. 41). Instead of rejecting (ii/F3), he prefers to reject assumption (i). He denies that *de jure* coreference (or p-linking) is an equivalence relation; so the singular terms in these reports' complements needn't be p-linked with each other, after all.

Like Pinillos, Soames also sees these examples as demonstrating a failure of Euclideaness and/or transitivity. He thinks we should see the referential dependencies in (27b) and some versions of (27a) as having the form:

(27c) `_____ told Maria that he wasn't that man.`

This contrasts with other examples where referential dependencies have the form:

(28a) `Cicero expected that he would eventually admire himself.`

In (28a), `himself` can't be directly referentially dependent on `Cicero`, since if it were, it could not have reflexive morphology:

(28b) `Cicero expected that Terentia would eventually admire *himself/him.`

The main difference between Soames and Pinillos is that only the latter says these referential dependencies will always be semantically encoded. As I explained in §1 above, Soames thinks the dependencies show up in the semantics iff they're generated by variable binding. That will only partially overlap with Pinillos's ambitions for the notion of *de jure* codesignation.

Higginbotham and Heim also argued for a distinction in dependency patterns like (27c) versus (28a). Their examples have an advantage over Soames's, in that his case for denying `that man` is dependent on `he` in (27ab) turns on assumptions like (ii/F3) above (or, on his own view, on (Z2) and (Z3) from §1). Since the status of these assumptions is unclear, demonstrations that don't need them are more forceful.

Heim (1998, examples 26a–g and 27a–d) gives contrasts like these:

(29a) `Every student claimed that he called his mother before the teacher did.`

(29b) `Every student claimed that he called his mother before the teacher did.`

On Heim's view, the referential dependencies exhibited in (29a) invite the "strict" reading, where it's the teacher's calling *the students*' mothers that is being discussed. The referential dependencies in (29b) invite the "sloppy" reading, where it's the teacher's calling *the teacher's own* mother that is being discussed.

Higginbotham (1985, examples 68–74) gives contrasts like these:

(30a) `They told each other they would succeed.`

(30b) `They told each other they would succeed.`

On his view,[58] the referential dependencies exhibited in (30a) describe scenarios where the subjects said to each other `I will succeed` or `We will succeed.` The referential dependencies in (30b) describe a scenario where they said `You will succeed`, as is also unambiguously reported by:

(30c) `They told each other to succeed.`

However, though Heim and Higginbotham argue that these dependency patterns should be distinguished, they do not argue for their being semantically encoded. So far as I can see, their discussions just cited could be developed along the lines of either the Salmon/Soames stance from §1 above, or the Richard/Fine/Pinillos stance. (The former will have been more familiar to Heim and Higginbotham.)

7

We can get further insight into the Richard/Fine/Pinillos proposals by considering some ideas from computer programming. One obstacle to this is that many readers will have little fluency with the kind of programming we need. But we can work around that. Those readers who are acquainted with programming may be thinking of it on the model of a sequence of instructions. That is the "imperatival" model of computation. But there are other models, too, such as the "declarative" or "functional" model. The existence of this model of computation may be less familiar, but *what it understands computation as* is closer to ideas that philosophers and linguists are well-acquainted with, like formulas of predicate logic. On the declarative model, arithmetic expressions like $2 + 7 \leq 9$, $2 + 7$, and 2 all count as programs, which evaluate to true, 9, and 2, respectively. The set of inequalities $\{2 + x \leq 9, x > 5\}$ might be a program that evaluates to a set of assignments binding x to 6 or 7. The regular expression `/ima[a-z]*ng/` might be a program that evaluates to the set of English words {`imaging`, `imagining`}. And so on. There's nothing in either of these models of computation that prevents it from expressing or achieving all that the other can; their styles of doing so will just tend to be different. We'll work with the declarative model.

If readers have ever encountered a formal semantics for a programming language (from either of the models of computing just described, or another), it's likely to be of the form computer scientists call "operational semantics." This will have surface resemblance to a

proof theory, or a system of rules for rewriting the program text. (Those analogies have defects, but that's not important for our purposes here.) But there are other forms of semantics for programming languages. The one most similar to what philosophers and linguists think of as semantics is called "denotational semantics." If you've ever seen a denotational semantics for even a simple (yet Turing complete) programming language, you will have been struck by how much more mathematically sophisticated it is than anything appealed to in natural language semantics.

All of this – associating "programming" with the imperatival model of computation, thinking of formal semantics for programming languages in operational rather than denotational terms, and the sophistication of actual denotational semantics – can encourage the impression that the semantics of programming languages is profoundly different from, and will teach us little about, what we understand as semantics for languages like English (or Esperanto, or arithmetic).

However, I invite you to consider some notions from declarative programming that I will structure as a series of extensions to (a decidable fragment of) arithmetic. I will present these in a way that aims to maximize their familiarity. I won't present a formal semantics for these notions here. The extensions to arithmetic that one sees in a full-blown declarative programming language fall into "lightweight," "middleweight," and "heavyweight" categories. The "lightweight" additions don't require anything fundamentally new for their semantics. The "middleweight" additions do; but no more radically new than philosophers and linguists are already familiar with from Lewis (1979) and discussions of "dynamic semantics." The "heavyweight" additions include things like unlimited recursion, and giving a denotational semantics for these does require sophisticated techniques. But none of what we'll be doing here needs to make use of those notions. We can limit ourselves only to "lightweight" and a few "middleweight" additions.

Let's begin with restricted quantification, with which I assume familiarity. Throughout I'll use *x*, *y*, … as variables ranging over the domain ℕ. Later I'll use *xs*, *ys*, … as variables ranging over lists of ℕ, and *f*, *g*, … as variables ranging over functions of one or two arguments (usually mapping ℕs to ℕs, but sometimes with other types).

The sentences:

(31a) $\forall x < 7 \left(2 + x \leq 9\right)$

(31b) $\forall x = 7 \left(2 + x \leq 9\right)$

express truths, given the standard interpretations of <, ≤, =, +, and the numerical constants. We'll represent that by writing:

(31b) $\forall x = 7 \left(2 + x \leq 9\right) \quad \Rightarrow \quad$ true

Our ⇒ notation also permits us to state what values sub-sentential expressions have, on the assumed interpretation. For example:

(32a) $2 + 7 \quad \Rightarrow \quad 9$

and:

(32b) $2 + x \quad \Rightarrow \quad 9$

on an assignment that binds variable *x* to the value 7.

An interesting difference between (31a) and (31b) is that the latter uses a restrictor that we know in advance is satisfied by exactly one value in the relevant domain. It will be useful to introduce a special syntax for this case:

(31c) `let` $x = 7$ $(2 + x \leq 9)$ ⇒ true

A natural extension of this syntax permits us to partially specify our assignments in the case of sub-sentential expressions, too, like (32b):

(32c) `let` $x = 7$ $(2 + x)$ ⇒ 9

We can specify assignments more fully by embedding uses of `let`:

(33a) `let` $x = 3$ (`let` $y = 4$ $(2 + x + y)$) ⇒ 9

which we might abbreviate as:

(33b) `let` $x = 3, y = 4$ $(2 + x + y)$ ⇒ 9

Now let's see how to express the same things using the syntax of the programming language Scheme.[59] This is how you write $2 + x + y$ in Scheme:

(34)
```
(+ 2 x y)
```

and this is how you write the equivalent of (33ab):

(33c)
```
(let ([x 3][y 4])
     (+ 2 x y))
```
⇒ 9

For later comparison, it will be helpful to note that just as you can say $\forall x\, \exists x\, (x = 9)$ in predicate logic, and inside the parentheses only the innermost effect on the binding of x will be operative, so too can you say:

(35a)
```
(let ([x 0][y 0])
     (let ([x 3][y 4])
          (+ 2 x y)))
```
⇒ 9

How this is described in programming circles is that the innermost `let` introduces new local bindings for x and y that "shadow" their more global bindings. These local bindings are in place only until the parenthesis that closes the innermost `let` expression.

(35b)
```
(let ([x 0][y 0])
     ((let ([x 3][y 4])+) 2 x y))
```
⇒ 2

What happened here is that the local bindings to x and y were in place only for the interpretation of the symbol + (where they made no difference). When we evaluate the operands of +, we use the more global bindings for x and y.

The Scheme programming model countenances several types of simple and compound values. Simple values include things like numbers, truth-values, and various functions; we won't concern ourselves with other simple values. Compound values include things like lists of other values; we won't concern ourselves with other compound values. In Scheme, a list can contain a variety of values, such as numbers, truth-values, and yet other (embedded) lists. But we will mostly work with homogeneous lists of numbers. Here is one way to build a list in Scheme:

```
(36a)  (list 2 3 4)                          ⇒  (2 3 4)
(36b)  (let ([x 3] [y 4])
           (list 2 x y))                     ⇒  (2 3 4)
```

The syntax of Scheme includes *keywords* like `let`; simple expressions including *symbols* like `+`, *x*, and *y*, and *literals* like the numerical constants and `true` and `false`; and compound expressions which are lists of other expressions. Scheme *evaluates* symbols to the values those symbols are bound to, at that position and stage in the program. It evaluates literals to themselves. It evaluates lists of expressions by evaluating the head of the list, and if the result is a function, applying it to the argument values that the rest of the list evaluates to. (If the head of the list doesn't evaluate to a function, the list is not evaluable.) Lists beginning with keywords are evaluated in special ways.

Here are some more operations on lists. Note that here we bind a variable to a list rather than to a simple value. I'll follow the convention of using plural variable names like *xs* for this.

```
(37a)  (let ([xs (list 2 3 4)])
           (head xs))                        ⇒      2
(37b)  (let ([xs (list 2 3 4)])
           (tail xs))                        ⇒    (3 4)
(37c)  (cons 2 (list 3 4))                   ⇒  (2 3 4)
```

The `cons` function is so-named because it *cons*tructs a list, from a specified head element and rest of the list. This should now make sense:

```
(38)   (let ([xs (list 2 3 4)])
            [ys (cons 1 (tail xs))])
           ys)                               ⇒  (1 3 4)
```

The symbol `+` comes pre-bound to the standard addition function. Scheme also lets you build custom functions, like so:

```
(39)   (λ (x y) (+ 2 x y))
```

This evaluates to a function that accepts two arguments which it then adds to 2, and returns the result. (Scheme doesn't have any canonical way to display this function, so I have omitted the ⇒.) We can apply that function to values like so:

```
(40a)  ((λ (x y) (+ 2 x y)) 3 4)             ⇒  9
```

This behaves the same as (33c). We can also bind variables to functions that we build in this way:

```
(40b)  (let ([g (λ (x y) (+ 2 x y))])
            (g 3 4))                                  ⇒  9
(40c)  (let ([g (λ (x y) (+ 2 x y))]
             [x 3])
            (g x 4))                                  ⇒  9
```

λ-expressions can contain variables that are bound outside of them (variables that are "locally free"):

```
(41)   (let ([y 4]
             [f (λ (x) (+ 2 x y))])
            (list (f 3) (f 13)))                      ⇒  (9 19)
```

These free variables are understood in what programmers call the "lexical" rather than the "dynamic" style. That is:

```
(42)   (let ([y 4]
             [f (λ (x) (+ 2 x y))]
             [y 0])
            (list y (f 3) (f 13) y))                  ⇒  (0 9 19 0)
```

The innermost binding of *y* to 0 affects the interpretation of that variable in the final list expression; however, it doesn't affect the interpretation of *y* inside the definition of the applied function *f*. The other understanding, where the result of the above would be (0 5 15 0), is also coherent; but it's not what Scheme uses here.

Contrast (42) to:

```
(43)   (let ([y 4]
             [f (λ (x) (let ([y 0]) (+ 2 x y)))])
            (list y (f 3) (f 13) y))                  ⇒  (4 5 15 4)
```

Here the more local binding for *y* is inside the definition of *f*, so it *does* affect the results we get when applying *f*; also, that binding is in effect only *inside* the definition of *f*, so it *doesn't* affect the interpretation of *y* in the final list expression.

This finishes our introduction to (the core of) the "purely declarative" part of Scheme. The ideas exhibited here all fall under the heading of what I called "lightweight" additions to arithmetic. Next we move on to some "middleweight" additions.

Lists of the sort we've worked with so far are *static* values. Once built, such a value never changes. In this respect they are just like numbers and truth-values. However, Scheme also has a notion of a *mutable* list, which can at different stages of its existence contain different elements. We can build and mutate such a list like this:

```
(44)   (let ([xs (mlist 2 3 4)]
             [_ (set-head! xs 1)])
            xs)                                       ⇒  (1 3 4)
```

A few comments about this. First, note the different syntax: `mlist` rather than `list`. Second, this example contrasts with (38) where we bound *ys* to a version of *xs* with a new head, but *xs* itself would still have evaluated to the list (2 3 4). Third, the usefulness of `set-head!` is in the *side-effect* you get from applying it, not from its return value. In most Schemes, `set-head!` doesn't return anything useful, so we assign its return value to the "throwaway" variable _. Fourth, in introducing such values and operations into the language, we've abandoned what programmers call "referential transparency." This loosely coincides with what philosophers mean by that phrase. Consider:

```
(45)  (let ([f (let ([ys (mlist 0)])
                 (λ (x) (let ([y  (head ys)]
                              [_ (set-head! ys (+ 1 y))])
                          (+ 2 x y))))])
        (list (f 3) (f 3) (f 3)))                          ⇒ (5 6 7)
```

If you reason through the evaluation of this expression, you'll see that at each application of *f* to the constant argument 3, we end up adding a different head-value from the changing list *ys*. So the result of applying *f* is not determined by the values supplied to it as arguments.[60]

Scheme also has some built-in functions that return truth-values as their result. For example:

```
(46a) (let ([y 4])
        (equal? y 3))                                      ⇒ false
(46b) (let ([ys (list 2 3 4)])
        (equal? ys (list 1 3 4)))                          ⇒ false
```

Instead of `equal?` we could also have written `egal?`. With non-mutable values, there is no difference between these. But with mutable lists, we face a choice. Two variables might be bound to distinct mutable lists, which happen currently to contain the same elements. A mutation to one of the lists would not in itself have any effect on the other list. Should we count such lists as equal, since they now contain the same elements? Or should we say that they're unequal, since they are distinct, independently mutable containers? Scheme handles this by saying such lists are `equal?` but not `egal?`. Thus:

```
(47)  (let ([xs (mlist 2 3 4)]
            [ys (cons 1 (tail xs))]
            [zs xs]
            [_ (set-head! xs 1)])
        (list zs (egal? xs zs) (egal? xs ys) (equal? xs ys)))
                                                   ⇒ ((1 3 4) true false true)
```

We've been working with the notion of a mutable list *value*. But so far, our understanding of how *variables* work has stayed the same. Once a variable is bound to a value, it stays so bound. That binding may perhaps be "shadowed" by a more local use of the same variable symbol, but it continues to exist and will again be visible after the syntactic scope of the more local expression expires. But in fact, Scheme also has a notion of *mutable variable bindings*. It allows us to say:

```
(48)  (let ([y 4]
            [f (λ (x) (let ([_ (set! y 0)]) (+ 2 x y)))])
           (list y (f 3) (f 13) y))                    ⇒  (4 5 15 0)
```

Contrast (43), where the final element in the result was 4. Here we don't "shadow" the outermost binding of *y* with a new binding. Instead we *mutate* that very outermost binding. The result is that even *outside* the definition of *f*, after *f* has been applied, that new mutated binding will still be visible.

One of the reasons I chose Scheme for these examples is that it has *both* mutable values *and* mutable variable bindings. It's most common for programming languages to have only one of these. Here is an example of using both notions in Scheme:

```
(49)  (let ([xs (mlist 2 3 4)]
            [zs xs)
            [_(set-head! xs 1)]
            [_(set! xs (list 0 0 0))])
           (list xs zs))                               ⇒  ((0 0 0) (1 3 4))
```

In (47), we used the variable *xs* to mutate the *single list value* that both *xs* and *zs* were bound to; then when we evaluated *zs,* this change was visible. The same is true in (49); but after mutating that list value, we next mutate the *variable xs* to become bound to a new list. *zs* still stays bound to the old list.

At this point, the imaginative reader who's read the rest of this chapter will wonder whether there might be a way to make variables be even more intimately related than *xs* and *zs* were in the above examples: to not merely happen at one stage in the program to designate or be bound to the same value, but to be made *de jure* codesignative, even through mutations of either variable's binding.

The answer is that yes, this is possible, but it requires going beyond the most familiar features of Scheme.[61]

Consider:

```
(50)  (let ([xs (list 2 3 4)]
            [zs xs])
           (alias ([ws xs])
                  (let ([_ (set! xs (list 0 0 0))])
                       (list xs ws zs))))              ⇒  ((0 0 0) (0 0 0) (2 3 4))
```

Here, as before *zs* is merely `egal?` to *xs*, so when we mutate the binding of the latter, the former still says bound to the original list. However, we have used the new keyword `alias` to make *ws* be so intimately related to *xs* that changes to the binding of either of them also affect the other. Aside from the `set!` operation, none of the other language features we've seen (so far) differentiate between `alias` and `let`.

We can also introduce an operation that works like λ, except that it accepts only variables as operands, and it associates the parameters in its definition with those operands using `alias` rather than `let`:

```
(51)  (let ([f (aliasλ (ws) (let ([_ (set! ws (list 0 0 0))])
                              ws))]
            [xs (list 2 3 4)])
           (list xs (f xs) xs))                    ⇒ ((2 3 4) (0 0 0) (0 0 0))
```

Because of how the parameter *ws* internal to the definition of *f* gets associated with the variable *xs* when we evaluate (`f xs`), mutating *ws*'s binding also ends up mutating the variable *xs*.

With these resources in hand, we can define a third kind of equality predicate:

```
(52)  (let ([aliased? (aliasλ (u v)
                              (let ([u0 u]
                                    [_ (set! u (mlist 0))]
                                    [result (egal? u v)]
                                    [_ (set! u u0)])
                                result))]
            [x 3]
            [z x])
           (alias ([w x])
                  (list (egal? z x) (aliased? z x)
                        (aliased? x x) (aliased? w x))))
                                                   ⇒  (true false true true)
```

This makes use of the expression (`mlist 0`), which creates a new mutable list. Such a value is guaranteed to not be `egal?` to any other value that variables are already bound to. What this definition of `aliased?` does is save the original value of its parameter *u* as u_0, then mutate the binding of parameter *u* and see whether the other parameter *v* ends up being `egal?` to the new value. It saves the result of that test as *result*, then restores *u* to its original value (in case the invoking context needed it), and returns *result*.

This `aliased?` predicate is like *f* in example (45), in that its result is not determined merely by the argument values passed to it (*z*, *x*, and *w* all have the same value, 3). But `aliased?` is more interesting, in that it *does* track whether its operands stand in the *de jure* codesignating relation that different occurrences of *x* (in the same binding context) stand in to each other, and that *w* and *x* also stand in. Thus the last two tests in the final list expression evaluate to true; whereas *z* on the other hand is merely `egal?` to *x*, not also `aliased?`

Defining `aliased?` in the way just demonstrated makes essential use of `(mlist 0)` and `set!`, which involve the two kinds of mutation we explained above. This is a good way to get an intuitive handle on how such a predicate could even be possible. But it may give the impression that in less "dynamic" languages, that don't have any of these mutation novelties, a notion like `aliased?` would be inexpressible. To counter that impression, I'll report that it's possible to define `aliased?` in many implementations of Scheme in a way that doesn't make use of mutable values or bindings. The mechanisms required to do this are complex; see the URL in note 59 for details. Regardless of how feasible it is to implement `aliased?` in these specific programming languages, it could always be given a semantics as a native programming idiom even without the language also having mutable values and bindings. (But the strategies for giving a formal semantics for these several notions will be similar.)

It should be possible to use `aliased?`, `alias`, and `aliasλ` all together. We demonstrated how the first and second should work together in (52). Here is how they should interact with the third:

```
(53)  (let ([x 3]
            [g (aliasλ (u v)
                       (list (aliased? u u) (aliased? u v)
                             (aliased? u x)))]
            [z x])
           (alias ([w x])
                  (list (g x x) (g w x) (g z x))))
                       ⇒    ((true true true) (true true true) (true false false))
```

Because *w* and *x* are aliased, and passing them to *g* aliases them to *g*'s internal parameters, all of the tests in *g* come out true when any combination of *w* and *x* are supplied as operands. But *z* merely happens to currently be bound to the same value as the other variables. It isn't `aliased?` to them. (Of course, *z* is `aliased?` to itself.)

The predicate `aliased?` is not (or not merely) a quotative operator, as it doesn't just test for whether its operands are syntactically matching. Rather, it's sensitive to the patterns of *de jure* codesignation in those operands. It provides an example of the kind of predicate that we observed Richard offering (and Fine at least gesturing at). (But it doesn't have the interesting behavior I labeled F4 in §4 above.) These authors think a linguistic context like `Anita believes that _____ admires _____` may evaluate to true when `Cicero` and `Cicero` are supplied as operands, but false when `Cicero` and `Tully` are supplied – even if those names themselves have the same semantic value. In the same way, (`aliased? x x`) may be true but (`aliased? x z`) false, despite *x* and *z* being bound to the same value.

Here is another connection to our earlier discussion. In the following:

```
(54)  (let ([value (λ (y) y)]
            [x 0])
           (list (aliased? x x) (aliased? x (value x))))
                                                    ⇒    (true false)
```

we define an operation `value` that extracts the value that *x* is currently bound to, returning it in a form that doesn't count as `aliased?` to *x* (or any other variable). We might then think of contexts like `Juan told Maria that _____ wasn't _____` as being false when the *de jure* codesignative expression-occurrences `he` and `him` are supplied as operands, but as being true when `he` and (`value him`) are supplied (see note 57). Perhaps the key to understanding Soames's (27a) is to interpolate such an (unpronounced) operation. (This is similar to Fine's strategy of positing a special *de re* reading of the report, and vulnerable to some of the same objections.)

If one is new to the programming idioms explained here, what we've walked through may seem exotic and to shed little light on the intelligibility or prospects of predicates with `aliased?`-like behavior in natural language. However, as I said at the start of this section, there is little in the "lightweight" additions that one should find semantically novel. And of the "middleweight" additions, we made use of mutable values and variables only as a stepping-stone to get to an understanding of how `aliased?` and its partners work. In principle, as I said, we don't need to define them with mutation. They can exist in languages that are mutation-free.

As I acknowledged earlier, programming languages can and often do make use of genuinely exotic ideas that require more sophisticated semantic techniques than readers of this chapter may be familiar with. But none of those ideas – unlimited recursion, continuations, fancy types – are needed to make sense of `aliased?` and its friends.

I hope this section contributes towards "domesticating" the kind of predicates that fans of *de jure* codesignation are friendly to, that is, making them seem less alien and somewhat less "magical." As we've seen, such predicates are needed anyway for some formal languages, ones that ought not seem miles away from natural language. In my view, the work summarized in this chapter's earlier sections creates a case for exploring whether this kind of semantic structure is present in natural language too: perhaps in ways that encode a semantic difference between demonstrative and the "strict" anaphoric uses of pronouns from §1, or perhaps in ways that affect the truth-conditions of attitude reports, or perhaps in ways that encode the different patterns of anaphora posited by Heim and Higginbotham in §6 for unembedded sentences.[62]

Notes

1 Compare Higginbotham (1985, examples 62–63); Heim (1998, pp. 213–216, 241); and McKay (1991, p. 718). On the contrast between merely intended coreference and the referential dependence we see in examples that follow, see Evans (1980, §5), Recanati (2012, §8.1), and Fiengo and May (1994, esp. pp. 3–13, 49–51). Goodsell (2014) articulates a notion of "assumed coreference," also distinguished from the relations exemplified below.

2 When talking about this example, I'll rely on the reader to understand that the sentence is being used and understood in the way described; and similarly for later examples. Of course, the *displayed sentence* might also be used in the earlier way. It will simplify exposition for me to presume (*contra* Lasnik, Bach, and some other authors discussed below) that the demonstrative and anaphoric uses of pronouns are syntactically different.

3 For a survey of some accounts, see Dahl (1973). The "bound-variable" analysis described below is proposed in Keenan (1971), Williams (1977), Reinhart (1983, ch. 7), and elsewhere. For convenience, I will apply the labels "sloppy" and "strict" also to the hypothesized disambiguations of sentences like (3e).

4 This is sometimes denied, for instance by Recanati (2005, p. 308) and Salmon (1986b, pp. 50–52), though Salmon (1992, pp. 59, 65) allows that (3b) may be ambiguous. The "strict" reading is attested by Dahl (1973, p. 84) and Evans (1977, p. 95), who also cites Dummett and Partee. See Partee (1989, n. 4). The "strict" reading will dominate if we replace `Atticus` with a female name like `Terentia`. In that case, it's controversial whether the "sloppy" reflexive reading would be available at all.

   Sometimes it's suggested that `Cicero mourned his own daughter` gives us a way to force the "sloppy" reading. But McKay (1991, n. 21) convincingly shows that "strict" readings are still possible with such sentences. See also Reinhart (1983, ch. 7, n. 13).

5 Bach is in one way less radical than Lasnik, as he allows that expressions like `himself` and `his own` may have the distinctive syntax and/or semantics that other theorists attribute to our (3) examples more broadly. In another way, Bach is more radical, as he argues that pronouns apparently bound by quantifier phrases should be understood on the model of (2ab), too. See also Recanati (2005).

6 Compare Tomioka (1999, examples 7 and 8, and n. 4; also examples 23, 24, 27). For further discussion, see Soames (1989–1990, pp. 211–212), McKay (1991, pp. 721–723 and n. 30), Salmon (1992, pp. 65–66; 2006a), and Soames (1994, pp. 120ff.).

7 See Salmon (1986b; 1992; 1989, pp. 216ff.; 2006b; 2010, pp. 447–449); Soames (1985, n. 12; 1987a, n. 24 and pp. 58–61; 1987b, esp. §8; 1989–1990, pp. 204ff.). Salmon counts the propositional

forms in (Z2) as "logically equivalent" (2010, p. 451; also 1986b, pp. 51–55 and n. 23), but not synonymous, and he denies that ($\lambda x.$ *x* admired *x*) *a* will always be *inferable* in the sense we're considering from the others.

At (2010, pp. 453–454, 456–457), Salmon discusses whether we should count λ-conversions as synonymy-preserving when the bound formula is monadic.

Other endorsements of parts of the stance I attribute to Salmon and Soames include Kaplan (1986, pp. 269–271), Higginbotham (1991, pp. 360–361), and McKay (1991). See also note 3 above; and Bach (1987, pp. 256–257), though the rest of Bach's chapters 11–12 argues against extending the view beyond pronouns like `himself`. Salmon also cites Wiggins (1976b, pp. 164–166; 1976a, pp. 230–231).

8 This is meant to suggest the image of their structure somehow looping back on itself. Compare the idiom `(cons #1=expr #1#)` in some implementations of the programming language Scheme, which can be used to specify cyclic data structures.

Some authors already call these "reflexive" contents – but we've used that term above in other senses: for the reflexive morphology of `himself`, and for the "sloppy" reflexive readings of some of our examples. Salmon and Soames would also use the term for bound predicates with the structure of (3b′), and for our present notion. But since it's controversial how much these different phenomena coincide, it's conceptually more hygienic to introduce a new label here. (There is also the mathematician's notion of a "reflexive relation," which is not directly relevant to what we're discussing.)

Fine calls cyclic contents "coordinated," but I suspect this term is too closely associated with his own views. (And Fine also uses the term to refer to a kind of linguistic structure, as well as a kind of content.)

9 Fine says only a few words about anaphoric pronouns (see note 33 below), but the bound-variable analysis does not seem to constitute his understanding of them. It's clear that it doesn't constitute his understanding of (5) (see Fine, 2007, pp. 69–70). It's not clear whether Fine regards (3b) and (5) as semantically equivalent. Soames (2010; 2012) interprets him as giving them different contents, albeit contents the understanding of which requires recognizing that it's true iff the other is. As explained above, Soames's own view is that (3b) does have the form (3b′), and (5) does not, and neither is (3b′) inferable from the content of (5). But on his view, standardly someone who utters (5) will *also thereby assert* the content (3b′) (see Soames, 1987b, §8; 2002, esp. chs 3 and 8; 2005). See also Richard (1990, pp. 216–217).

Soames proposes treating the "strict" readings of anaphoric (3) sentences semantically on a par with the (2) examples (1989–1990, pp. 210–211). See also Heim and Kratzer (1998, pp. 240–241).

10 See Pinillos (2011, example 18). I'm ignoring accounts of (11a) in terms of focal alternatives. On some variations of the account sketched here, the first conjunct of (11bc) would be presupposed rather than asserted. Similar examples could be given using `Even Cicero ...` or `It was Cicero who ...`

11 See Heim and Kratzer (1998, §9.3) for an introductory overview.

12 Compare Evans (1980, examples 49, 53, 55) and Heim (1998, examples 13, 20).

13 Church (1954) accepts this consequence, and argues that the doubt really available to these subjects is not about lawyers but rather about the *predicates* `lawyer` and `attorney`. But Church did not think attitudes were *in general* about linguistic expressions.

14 Kaplan's views were presented in unpublished lectures delivered in 1985 (reported in Soames, 1987b, p. 112 and n. 19; and Salmon, 1986a, p. 164), and also in a few lines in Kaplan (1990, n. 6). There are also passages where Kaplan embraces the competing Salmon and Soames view: see note 7 above.

Geach's views are complex. One challenge is that he denies that sentences always have a single "subject-predicate analysis" (even in the absence of syntactic ambiguity; see Geach, 1962/1980, §§24, 27; 1975b, pp. 144–146). At the same time, he claims that some pairs of sentences are "logically equivalent," "say the same thing," or "have the same import," and yet "contain different predicables" or "predicate different things" of their respective subjects (1962/1980, §§78, 80). It's

hard to know how we are to identify *the* predicate of a sentence in some of these cases. In some places, though, Geach explicitly affirms that sentences like (5) predicate the same thing of Cicero that `Atticus admired Atticus` (and `Atticus admired himself`) predicate of Atticus (1962/1980, §26; 1965, p. 112; 1975b, pp. 139–140, 141, 147). Given Geach's analysis of reflexive pronouns (1962/1980, §§80–84), this means he'd see them all as "containing" the predicate $\lambda x.\ x$ admired x. In other cases, though, he denies that recurring names induce this predicate structure. For example, `Only Satan pities Satan` differs in meaning from (the "sloppy" reading of) `Only Satan pities himself` (1962/1980, §80). Geach does acknowledge a "strict" reading of the similar sentence `Not only Socrates loves his wife`, but although he allows that it's "logically equivalent" to `Not only Socrates loves Socrates's wife`, this is one of the cases where he says the paired sentences have different analyses (1975a, pp. 197–198). He interprets the former as "containing" the predicate $\lambda y.$ not only y ($\lambda x.\ x$ loves y's wife), as also proposed by Evans (1977, pp. 95–97); whereas the latter has $\lambda y.$ not only y ($\lambda x.\ x$ loves Socrates's wife).

15 Richard's diagnosis was that (16a), despite its counter-intuitiveness in his scenario, is as true as (16b). But in later work he retracted this.

16 Pryor (2016) proposes that *graph-theoretic* constructions are a good way to abstract the shared core of these proposals. See also Strawson (1974/2004, pp. 45–46).

17 Compare Carnap's account of reports summarized at the start of §2 above. Salmon in fact worked with *guises* rather than Mentalese sentences; and he called the doxizing relation "BEL."

18 For example, Jacob (1991, pp. 93ff.).

19 See Fodor (1990a, esp. pp. 71–73), and Fitch (1984; 1986; 1987, ch. 4). Fitch (1996) defends a more specific view, of the sort associated below with Schiffer.

20 The following complaints are taken from Schiffer (1987, pp. 459–461; 1992; 1994, pp. 285–287; 1995, §5; 2000; 2003, pp. 39–46; 2008). Schiffer's own preferred theory is given in (1994; 2003, esp. ch. 2).

21 See Crimmins and Perry (1989), Crimmins (1992b; 1995b). Crimmins (1995c, pp. 200–201) objects to calling his view a "hidden indexical" theory.

22 Or what plays its role on their account: Crimmins thinks of T as a "thought map" describing a hypothetical attitude in terms of particular mental representations ("notions") the subject is assumed to have (1992b, chs 4–5).

23 In the hands of Stanley and Recanati, that phrase later acquired a more specific meaning than Perry understood by it (see Perry, 2001/2012, pp. 55–57; Korta and Perry, 2011, ch. 9; Crimmins, 1992b, pp. 16–17, 152).

24 The term "quasi-singular" comes from (Schiffer, 1978, p. 182). Recanati holds that in some cases complements don't express those but rather express content schemas (1993, ch. 18, n. 15 and §19.4), and in other cases express general propositions (§19.3).

Recanati's vocabulary and theoretical framework make his views somewhat hard to track. In (1993, ch. 3; 1995, §3) he distinguishes an utterance's "semantic" from its "truth-conditional" content. He understands the latter to be a Russellian proposition, and identifies it with "the proposition expressed" or "what is said" by a literal utterance (1993, pp. 54–55, 65). That is the notion that best fits our inquiry. (His "semantic" content belongs to more ambitious stories about how to explain successful understanding; see the discussion of Loar's stockbroker at Recanati, 1993, pp. 53ff.; 1995, pp. 184–185.) Recanati's view of unembedded sentences with "referential" terms is that their utterances have singular truth-conditional contents, as Russellians claim (though their semantic content will be richer). What I report in the text is that Recanati thinks *these terms* also have Russellian truth-conditional contents when embedded, but *the complement clauses that contain them*, as wholes, usually have richer, quasi-singular truth-conditional content (see 1993, pp. 395–397; 1995, pp. 188–190). In this regard, Recanati is closer to Schiffer's preferred (2003) view than to the HIT that Schiffer discusses more critically. Schiffer compares his version of HIT to Recanati's in Schiffer (2000).

25 Richard's theory is developed in (1990, chs 3–4), the central parts of which were also published as his (1989). The theory was then refined in his (1993; 1995; 1997, §§10–11; 2006; 2013b).

26 This quote is from Richard (2013b, p. 12). At this level of abstraction, Richard's view also resembles the neo-Fregean account of attitude reports offered in Forbes (1990). But I won't explore those connections.

27 So Richard's view has similarities and connections to the "ILF" theories advanced in Higginbotham (1986; 1991), Segal (1989), Larson and Ludlow (1993), Larson and Segal (1995, ch. 11), and Ludlow (2000).

28 Richard uses "accepts" in a technical sense: see his (1990, §1.5, and pp. 181–183, 211–213). He generalizes to attitudes other than belief in (ch. 3, n. 20).

29 Note that Richard never prohibited correlations from being many-one; he always allowed diverse expressions in a complement to correctly report beliefs that a subject in fact has by doxizing recurring Mentalese expressions. That is, if Anita accepts only (her Mentalese version of) (5), nonetheless (in some contexts) I can correctly say:

(1*) `Anita believes that Cicero admired Tully.`

That is, (in some contexts) (1*) can *allow* the reported thought to be cyclic. Richard doesn't think such a report would *attribute* a cyclic thought (1990, p. 217), but he left open whether it's *ever* possible for diverse terms in a complement to do so (pp. 214–217). In other words, he only endorsed the left-to-right direction of: recurring expressions in the complement → the report attributes a cyclic thought.

The cases that later caused Richard to partly withdraw that endorsement were given by Soames and Crimmins. We'll discuss them in §6 below.

30 Fine resists Putnam's specific proposal that sentences like (1) and (5) differ in "logical structure" (p. 41). But they are pursuing similar ideas.

31 My presentation isn't maximally explicit either: for conciseness, I help myself to some natural shorthands that I'll trust the reader to understand.

For further discussion of the "antinomy of the variable" and Fine's solution, see Kellenberg (2010) and Pickel and Rabern (2016). Compare the latter's solution to https://en.wikipedia.org/wiki/De_Bruijn_index (accessed 30 September, 2016), which is a more efficient technique commonly used in writing compilers.

32 One may have the concern that the natural extension of the given semantics to $\supset$ will conflate $[\![\forall x(Fx \supset \bot)]\!]$ with $[\![(\forall xFx) \supset \bot]\!]$. But this does not happen. Although both of those will depend on $[\![x, F, x, \bot]\!]$, they'll depend on it in different ways, and end up being non-equivalent as they should.

33 Soames (2010, p. 465) suggests that Fine should handle examples like `I asked Martha to call me` along the same lines as (5). At (pp. 41, 122–123), Fine considers handling anaphoric examples like (3d) in this way too. See Soames (2012, pp. 259ff.) for complaints about how this interacts with Fine's desire to have multiple readings of attitude reports.

34 King (1996; 1995) is paradigmatic of these. This tradition goes back to Lewis (1970) and Cresswell and von Stechow (1982), and has roots in Carnap's notion of "intensional isomorphism," discussed in §2 above. See also the later developments of King's view, and comparisons to other accounts of structured propositions, in King (2007; 2011).

As Fine remarks on his p. 54, he only needs to rely on enough structure to talk about the different appearances of some object in a proposition.

35 Fine also briefly addresses the possibility of handling empty names and "confused" names (see ch.2, nn. 4 and 14, pp. 126–127; and his 2010c).

36 See (pp. 54–57; also pp. 77–78). For other articulations of this idea, see Soames (1987b, p. 112, attributing it to unpublished work by Kaplan), Salmon (1986a, ch. 4, n. 4; 1992, pp. 59–60), and Pinillos (2011, pp. 319ff.). Higginbotham (1985, pp. 564ff.) uses a similar device, but his explanatory purposes are not the same.

An alternative to wires would be to tag all the leaves of a structured proposition with indices, understanding leaves to be linked when they have the same value and index.

Fine in fact defines his "coordination schemes" so as to allow wires spanning *multiple* structured propositions in a sequence.

37 On (p. 59), Fine might instead be read as saying that (1) expresses a coarser, Russellian proposition; but I will ignore that possibility because it ill fits the overall shape of his account. Further, this passage appears only a page after Fine introduces the idea of different "levels" of semantic value. (Recall we saw a similar idea in Richard, 1986–1987.) Our discussion here is focused on only the most specific level.

38 See King (2007, pp. 41–42, 218–222); he is following a suggestion made by Quine (1940/1981), and then repeated in Kaplan (1986, p. 244), Salmon (1986a, p. 156), and Soames (1989–1990, p. 204). See also Crimmins (1992b, ch. 4) and Evans (1977, pp. 88–96). (On p. 102, Evans permits the wires to cross sentence boundaries, and from pp. 104ff. they're also used to join "donkey pronouns" to their antecedents. In these cases the apparatus has to be interpreted differently.)

This appeal to wires shouldn't be *conflated with* the way they're appealed to in the work cited in note 36 above. It is a substantive question whether the present use can be a special case of the wires Fine is working with. Nor should either of these uses be conflated with the use of arrows in linguistic work on anaphora (for example, in Higginbotham, 1983; 1985; Moltmann, 2006, pp. 236ff.; Heim, 1998; McKay, 1991, pp. 724ff.; and the usage in Evans, 1977, from 102ff. mentioned above; see also Fiengo and May 1994's notion of "coindexing without c-command"). But as we'll see in §6 below, there are plausible connections between these.

39 That does seem to be Fine's thinking (see his p. 30 and n. 11, and pp. 115–117). See also Soames (2012, pp. 238–241). Recall also Richard's notion of "co-relativized" terms, mentioned in §3 above.

40 For the failure of necessity, see note 33 above. See also Fine's discussion of `Carl/Peter Hempel` at pp. 46–47. `Paderewski` cases might be counter-examples to sufficiency, though this turns on controversial issues. Compare Fine's example where one has stipulated the same definition for `glub` and `flox` but isn't explicitly aware of having done so (pp. 129–130). For a range of similar cases, see the works cited at Soames (2012, n. 5).

41 This quote is from (p. 40); see also (pp. 60ff.). As we'll see in the next section, Pinillos uses similar language when defining his notion of "*de jure* coreference." So too does Recanati: see his (2012, pp. 92, 106, 110). Schroeter uses similar language when defining the notion of expressions "*striking one* as being *de jure* coreferential": in her (2003, pp. 18ff.; 2007, pp. 600, 611; and 2008, pp. 110ff.), she talks of its being "obvious and rationally incontrovertible" to the subject that the expressions codesignate. In (2012) she adds the condition that this appearance be "epistemically basic." Unlike some of the others, Schroeter thinks the appearance of *de jure* coreference can be mistaken: see her (2007; 2008).

42 I say "in some way" because Fine rejects the common view that `believe` expresses a dyadic relation between a subject and the proposition expressed by its complement (see his discussion of (SB) at 2010b, pp. 476–478; also the move labeled F4 below).

43 See (pp. 93, 120–121, and his 2010b). Notably, what Fine says about the truth-conditions for the "strong *de dicto*" reading involves reference to the report itself, but he doesn't want to say that the *semantic content* of these reports is self-reflexive. The issue raised next in the text (and afterwards labeled F4) also poses difficulties.

Fine also posits a "pure *de re*" reading of attitude reports that ignores any coordination in its complement. See Soames (2012, appendix) for complaints about these ambiguities, and how they interact with the motivation and explanation Fine offers in the earlier parts of his book.

44 Though with multiple subjects, we confront special issues because Fine denies that interpersonal coordination will be transitive: see Fine's (pp. 98, 105ff.), also Taschek (1998, §5) and Richard (1990, pp. 210ff.; 1993, 129ff.). Crimmins (1992a, pp. 193–194; 1995a, pp. 387–390) criticizes this part of Richard's account. Taylor (2000, pp. 175ff.; 2003b, pp. 12ff.) also discusses such cases, but instead of abandoning transitivity, he denies that subjects are authoritative about whether they've introduced a new name.

45 As we saw in §3 above, Richard committed to the left-to-right direction of this. See also Pinillos's Principle of Attitude Closure, discussed below, also his (2011, p. 316); Taschek's "Logic Requirement" in his (1995, pp. 77, 81, and 86; 1998); and Soames's "Belief Coordination Principle" in his (2012). See also Taylor (2003b, §8) and Forbes (1987, pp. 24–25).

46 Compare the discussion of "transparency" in Recanati (2012, chs 10–11; and 2015, §I.iii, which replies to Ball, 2015); Schroeter (2007; 2008); and the discussion of "slow-switching" in Boghossian (1989; 1992; 1994; 2011; 2015) and many other sources surveyed in Parent (2013, §3.3). See also Salmon's discussion of recognizing the reappearance of an object in several propositions, in his (2012, pp. 423–424, 425–426, and 427ff.; 2015, pp. 455–456). Salmon argues that failures of such recognition aren't manifestations of linguistic incompetence or semantic ignorance.

We'll return to this issue with Pinillos, in the next section.

47 For discussion of Fine's work, and his replies, see Soames (2010), Lawlor (2010), Hovda (2010), and Fine (2010b; 2010c; 2010a). See also Soames (2012) and (1987b, whose relevance was mentioned at the end of §3 above); and Salmon (2012), Fine (2013), Salmon (2015). Further commentary includes Ostertag (2009), Rattan (2010), Sosa (2010), Bonardi (2013), Weiss (2014), and Pickel and Rabern (forthcoming).

48 See Salmon (1986a, ch. 4, n. 4), Ostertag (2009, p. 348), Sosa (2010, pp. 353, 356), Soames (1987b, pp. 112–113, 123; 2010, p. 467; 2012, pp. 237, 244–245), Salmon and Soames (1988, p. 13, n. 10), and Pinillos (2015, p. 326). Putnam (1954, p. 156) seems to embrace the semantic equivalence of (23a) and (23b).

Taschek acknowledges this problem for his own account, which anticipates Fine's in several ways: see his (1995, pp. 78–80; 1998, p. 327). He proposes a solution much like the "ambitious" one I go on to describe Fine giving.

49 See also Taschek (1995, pp. 81ff.; 1998, esp. §II).

50 Pinillos (2015, pp. 330–334) argues that if we attend to embeddings of (1)/(22) and (23a/b) in attitude reports, they will be "always accompanied, often implicitly," by other reports that are also asserted or (more likely) *presupposed* in the discourse. This is similar to the proposal I mentioned Richard offering. The view of reports that Pinillos ends up with is similar to the Crimmins and Perry view described in §3 above, albeit with presuppositions taking over some of the work of their "unarticulated constituents."

51 This term is from his (1992). In (1995), he defines a somewhat different notion of "Content," in terms of which (1) and (5) do count as different because they aren't inter-substitutable in attitude reports. This notion is more closely connected to Taschek's notion of "logical potential" than to his notion of "information content," which he stops using.

52 Pryor (2016) discusses connections between this work and the "multi-centered" views of content in Ninan (2012; 2013). See also Recanati (2012, §18.3; 2015, §I.iv).

53 See his (2011, p. 315; 2015, p. 325). Sometimes Pinillos gives examples using "slash names" like `Hesperus/Phosphorus`. Other times he uses anaphoric expressions like `there` or `that planet`. Pinillos's interpretation of all these cases is challenged by Goodsell (2014) and Contim (2016).

54 Compare Fine's quote about "sensibly raising the question" whether the things they designate are the same. Contim (2016) argues that this criterion of Pinillos's may be too liberal.

55 See Soames (1989–1990, example 15a; 1994, examples 8ab; 2010, example 26; 2012, example 34a). See also Higginbotham (1991, examples 38 and 45), Sider (1995, pp. 503–505), Crimmins (1992a, pp. 192, 195–196; 1995a, pp. 383–387, 391–392), and Cumming (2008, example KR).

56 See Soames (1994, example 34d; 2012, example 34b). See also Higginbotham (1991, examples 42 and 46).

57 A special twist on Soames's examples is when they're embedded inside other reports, for example `The children thought that Juan told Maria that he wasn't him`. See Soames (1989–1990, example 18; 1994, example 9). For the purpose of reporting the children's thinking about Juan, we'd want `he` and `him` to be *de jure* coreferential; but for the purpose of reporting the content of what Maria was allegedly told, we wouldn't.

Using the machinery from §7 below, the children's thought might be represented as: `((λ (he) (alias ([him he]) (disclaim-identity he Maria he (value him)))) Juan)`, where `disclaim-identity` represents its second operand as having been told something from which she could infer `Someone is not himself` iff the third and fourth operands are `aliased?`, as here they are not. Nonetheless, from the perspective of the embedding thought, `he` and `him` are `aliased?`.

58 In an earlier paper Higginbotham (1983, pp. 404–406) endorsed the idea that "referential linking" is transitive. But Higginbotham (1985, pp. 570–574) argues against this.

59 This is one of three main families of contemporary language that descend from Lisp. Scheme is a *family* of languages because it has many different "implementations" that extend or further specify the language in somewhat different ways. Details on how to run the example code supplied here inside some implementations of Scheme can be found at http://www.jimpryor.net/research/code/dejure.html (accessed September 30, 2016). The linebreaks, indentation, and variation between `()`s and `[]`s are all just stylistic choices.

60 I've assumed that in the evaluation of `(list (f 3) (f 3) (f 3))`, we evaluate the operands from left to right. If we proceeded in a different order, we'd get a different result. Different implementations of Scheme handle this differently.

61 What we will make use of are ideas that in other programming languages go by the keywords "same lvalue," and "call-" or "pass-by-reference." Everything exhibited below is expressible in (many implementations of) Scheme, using that language's ability to define *macros* that operate on program syntax before it gets evaluated. See the URL in note 59 above for details.

Glossary

Absolute versus relative identity: The contrast between absolute and relative identity has its home in the debate over Peter Geach's Relative Identity Thesis, given in "Identity," *Review of Metaphysics*, 21 (1967). An absolute-identity relation is an equivalence relation which satisfies Leibniz's Law; a relative-identity relation is an equivalence relation which does not. It is uncontroversial that some relations are mere relative-identity relations. In fact, of course, this is true of all equivalence relations not satisfying Leibniz's Law (q.v.). What is controversial is whether an equivalence relation expressible in the form '*x* is the same A as *y*,' where 'A' is a sortal term, can be a mere relative-identity relation, and whether absolute identity is expressible at all. Geach answers the first of these questions affirmatively and the second negatively.

Absolute versus relative notions of necessity/possibility: When 'necessity' and 'possibility' are qualified by prefixing 'physical', 'natural', 'biological' or the like, the notions expressed are probably best understood as relative to the assumption of the laws of the discipline to which the adjective alludes. To say, for example, that it is physically necessary that *P* is to claim that, given the laws of physics, it must be true that *P* (i.e., that it is a logical consequence of the laws of physics that *P*). Similarly, the claim that it is physically possible that *P* would normally be understood as the claim that the laws of physics do not exclude its being true that *P* (i.e., that it is logically consistent with the laws of physics that *P*). If, as is plausible, we allow that the universe might have behaved according to different physical laws, so that what is physically necessary, as things are, might not have been true, our notion of physical necessity could be said to be merely relative. Sometimes, however, when we claim that it is necessary that *P*, we mean to deny that there is any possibility of things being otherwise – we are claiming absolute necessity. Such an absolute notion is probably intended in claims about logical or metaphysical necessity. In terms of possible worlds, it is absolutely necessary that *P* if *P* holds true at all possible worlds without qualification; whereas it suffices for it to be physically necessary

A Companion to the Philosophy of Language, Second Edition. Edited by Bob Hale, Crispin Wright, and Alexander Miller.

that *P* that *P* holds true at all physically possible worlds (i.e., all possible worlds where the actual physical laws hold), and similarly for other relative kinds of necessity.

Abstract objects: The distinction between abstract and concrete entities is usually thought to be exhaustive and mutually exclusive. A popular view is that the hallmark of the concrete is existence in physical space and/or time. As a corollary of this, it is often held that abstract entities lack causal powers and are consequently incapable of entering into causal relations with other things (though this threatens to make our knowledge of them problematic). In opposition to this way of characterizing the abstract/concrete divide, others have been proposed: for instance, some philosophers characterize abstract entities as ones which depend logically for their existence upon the existence of certain other entities (as, for example, a smile is said to depend for its existence upon the face whose smile it is), while others characterize abstract entities as the products of some sort of mental or logical process of 'abstraction' from concepts (as when numbers and geometrical shapes are said to be such products).

Acquisition argument: Common term for an objection (associated particularly with Michael Dummett) to any semantic theory which allows the nature of speakers' private states (see **Privacy**) to influence the meaning of the words they use: it cannot explain how a learner ever acquires an understanding of the language. The argument turns on the point that the meanings to be learned would depend on the nature of the private states of the already-competent speaker, something which cannot, by definition, be known to anyone else. The Acquisition Argument is a close relation of the arguments from Communicability (q.v.) and Manifestation (q.v.). (See Chapter 11, MEANING AND PRIVACY.) Interest in these arguments has been aroused by Dummett's suggestion that they support an 'anti-realist' approach to semantics, shifting emphasis away from the conditions under which a sentence is true, perhaps Evidence-transcendently (q.v.), towards those under which a speaker might properly assert it. (See also Chapter 20, REALISM AND ITS OPPOSITIONS.)

Analyses, reductive and reciprocal: An analysis of a concept breaks up a given concept (the analysandum concept) into its component concepts (the analysans concepts). An analysis is represented by a biconditional, thus (in the case of meaning): X means that p iff … [favored analysans concepts]. Analyses are usually taken to be reductive in nature, which is to say that the analysans concepts are held to be more fundamental or basic (in some sense to be specified) than the analysandum concept. But analyses may also be reciprocal in nature, meaning that the concepts on either side of the biconditional are seen as on a par – the idea being that whilst the proposed analysis is non-reductive, it illuminates the concepts involved by drawing out important links between them.

Asymmetric Dependence Theory (ADT): ADT is a development of the intuitive idea that the truth-conditions of a thought are resilient with respect to other causes of the thought. According to ADT, a Mentalese (q.v.) predicate C refers to the property P if C locks onto P (J. Fodor, *Psychosemantics*, MIT Press, 1987; *A Theory of Content*, MIT Press, 1990). C locks onto P just in case (i) it is a law that Ps cause Cs, (ii) there is some Q other than P such that Qs cause Cs, and for any Q distinct from P, if Qs cause Cs then the causal connection between Qs and Cs depends on the Ps-cause-Cs law, but not the other way round. In other words, if Qs failed to cause Cs it would still be the case that Ps caused Cs; but if Ps failed to cause Cs then Qs wouldn't cause them either. ADT solves the Disjunction problem (q.v.), since not all the causes of C constitute its reference. However, the theory is difficult to evaluate, since it is not clear exactly what the dependence relation between laws (or causal relations) is, and whether it is naturalistic.

Binding: In semantic and syntactic theory, 'binding' refers to the relation between an anaphoric item (pronouns, reciprocals, and other pro-forms) and its antecedent such that the former is referentially dependent on the latter. Modern inquiry into binding goes back at least to the 1960s, but is often summarized by so-called *classic binding theory* (CBT) formulated in the early 1980s by Noam Chomsky. CBT contains three principles:

(A) Reflexives (*herself*, *themselves*, etc.) are bound by a local antecedent.
(B) Pronouns (when bound) are bound by a non-local antecedent.
(C) Referential terms (e.g., names, bare plurals, etc.) are not bound (free).

The precise characterization of locality is a long-standing matter of dispute, but it is traditionally understood to be a syntactic relation of hierarchical distance relative to certain categories (intuitively, one might think of *local* as meaning *at least local to the clause*; so, (A) says that a reflexive must be bound by an item within the same clause as it). One item (a binder) binds another (the bindee), if they share an index and are in the right syntactic configuration in adherence to the stated principles. The content of the three principles are exemplified below:

(1) a Sam_i thought Dave_j liked $\text{himself}_{*i/j}$ [Only *Dave* is local enough to bind *himself*]
b Sam_i thought Dave_j liked $\text{him}_{i/*j}$ [Only *Sam* is non-local enough to bind *him*]
c He_i thought she_j liked $\text{Jo}_{*i/*j}$ [Referential *Jo* lacks any antecedent]

The linguistic status of binding is currently unsettled; whether, that is, it is a syntactic, semantic, or pragmatic phenomenon, or some admixture of the three. Many of these uncertainties go back to the 1970s, and gain a new urgency by various scruples against the free use of indexes within the so-called *minimalist program*, as well as the development of alternative syntactic accounts that reject the fundamental role of configurational or merely syntactic conditions on binding.

Whatever the ultimate fate of binding, the notion is not to be confused with co-reference, which is an extra-linguistic relation. For example, (2) is acceptable on the indicated reading, but is a Principle C violation:

(2) Only Bill_i likes Bill_i

(2) does not so much refute Principle C as indicate an obviation of the principle; after all, that the two tokens of *Bill* in (2) refer to the one individual is not a matter of linguistic competence. Moreover, binding applies to bound-variable anaphora, involving quantifier phrases, where the antecedent is not referential, and so the relation of binding cannot be one of mere co-reference. Thus, if co-referential items are inter-substitutable *salva veritate* (in the relevant contexts), then substituting referential terms for pronouns will result in (at worst) Principle C violations:

(3) a Bill_i thought he_i was a genius
b Bill_i thought Bill_i was a genius

Such substitution produces a change of meaning (truth-conditions) where the binding is bound-variable anaphora:

(4) a $\text{Every philosopher}_i$ thinks he_i is a genius
b $\text{Every philosopher}_i$ thinks every philosopher_i is a genius

CBT is designed to cover both overt and covert items within a syntactic structure. Thus, binding is appealed to as a diagnostic for covert items. For example, according

to Principle A, a reflexive requires a local binder, but a reflexive may occur in the absence of any such *overt* binder:

(5) Mary wanted to leave by herself/*himself

The difference in the indicated judgments in (5) suggests that the non-finite clause has a covert subject (commonly designated PRO) that is both referentially dependent on *Mary* and binds *herself*, but cannot bind *himself* without an agreement error arising. If (5) (apparently) occurs as a complement of an embedded question, no potential for an agreement error arises:

(6) Sam wondered who Mary wanted to leave by herself/himself

This is explained by the covert subject of the non-finite clause being a covert trace or copy of *who*, which, being unmarked for gender, may bind either reflexive. In effect, therefore, (5) does not occur in (6) as a syntactic constituent, for the respective underlying forms diverge with respect to their constituent covert items.

That binding holds across both overt and covert items has been held to militate for certain syntactic/semantic accounts of philosophically contentious constructions, such as quantifier domain restriction and predicates of personal taste.

Bivalence: The principle of bivalence asserts that every statement is true or false. It should be distinguished from the Law of Excluded Middle, according to which every instance of the schema 'P or not-P' is true. Under the assumption that any false statement's negation is true, bivalence entails Excluded Middle. But Excluded Middle does not entail bivalence, since many-valued and supervaluational semantics may validate the former but do not validate the latter (see **Law of Excluded Middle**). Unrestricted endorsement of bivalence has been taken, especially by Michael Dummett, as the hallmark of a realist position with regard to statements of some given kind. On some views about vagueness, bivalence fails for vague statements, which are held to be neither true nor false in borderline cases.

Causal theory of reference: A causal theory of reference is a theory that attempts to explain the nature of the relation between the use of a referring expression and the referent – to say what it is about the use of an expression in virtue of which it has the referent that it has. What all such theories have in common is the thesis that the reference relation should be explained in terms of a causal or explanatory connection between the object that is the referent and the speaker's use of the expression: the referent of a name, as used on a particular occasion, is that object which plays a certain role in the causal process that results in the speaker's use of the name on that occasion. The constructive task of such a theory is to say more specifically how an object must be causally related to the use of the expression in order to be the referent of the expression.

Character, meaning, and content: The terms 'meaning' and 'content' are used in many ways in philosophy, and it is always important to check what a particular author may have in mind. In the usage of Chapter 38, THE SEMANTICS AND PRAGMATICS OF INDEXICALS, meanings are properties of types of expressions, fixed by the rules of language; contents are properties of specific utterances. In the case of indexicals and expressions containing indexicals, the content of an utterance will not be fully determined by the meaning of the expressions used, but will also depend on context. "Character" is often used instead of "meaning," following David Kaplan in his work on demonstratives.

Cognitive command: The cognitive-command constraint is proposed by Crispin Wright as one of several features or marks in virtue of which realism concerning the subject-matter of a given discourse whose characteristic statements qualify for at least Minimal truth (q.v.) may be maintained. Roughly, a discourse satisfies this constraint just in case it is *a priori* that differences of opinion arising within it can be satisfactorily explained only in terms of something worth describing as a cognitive shortcoming in one or other of the disagreed parties – at least one of the parties to the disagreement is lacking relevant information, or her assessment of the data is distorted by prejudice or idiosyncratic standards, or some such. The intended contrast is with cases in which disagreement may persist after all the relevant information is in, say because the disagreed parties diverge in their affective (non-cognitive) reactions to the facts – as is plausibly the case with divergent judgments about what is beautiful or funny, for example. (See also **Euthyphro contrast, Wide cosmological role**.)

Coherence: Coherence theories of truth hold that the truth of a belief consists in its coherence with the main body of our beliefs; coherence theories of knowledge hold that a belief's justification (but not necessarily its truth) consists in the same coherence. Those who hold these theories vary over what they understand by "coherence." Usually it is agreed that a coherent system must be consistent, and the differences are over what further requirements there are; though clearly they must be determined by the main body of our beliefs. Breadth, together with some sort of overall simplicity, are often required. What these requirements amount to depends on the role assigned to experience. Some hold that the coherent system must fit (in some manner hard to specify) with the content of experience as presented preconceptually. Some hold that experience can bear on the coherent system only by providing us with experiential beliefs, but that these beliefs have a special status: their truth (or their justification) is direct, not a matter of coherence, though to all other beliefs the coherence theory applies. Some, again, hold that their truth (or their justification) does consist in coherence: perhaps the most consistent line for a coherence theorist.

Communicability argument: Common term for an objection (associated particularly with Michael Dummett) to any semantic theory which allows the nature of speakers' private states (see **Privacy**) to influence the meaning of the words they use: it cannot explain how there can be communication between speaker and hearer. For if the former's meaning depends on the nature of their private states, what they mean is (by the definition of a private state, see **Privacy**) unknowable to the hearer. Yet for communication to take place the hearer must know what the speaker means. The Communicability Argument is a close relation of the arguments from Acquisition (q.v.) and Manifestation (q.v.). (See Chapter 11, MEANING AND PRIVACY.) Interest in these arguments has been aroused by Dummett's suggestion that they support an 'anti-realist' approach to semantics, shifting emphasis away from the conditions under which a sentence is true – perhaps Evidence-transcendently (q.v.) – towards those under which a speaker might properly assert it.

Compositionality: A theory of meaning is said to be compositional when (a) it has only finitely many axioms and (b) it delivers up meaning-specifying theorems on the basis of those axioms in such a way that the semantic structure of the sentences of the language is thereby exhibited. Intuitively, a compositional theory of meaning would serve up a meaning-specifying theorem for "The man with the red nose is drinking whisky" on the basis of the meanings of its constituent words and their mode of syntactic combination. An example of a non-compositional theory of meaning for a language with only finitely

many sentences would be a long list of meaning-specifying theorems, one for each sentence of the language; an example of a non-compositional theory of meaning for a language with infinitely many sentences would be provided by an infinitary axiom schema such as *A is True iff P*, where "*P*" could be replaced by any declarative sentence of the language concerned and "*A*" by the quotational name of that sentence (assuming, for simplicity, that the correct form of a meaning-specification is a statement of truth-conditions). The construction of compositional theories of meaning is thought by some philosophers to throw light on such phenomena as Semantic creativity and the learnability (q.v.) of natural languages. (See Chapter 12, TACIT KNOWLEDGE.)

Context: The context of an utterance is the situation in which it occurs. The context is often needed to resolve questions about what words stand for. Context can be relevant, however, in different ways. Sometimes it is relevant to determining which expressions are used. Sometimes it is relevant to the resolution of ambiguities: to determine with which meanings expressions have been used. In the case of indexicals, context remains relevant when both the identity and the meaning of expressions are known, for the meanings of the expressions are rules that fix the designation of the expressions relative to contextual factors.

Context Principle: A principle enunciated in several forms by Frege in his *Foundations of Arithmetic* (1884: Eng. trans. 1959), asserting that it is only in the context of a complete sentence or proposition that a word has meaning (*Bedeutung*). In *Foundations*, Frege undoubtedly appeals to the principle to justify his view that it is not necessary for a word to have meaning that we should be able to point to what it stands for, and thence in arguing against psychologistic tendencies which seek to identify the meaning of number-words with mental entities. It is also taken by him, at least during his middle period, as justifying the procedure of defining terms contextually. Both its interpretation and its wider bearing upon issues in the philosophy of language and ontology are controversial. This is in part because, at the time of writing *Foundations*, Frege had not explicitly drawn his celebrated distinction between sense (*Sinn*) and reference (*Bedeutung*), so that it is unclear whether the principle should be taken as applying to sense, or to reference, or to both. Taken as applying to sense, the principle may be seen as underpinning his view that the sense of sub-sentential expressions consists in their contribution to the sense of complete sentences containing them, and so as supporting a position intermediate between semantic atomism at one extreme and Semantic holism (q.v.) at the other. Taken as applying to reference, the principle may be seen as underpinning the view (to which Frege also subscribes) that it suffices for terms to have reference that they figure as parts of more complex expressions (e.g., sentences) which have reference.

Convention: The fundamental idea in the application of the notion of convention to language is to capture the arbitrary nature of the association between a word and its meaning. This *idea* is not in dispute by philosophers, despite the fact that at least one philosopher does deny that language is conventional. To understand this it is necessary to understand that the concept of convention has come to be associated with the idea of a kind of rational control by speakers over the meaning of their words. It is this that some philosophers dispute. Thus one finds two positions in the literature: (1) language is conventional in the sense of being both arbitrary and under speakers' rational control, and (2) language is conventional only in the sense of being arbitrary. At least one philosopher (Davidson) claims to reject the idea of language as governed by conventions altogether (see postscript to Chapter 13, RADICAL INTERPRETATION); however, on closer inspection

one finds that the idea that meaning is arbitrary is still retained (only the association between this idea and convention is abandoned).

Convention T: see **Criterion of material adequacy**

Counterpart theory: An alternative semantics for quantified modal logic, due to David Lewis. In standard semantics, a sentence '*Possibly, Fa*' is true iff there is a possible world in which *a* is *F*. In counterpart-theoretic semantics, '*Possibly, Fa*' is true iff there is a possible world in which some counterpart of *a* is *F*. In Lewis's own version the counterpart relation is determined by similarity, but this philosophical view about the nature of counterparthood is only one of many that are consistent with the semantics.

Criterion of identity: The general notion of a criterion of identity is the notion of a standard by which identity is to be judged. A paradigm is Frege's example: the criterion of identity for directions is parallelism of lines. In this case the criterion of identity for one type of object is a relation between objects of another type. One question about criteria of identity is whether this must always be the case, or whether a criterion of identity for one type of object can be a relation between objects of the same type. A second question is whether a criterion of identity needs to be a relation at all. A standard, though controversial view is that reference to an object is only possible against the background of a criterion of identity, and hence that any proper name must have as part of its sense a criterion of identity.

Criterion of material adequacy: When Tarski set out to define "true sentence of language L," by the systematic determination of its extension, he stipulated that the definition should be formally rigorous, should make no use of semantic notions, and should in addition be *materially adequate*, or, in other words, should grasp the current meaning of the notion of truth as it is known intuitively. The definition must be faithful to the substance of the notion, in other words. What this involved (see Chapter 2, MEANING AND TRUTH-CONDITIONS, §§16–17) was that the definition should *entail*, for each sentence of the language for which "true sentence" is to be defined, a biconditional of the form:

True x if and only if p

where the "x" holds a place for a designation of the sentence in question, and "p" holds a place for a translation of the sentence into the metalanguage in which the definition is being constructed. In the case where the object-language is a proper part of the metalanguage, the object-language sentence will count as a translation of itself. The same sentence, say "snow is white," is then referred to on the left-hand side and used on the right-hand side of the biconditional that the truth-definition must entail.

NB. A biconditional such as '"snow is white" is true if and only if snow is white' would be called in propositional logic a material equivalence. This use of the word "material" in logic has absolutely nothing to do with what Tarski means by material adequacy in his statement of Convention T. The material adequacy of a truth-definition involves the fidelity of the definition to the intuitive notion of truth. Material adequacy is seen by Tarski as a *substantial* requirement.

***De dicto* and *de re* ascriptions:** One can ascribe a property – or a "mode" of having a property, such as having it necessarily – to what a sentence says (a *dictum*) or to an individual (a *res*). Ascriptions of the first sort are *de dicto*, of the latter *de re*. To say that the claim that my mother had no children is possibly true is to make a (silly) *de dicto* ascription; to say, of my mother, that she might have been childless, is to make a (true) *de re* one. *De re*, but not *de dicto*, modal ascriptions have implications about the essential properties of an

object. Sentences with quantifier phrases and operators (such as 'my mother might not have had a child') are often ambiguous between a *de dicto* and a *de re* reading. Some, such as Quine, have challenged the intelligibility of *de re* modal claims and of devices, such as quantification into modal contexts, typically used to make them.

De dicto and *de re* propositional-attitude ascriptions are distinguished as above: the first relates one to a *dictum* (a proposition); the latter to an individual and an attribute. In a *de re* ascription, such as 'Kristen believes, of my mother, that she is childless,' the position which picks out the *res* (here, that of 'my mother') is transparent; in a *de dicto* reading of 'Kristen believes that my mother is childless,' the position of 'my mother' is opaque. It is a matter of dispute whether this distinction, between ways of *talking* about attitudes, corresponds to a distinction between *kinds* of attitudes – whether, for example, there is a special kind of *de re* belief which involves an epistemically significant connection or acquaintance with an object.

***De re* senses:** A *de re* sense is a mode of presentation of an object which cannot be entertained if that object does not exist. *De re* senses were first introduced as such in the works of John McDowell, such as "On the sense and reference of a proper name," *Mind*, 86 (1977), pp. 159–185, and Gareth Evans, as in "Understanding demonstratives," in H. Parret and J. Bouveresse (eds), *Meaning and Understanding* (De Gruyter, 1981) and *The Varieties of Reference* (Clarendon Press, 1982), in which they attributed the notion to Frege.

According to *de-re*-sense theorists there are classes of terms which, when used, express *de re* senses, if they have content at all. If an occurrence of a term in such a class does not denote, then it does not have a sense, and hence is contentless. The most plausible candidates for terms, occurrences of which express *de re* senses, are demonstratives and indexicals. For instance, according to Evans (1982, ch. 6), grasp of the sense of an occurrence of a demonstrative, such as 'this.' is constituted in part by the existence of an "information link" between the denotation of that occurrence of 'this' and the subject. If an occurrence of 'this' does not denote, then there is no such information link, and hence nothing that would count as grasping the sense of that occurrence. But a sense which is such that there is nothing for it to be grasped is not a sense at all. Hence, if an occurrence of "this" does not denote, then according to Evans's account, it lacks a sense, and so is contentless.

Deflationary conception of truth: The view that the predicate 'true' does not stand for any real property, but, excepting its use in indirect endorsements (e.g., 'Fermat's last theorem is true') or compendious ones (e.g., 'Everything he said is true'), is no more than a device of Disquotation (q.v.).

Degree of truth: If two things are borderline cases of red, but one is redder than the other, the redder one is, intuitively, a better candidate for being something of which "red" is true. One might try to capture this idea in terms of "red" being more true of the redder object than of the less red. This gives one an ordering. One might try to use this, along with further data (e.g., comparisons between closeness of pairs in the order) to create a scale. Finally, one might find end-points, to correspond to definite truth and definite falsehood. The points on such a closed scale are degrees of truth. Applied to vagueness, a degrees-of-truth theory does good justice to our feeling that a vague statement is not completely true, but encounters many difficulties, including ones relating to the assignment of degrees to complex sentences, and ones relating to higher-order vagueness.

Denoting versus naming: see **Referentialism**

Describing versus referring: see **Referentialism**

Direct reference: 1. Say that a term (or its use) is *Fregean* if its reference at each possible situation s is what is presented or described, at s, by the term's sense (or by some descriptive condition which the term supplies). A *directly referential* term is one whose uses are *non-Fregean*, since the term's referent, at each situation, is semantically constrained to be the actual referent. David Kaplan, who introduced the terminology, argued that demonstratives and proper names are devices of direct reference. Note that, on this use, a directly referential term may make a "descriptive contribution" to what a sentence says, so long as that contribution is truth-conditionally irrelevant.

2. On another usage, a directly referential term is one whose sole contribution to what a sentence says is its referent; sentences with such terms express singular propositions. Direct-reference accounts of propositional-attitude talk take demonstratives and names to be thus directly referential, and take attitude ascriptions to ascribe (only) relations to the propositions determined by their complements.

Disjunction problem: The disjunction problem is a problem for crude causal accounts of reference and truth-conditions. On a crude causal account the truth-condition of a belief-type B is the type of states of affairs that cause B. The difficulty is that if the state of affairs S causes the belief B, and the state of affairs S* causes the belief B, then the disjunctive state of affairs S or S* causes B. That is, according to the theory, B's truth-conditions are the disjunction of all its causes. This makes error impossible. Naturalistic semantic theories attempt to deal with the problem by specifying a distinction between those causes that constitute B's truth-conditions and those that don't.

Disquotation: According to the disquotational principle for the predicate 'true,' a true biconditional results whatever sentence is substituted for the variable 'P' in the scheme:

'P' is true if and only if P

If it is granted that truth is properly predicated of sentences (as distinct from the thoughts or propositions which sentences may be used to express), and provided that the sentence quoted in the left-hand component of the biconditional is taken to be (a quoted version of) the sentence used in the right-hand component, it appears indisputable that this principle captures a fundamental feature of the notion of truth, since the principle, so understood, appears to be no more than a metalinguistic version of what is usually called the Equivalence Thesis: It is true that P if and only if P. An associated – but much more controversial – thesis is that the predicate 'true' does not stand for a genuine property, and is little more than a device of disquotation, needed only for the purpose of indirect or compendious endorsement (as in 'Pythagoras's Theorem is true' and 'Whatever Aristotle says is true,' respectively) – this is the Deflationary conception of truth (q.v.). Closely related is the famous Redundancy Theory, according to which there is no more to (the concept of) truth than is involved in accepting all instances of the disquotation principle, or the Equivalence Thesis.

Effectively decidable: A statement is effectively decidable if there is a routine procedure which can be followed in any given case and which is guaranteed to lead to a correct decision as to the statement's truth-value. Derivatively, a predicate is said to be (effectively) decidable if there is a routine procedure for determining, with regard to an object (or sequence of objects, in case of an n-place predicate for $n \geq 2$) whether it satisfies that predicate – equivalently, whether the predicate is true of that object (or sequence of objects). Effectively decidable statements are, by their very nature, incapable of being undetectably – or Evidence-transcendently (q.v.) – true.

Epistemic conception of meaning: In one usage, this denotes the view that to understand a word or sentence is to know rules (i.e., conventions) which govern its role in our language practices, in particular of assertion and inference. Rules governing the use of words take the form of conventions for introducing and eliminating terms in a language; they in turn determine when a sentence is assertible and what is inferable from it.

In another distinct, but perhaps related usage, an epistemic conception of meaning is any view which insists that sentence meanings be given in terms of conditions whose satisfaction is always, at least in principle, a recognizable matter – such as conditions of warranted assertion, rather than Evidence-transcendent (q.v.) truth.

Epistemic conception of vagueness: This is the view that vague statements are either true or false (and not both) in borderline cases, although we cannot know which (see **Bivalence**). Similarly, on this view, the major premise of a sorites paradox, for example, 'For all n, if n + 1 grains make a heap then n grains make a heap,' is falsified by some number n, although we cannot know which. The epistemic view permits the retention of classical logic, truth-conditional semantics, and Disquotational principles about truth (q.v.) for vague languages. It is not implied that every unknowable truth is vague. Rather, the view identifies vagueness with a particular kind of unknowability whose origin is conceptual.

Epistemic possibility/necessity: Modal words ('possible,' 'necessary,' 'may,' 'must,' etc.) are sometimes used to express claims about what is possible, or necessary, given our state of knowledge or information. Thus when we say of some acquaintance whose intentions are as yet unclear to us, and are perhaps not yet determinate, that she may come to the party, we are probably not merely claiming that it is a bare logical possibility that she will come, but that we know of nothing from which it can safely be inferred that she will not come. If so, our claim is one of epistemic possibility. A correlative use of 'must' to express epistemic necessity is perhaps exemplified when we say, when the person we are expecting to meet conspicuously fails to alight from the train, that she must have missed it. This use of modal words needs to be carefully distinguished from their use to express other kinds of necessity and possibility, since what is epistemically possible may well not be, for example, logically or metaphysically possible. Thus it is plausible, at least, that whichever of Goldbach's Conjecture (that every even number greater than 2 is the sum of two prime numbers) and its negation is true, is necessarily true. But in our present state of knowledge, both the Conjecture and its negation are epistemically possible.

Error theories: An error theory for a given area of discourse maintains that statements belonging to the discourse are aimed at truth, but are systematically false, owing to the failure of some presupposition – usually ontological in character – of the discourse as a whole. Thus an error theory contrasts with certain other types of anti-realist position, according to which statements of the seemingly problematic kind are to be reinterpreted in some way; for example, by reductive translation into statements of some other unproblematic type, or, quite differently, by construing them as having some other than assertoric function (as on the emotivist theory of ethical utterances, according to which they are aimed not at stating facts but at evincing feelings or attitudes). In the classic example, John Mackie maintained that ordinary moral discourse is error-ridden because there do not exist the distinctively non-natural properties or moral facts required for the truth of its statements. Other examples are the view that mathematical statements are uniformly false because their truth would call for the existence of number, sets, or other kinds of

abstract entity (denied by the error theorist, in this case a nominalist); and eliminativist views about 'folk'-psychological discourse.

Essential property: A property *P* is traditionally said to be an essential property of an object *x* if *x* could not lack *P*, or, better, if *x* could not exist while lacking *P*. Without the qualification about existence, no property would be essential to a contingently existing object if possession of the property by an object required the object to exist. Unfortunately, with the qualification about existence, existence itself becomes an essential property, which is not the intent of the traditional notion.

Essentiality of origin: A thesis due to Kripke and sometimes called 'the necessity of origin.' It claims that the origins of things of certain specified kinds are essential to them. For instance, an individual human being may be said to originate essentially from the zygote he or she in fact originated from. The thesis can also be applied to more abstract entities to which the notion of origin is applicable, such as species.

Euthyphro contrast: The Euthyphro contrast, prominent in a good deal of recent discussion of realism and opposed positions, and especially in the work of Crispin Wright, concerns whether our best judgments in a given area are to be regarded as tracking an independently constituted realm of facts (the realist view) or whether, rather, we should view truth for the discourse's statements as somehow determined by, or constituted out of, our best judgments (the anti-realist option). The label recalls Plato's dialogue, which has Plato maintaining that pious acts are thought to be so by the gods because those acts are pious, while Euthyphro contends for the opposed view, that pious acts are so because the gods take them to be so. Realist and anti-realist may be presumed to agree that there will be a coincidence between the facts of the matter and our judgments made under optimal conditions. The issue then concerns the direction of dependence: are such judgments true because they match up with independently constituted facts, or are those facts themselves no more than a reflection of our best judgments? (See also **Cognitive command**, **Wide cosmological role.**)

Evidence transcendence: To hold that statements of some kind may be evidence-transcendently true or false is to claim that such statements may have determinate truth-values without its being possible, even in principle, for us to discover what those truth-values are. It is standardly taken to be a mark of a certain type of realism with respect to a class of statements to maintain that those statements may be evidence-transcendently true, or false. A realist of this kind holds that the meanings of (at least some of) our sentences are to be given in terms of truth-conditions, the satisfaction of which is a potentially evidence-transcendent matter. The opposed anti-realist contention is that the only notions of truth and falsehood which we may justifiably employ are evidentially or epistemically constrained notions according to which there is an essential connection between truth-values and evidence (and hence between sentence meaning/truth-conditions and evidence). (See also **Bivalence.**)

Expressivism: An expressivist treatment of a given region of discourse maintains that, whatever the surface grammatical form of its characteristic utterances may suggest to the contrary, those utterances are not genuinely assertoric or descriptive, aimed at conveying truths concerning a certain subject-matter, but are instead properly to be understood as serving to express feelings or attitudes. A classic example is the logical-positivists' treatment of ethical utterances – anticipated by David Hume and generally known as the emotive theory – as serving to evince feelings of moral approval or disapproval.

Extension/Intension: *Extension* is a generalization of the notion of reference. Standardly, the extension of a singular term is its referent; of an adjective, noun, or verb, it is the collection of things of which it is true; of a sentence, it is its truth-value. Extensions can be assigned to other meaningful expressions, such as quantifiers.

Some languages are *extensional*. Substitution of expressions with the same extension doesn't change the extension of the whole. (Interpreted) versions of first-order logic are examples: Replacing term *t* with term *s* in a sentence can't change the sentence's extension (truth-value) in such languages, if *t* and *s* have the same extension (referent); likewise, interchange of co-extensive predicates cannot alter a sentence's truth-value. Natural languages certainly don't *seem* extensional (though some have claimed otherwise): 'centaur' and 'unicorn' have the same extension; 'wanted to see a centaur' and 'wanted to see a unicorn' do not.

Intension is used in a variety of ways. A standard use identifies an expression's intension with some aspect of meaning which determines extension. A technical but important use is from possible-worlds semantics, where expressions receive extensions relative to "possible worlds"; an expression's intension is the rule or function assigning its extension at each world. Modal languages are typically intensional – the intension of an expression being determined by the intensions of its parts – but not extensional. David Lewis, Richard Montague, and Robert Stalnaker have identified propositions and properties with possible-worlds intensions.

External realism: see **Metaphysical realism**

Externalism: Externalism is the view that semantic properties of at least some concepts and thoughts, especially the properties of making reference to certain entities and of having certain truth-conditions, do not supervene on intrinsic properties of mental or neural states. Arguments for externalism are mostly appeals to intuitions concerning thought-experiments in which thinkers are supposed to be identical with respect to their intrinsic properties, but are in different environmental contexts: see Hilary Putnam, *Mind, Language and Reality: Philosophical Papers*, vol. 2 (Cambridge University Press, 1975), pp. 223–229. If externalism is true then the facts in virtue of which the semantic properties of concepts and thoughts are instantiated must involve relations between the thinker and her environment.

Facts: Our conception of a fact is ambivalent, in a philosophically confusing way. On the one hand, facts belong to the world and are not of our making (except in so far as we have made the world as it is: the fact that there is coffee here is due to something I did). In the traditional version of the correspondence theory of truth, facts in the world are what true propositions correspond with. On the other hand, many people think the fact that Caesar crossed the Rubicon is a different fact from the fact that the conqueror of Gaul crossed the Rubicon, even though there must be a sense in which only one thing happened. There is a case for saying that ordinary language encourages us to individuate facts as finely as we individuate statements or propositions; hence Strawson's ("Truth," *Proceedings of the Aristotelian Society*, suppl. vol. XXIV (1950) pp. 129–156) thought that facts are just what true statements state. This can mislead people into thinking that, since facts are individuated by the concepts we use to express them, the reality to which true statements correspond cannot be fully independent of how we think about it and the concepts we employ. It might be better to give up calling that reality "the facts."

First-order languages: By a first-order language is meant, primarily, a formal language whose logical vocabulary comprises sentential connectives (usually negation, conjunction,

disjunction, the conditional, and the biconditional), together with quantifiers binding just individual- or name-variables. It is the latter condition which determines the order of the language. Higher-order languages contain, additionally, quantifiers binding variables ranging over entities of other kinds, such as properties and relations. Thus '$\forall xFx$' and '$\exists x \exists y Gxy$' might be sentences of a first-order language, since they involve only quantification over individuals; but '$\forall F \forall x(Fx \vee \neg Fx)$' must belong to a language of (at least) the second order, since it involves quantification over properties of individuals. A language will be second-order if it permits quantification over properties and relations of individuals, but not quantification over entities of any 'higher' type, such as properties of properties of individuals, and so on. By a natural extension, 'first- (or second-, etc.) language' may be used to refer to natural languages whose logical vocabulary does not exceed that of first- (or second-, etc.) formal languages.

Frege's Puzzle: Frege's Puzzle is this: How can (uses of) sentences which differ only by terms referring to the same thing differ epistemically (for example, in how informative they are)? This is a puzzle for anyone who believes (a) what a sentence use says is individuated in terms of what the user speaks of in using the sentence (so that what 'Loetze wrote' says turns on the reference, not the sense, of 'Loetze'); and (b) that the epistemic properties of a sentence supervene on what it says. Frege's puzzle is the occasion for Frege's introduction of the notion of sense; it is seen as a major embarrassment for contemporary "direct reference" (q.v.) accounts of assertion.

Full-blooded vs. modest theory of meaning: Contrast introduced by Michael Dummett. A modest theory of meaning for a language is, as he puts it in *The Seas of Language* (Oxford University Press, 1993), p. viii, not intended to "convey the concepts expressible" in it, but to "convey an understanding of that language to one who already had those concepts." A full-blooded theory should also specify what it is for a speaker of the language "to possess the concept it expresses."

Generality Constraint: The Generality Constraint is a version of the principle of compositionality. Applied to linguistic understanding, it entails that the ability to understand, say, a simple subject-predicate sentence Fa is composed of distinct abilities, the ability to understand a and the ability to understand F. These abilities must, furthermore, be manifested in the understanding of other sentences involving a and F.

A more exact characterization of the Generality Constraint (as applied to linguistic understanding) is as follows. Let e be an expression. If someone understands e, then that person possesses the ability to understand every sentence S which results from placing e into the open position of some linguistic string L which satisfies the following conditions (1) that person understands all the expressions in L (and the person has a mastery of the relevant ways of composing the elements of the resulting sentence); (2) the result is syntactically and semantically well-formed; and (3) the result is not too complex to be processed by the speaker.

For example, suppose it is claimed that someone understands the predicate, 'feels pain.' If the Generality Constraint is true, then that person must also have the ability to understand sentences such as "I feel pain" and "Bill feels pain," if she grasps the first-person pronoun, the name "Bill," and predication. (Thus, the possibility that someone has an understanding of their own mental self-ascriptions, and third-personal physical ascriptions, but no understanding of third-personal mental ascriptions, is inconsistent with the Generality Constraint.)

Traditionally, the Generality Constraint is formulated as a prerequisite for possessing the ability to entertain thoughts, rather than in terms of linguistic understanding.

The Generality Constraint was first introduced and put to use in chapter 3 of Strawson's *Individuals* (Methuen, 1959), though it is implicit in many defenses of the compositionality of language and thought.

Higher-order vagueness: The word 'heap' has first-order vagueness because it can have borderline cases; it has second-order vagueness because the expression 'borderline case of "heap"' can itself have borderline cases. More formally, suppose that there is a standard way of constructing a metalanguage for any given language, in which any vagueness in the latter can appropriately be described. Given a language L, inductively define a sequence of languages L_1, L_2, L_3, … by letting L_1 be L itself and L_{n+1} be the metalanguage for L_n. Then L is nth-order vague if and only if L_n is vague in the ordinary sense; L is higher-order vague if and only if it is nth-order vague for some $n \geq 2$. Corresponding notions of vagueness can be defined for individual expressions. It is plausible that all natural languages are nth-order vague for all n. Theories of vagueness often have difficulty in accommodating higher-order vagueness because they treat the metalanguage for a vague language as though it were precise.

Homophonic specification of meaning or of reference, or of truth-conditions: When the object-language (containing the expressions whose meaning/reference/truth-conditions are to be given) forms part of the metalanguage (in which the specification is to be effected), those meanings, and so on, may be specified homophonically, by using those very expressions themselves. Thus:

'cat' means cat
'mice' refers to mice
'cats eat mice' is true if and only if cats eat mice.

Hyperintensional: 1. Properties and propositions (thought of as what predicates and sentences express) are sometimes identified with constructions out of things such as possible worlds. *Hyperintensional* theories hold that propositions (and/or properties) are basic entities, not reducible to constructions from worlds or the like, and that they are more fine-grained than constructions from possible worlds (since, for instance, predicates can express different properties although they have the same intension).

2. Linguistic contexts in which expressions with the same (possible-worlds) intension are not inter-substitutable *salva veritate* are sometimes called *hyperintensional*. Propositional-attitude contexts are the paradigm of such linguistic contexts.

Implicature: Speakers often communicate something other than what they strictly and literally say. For example, a speaker might use the words, "There is a restaurant nearby" in order to say that there is a restaurant nearby and might thereby communicate, in addition, that they expect the restaurant to be open. Grice drew attention to the importance of this distinction between what is strictly and literally said (more generally, basic speech acts) and other things communicated by saying it (more generally, non-basic, or derivative, speech acts), and used the label *implicatures* for what is communicated without being strictly and literally said. In addition to drawing attention to these distinctions, Grice aimed to account for the ways that implicatures can be generated and discerned. As part of that project, he also distinguished between what he called *conversational implicatures* – implicatures that can be discerned on the fly by exploiting general principles governing rational communication – and *conventional implicatures* – which may have originated as conversational implicatures, but now need to be learned by rote.

Indeterminacy of translation: The thesis, associated with Quine, that the methods of Radical translation (q.v.) do not uniquely determine a single translation from one language to another. In other words, no matter how much linguistic–behavioral data radical translators of a given language have to go on – indeed, even if they had access to all such data available in principle – they could still arrive at distinct manuals of translation which, while making optimum sense of the native speakers' linguistic behavior, were in conflict with each other about the correct translation of particular expressions. The thesis of the indeterminacy of translation proper maintains that this conflict can take the form of a divergence over the *truth-conditions* of certain sentences, so that one optimal manual of translation may represent a particular utterance as saying something true, while another represents it as saying something false. In a weaker form, however, the thesis is that the assignment of reference to the constituents of a sentence – singular terms and predicates, for instance, occurring within it – can vary, even though the truth-conditions of the sentence be fixed (see **Inscrutability of reference**).

Indexicals: Indexicals are words such as "I," "you," "here," and "now." The designation of such words (what they "stand for") shifts from use to use, depending on various contextual factors. The designation of "I" depends on who the speaker is; the designation of "you" on the intended audience; the designation of "now" on the time, and so forth. Demonstratives such as "this" and "that," and demonstrative phrases such as "that man" or "this computer," are usually reckoned to be a subclass of indexicals.

Indiscriminability: To discriminate between *x* and *y* is to recognize a difference between *x* and y. Thus *x* and y are indiscriminable if and only if no difference is recognizable between them. Things may be indiscriminable in one respect and not in another (e.g., in color but not in shape), by one means and not by another (e.g., by chemical analysis but not by touch), by one person and not by another, when presented in one way and not when presented in another, and so on. In general, indiscriminability is a reflexive and symmetric, but not transitive relation: each term in a series may be indiscriminable from its neighbors, even though the first and last terms are easily discriminable. Sorites paradoxes (see Chapter 28, SORITES) result from the assumption that whenever two things are indiscriminable, an observational term correctly applicable to one must also be correctly applicable to the other.

Individual essence: Intuitively, the individual essence of a thing is those features of it which in some sense make it what it is, or constitute its identity. A collection of essential properties is an individual essence of an object *x* if it is not possible for any object other than *x* to possess them all. However, this definition is consistent with a thing's having more than one individual essence, and so does not entirely capture the traditional notion.

Informational theories of truth-conditional content: According to informational theories, the truth-condition of a belief-state B is the information that B carries, or would carry under certain circumstances: see F. Dretske, *Knowledge and the Flow of Information* (MIT Press, 1981). Different accounts result from different specifications of the circumstances in which information determines truth-conditions. For example, optimal-conditions theories specify the conditions as ones which are epistemically optimal: see R. Stalnaker, *Inquiry* (MIT Press, 1984), J. Fodor, "Psychosemantics, or where do truth conditions come from?" in W. Lycan (ed.), *Mind and Cognition*, (Blackwell, 1990). These are conditions in which B is tokened if and only if it is true. Certain teleological theories specify the truth-condition-constituting information as the information that it is B's biological function to carry: see R. Millikan, "Biosemantics," *Journal of Philosophy*, 86 (1989) and D. Papineau, *Philosophical Naturalism* (Blackwell, 1993). The accounts so far

devised seem either to appeal to intentional specifications of truth-condition-constituting circumstances or to fail to assign determinate truth-conditions.

Inscrutability of reference (see also **Indeterminacy of translation**)**:** The thesis that the truth-condition of a sentence, and hence its truth-value across all possible worlds, may be held constant consistently with variations in the assignment of reference to its constituents, in particular to the singular terms and common nouns which it may contain. That the thesis holds is the gist of Quine's famous 'gavagai' argument, and is ostensibly established in a very general form by Putnam's permutation argument (see **Permutation argument**).

Intension: see **Extension/Intension**

Intensionality: A context is intensional just if its truth-value is liable to be altered by the substitution within it of expressions which have the same Extension (q.v.) as those for which they are substituted. The principal examples of such contexts are modal sentences, sentences ascribing intentional attitudes (see **Intentionality**), and contexts of direct quotation. Thus, it is necessary that nine is greater than seven, but not necessary that the number of planets is greater than seven, although "nine" and "the number of planets" have the same extension (i.e., reference). Again, someone may believe that all lions have hearts without believing that all lions have kidneys, although "has a heart" and "has kidneys" have the same extension (i.e., are true of the same things). Likewise, 'Richard was called "Cœur de Lion" because of his bravery' may be true, while 'Richard was called "Richard I" because of his bravery' is doubtless false, although "Cœur de Lion" and "Richard I" have the same reference.

Intention-based semantics: Intention-based semantics is a term that has been used by Stephen Schiffer to refer to Grice's analysis of meaning. The title captures the centrality given to the concept of intention in this analysis. This title also brings out the way in which Schiffer once used Grice's work as part of a larger program of reducing semantics to psychology and psychology to the physical-cum-functional.

Intentionality: That characteristic of mental states which consists in their being *about* something, in their being directed upon some particular (putative) object or state of affairs. The term was coined in this technical sense by the Scholastics (from the Latin *intendo*, "to point") and revived by Brentano, who held that intentionality defines the distinction between the mental and the physical, and constitutes a decisive barrier to any kind of reduction of the former to the latter. Brentano held, more specifically, that the intentionality of the mental shows itself in two characteristics: mental states may be indifferent to the non-existence of their objects – the mere fact that the Holy Grail does not exist is no barrier to Gawain's being correctly described as hoping to find it – and they are typically sensitive to variation in the mode of presentation of the object they concern – Lois Lane may hope to marry Superman, but not hope to marry Clark Kent, for instance, even though they are one and the same.

Derivatively, certain kinds of psychological sentences are described as intentional when they exhibit corresponding linguistic features, that is, do not sustain widescope existential generalization and are prone to the kind of substitution failures associated with Intensionality (q.v.). Ascriptions of propositional attitude – belief, desire, hope, fear, intention, and so on – are paradigms of such intentional contexts.

Interpretation: In general terms, an interpretation of a language is an assignment of meanings to the expressions of the language. In the context of the semantic study of formal languages employed in logic, the term 'interpretation' bears a somewhat more precise

meaning, which may be illustrated here for the case of a First-order language (q.v.) with logical vocabulary comprising the usual sentential connectives and quantifiers binding individual variables. Giving an interpretation, then, consists in specifying a (non-empty) set – the domain of the interpretation – and, on this basis, assigning references to the various items of primitive non-logical vocabulary, which will always include a selection of predicates, and may also include functional expressions and individual constants. The general idea is that these assignments should be made in such a way as to induce, via the fixed meanings of the logical expressions, truth-values on the sentences of the language, which are then said to be true, or false, relative to that interpretation. The individual variables range over the specified domain, that is, they may take any of its elements as values. Each 1-place predicate is assigned a subset of the domain – intuitively, the objects in the domain of which it is stipulated to be true on that interpretation; 2-place predicates are assigned sets of ordered pairs of elements of the domain; 3-place predicates sets of ordered triples, and so on. Individual constants are assigned elements of the domain, and functional expressions are assigned functions taking objects in the domain as arguments and yielding objects in the domain as values. Thus a simple sentence 'Rab' will be true under an interpretation I if and only if the ordered pair of elements of I's domain assigned to the constants 'a' and 'b' respectively belongs to the set (of ordered pairs) assigned to the 2-place predicate 'R.' The universally quantified sentence '∀xFx' will be true under I if and only if 'Fx' is true no matter which element of I's domain is taken to be the value of the variable 'x' (i.e., iff every element of the domain belongs to the set assigned to 'F'). A conjunction of sentences 'A & B' will be true under I iff both 'A' and 'B' are separately true under I. And so on.

In terms of these basic ideas, certain further important semantic concepts may be defined. For example, an interpretation I is said to be a model of a set of sentences Γ iff every sentence in Γ is true under I. An inference Γ ⊢ A is valid iff every model of Γ is also a model of {A}. A sentence A is logically true iff every interpretation of A's language is a model of {A}.

Kinds: Kinds are Universals (q.v.), having Particulars (q.v.) as their instances. Terms denoting kinds belong to the more general categories of Sortal terms (q.v.) and Mass terms (q.v.). Examples belonging to the former category are 'tiger' and 'lemon,' while examples belonging to the latter are 'gold' and 'water.' All of these are examples of *natural kind* terms, which are to be contrasted with terms for *artifactual* kinds, such as 'pencil' and 'yacht.' A distinguishing feature of natural, as opposed to artifactual, kinds is that they are typically subjects of natural scientific law (for example, it is a natural law that gold consists of atoms containing 79 protons in their nuclei). It is nowadays widely held that natural kind terms are Rigid designators and consequently not definable by means of complex descriptions in the way that empiricist philosophers such as John Locke believed them to be.

Law of Excluded Middle: The law claims that every instance of 'P or not-P' is true, or is a theorem. This is guaranteed by Bivalence (q.v.), given that 'not' toggles truth-values. However, it can hold without bivalence, for example in a three-valued system in which 'not' turns any non-truth into a truth. Among theories of vagueness, supervaluation theories maintain the Law of Excluded Middle, while departing from bivalence: some sentences are neither true (that is, true-on-all-valuations) nor false (that is, false-on-all-valuations); but every instance of 'P or not-P' is true-on-all-valuations and so true.

Leibniz's Law: Leibniz's Law is the principle that if *a* is identical with *b* every property of *a* is a property of *b*. It is what distinguishes *absolute* from any form of *relative* identity.

There are many apparent counter-examples involving psychological and modal properties, but these cannot be genuine counter-examples, since Leibniz's Law is definitive of absolute identity. Thus Leibniz's Law must be sharply distinguished from the false principle of substitutivity that if '*a*' and '*b*' are two singular terms for the same object, then replacement of '*a*' by '*b*' will be possible *salva veritate* in any context. Leibniz's Law is not in formal conflict with the Relative Identity Thesis (q.v.) of Peter Geach, since the latter entails not that Leibniz's Law is false, but that it is inexpressible, since no language can contain an expression for absolute identity (q.v.).

LF: LF is a hypothesized level of syntactic structure that encodes features traditionally captured by logical systems, such as variable binding and scope relations between operators. Thus, initially, LF was an acronym of logical form. LF, however, is a syntactic structure and so hypotheses about LF are grounded in otherwise accepted syntactic relations and operations. For example, the scopal properties of quantifiers and other operators are encoded at LF in terms of the movement or displacement of the relevant phrases to higher positions such that the moved phrase scopes over the minimal structure that includes it, with the launch site of movement treated as a bound variable. Crucially, such movement operations are otherwise witnessed throughout language, so the hope is that the particular properties at issue, such as scope, fall under already understood properties of syntax. More generally, LF is hypothesized to be the interface between syntactic structure and semantic interpretation. It remains open, however, just what properties of semantic interpretation are fixed by LF. Thus, LF is not the same notion as logical form (q.v.). LF as classically conceived is a controversial hypothesis, both empirically (not all scope-taking can be understood as movement) and theoretically, due to developments in so-called level-free approaches to syntax.

Locutionary/Illocutionary/Perlocutionary acts: This threefold distinction was adopted by Austin after he abandoned his constative–performative distinction (see **Performative utterances**). A locutionary act is the act of saying something, characterized by Austin as a matter of uttering certain words "with a certain 'meaning' in the favourite philosophical sense of that word, i.e. with a certain sense and with a certain reference": see Austin, *How to Do Things with Words* (Clarendon Press, 1962), p. 94. An illocutionary act is the performance of an act *in* saying something in this sense, such as giving a warning, making a promise, and so on. A perlocutionary act is an act – such as drawing someone's attention to a bull or reassuring them – performed *through* or *by* the illocutionary act.

Logical form: The logical form of a sentence is a formula framed in a logical system (e.g., first-order logic) associated with the sentence. The purpose of the association is to explain the truth-conditions of the sentence (in abstraction from word meaning) and what relations of entailment the sentence stands in. The precise nature of the association is controversial, but a shared conception is that the form may and typically does depart from the apparent grammatical organization of the sentences at issue. Thus, for example, Russell's theory of definite descriptions renders the logical form of sentences of the kind *The F is G* as consisting of three conjuncts, and free variables bound by existential and universal quantifiers. The proposal explains, among other things, why sentences of the target kind may be ambiguous under negation in the way sentences of the kind *N is G* are not (where *N* is a proper name). Similarly, Davidson's (initial) account of 'action sentences' involving transitive verbs renders their logical form in terms of a ternary relation involving a bound variable ranging over events. The analysis explains, among other things, the semantic properties of sentences such as *Bill hit Garry and he didn't like it*,

where the pronoun *it* picks up on the event of the hitting. The general idea of a logical form is widely accepted, even though many disputes remain as to whether the association between logical form and the target sentences is cognitively grounded, a descriptive or theoretical generalization, or a mere paraphrase.

Löwenheim–Skolem Theorems: These are some theorems in the model theory of first-order logic, established originally in several versions by Leopold Löwenheim and Thoralf Skolem, which disclose limitations on the expressive capacity of first-order languages. The Downward Löwenhiem–Skolem Theorem asserts that if a set of first-order sentences has a model at all, that is, an Interpretation (q.v.) in which all the sentences in the set come out true, then it has a countably infinite model (i.e., a model whose domain has exactly as many elements as there are natural numbers). The Upward Theorem asserts that if such a set of sentences has a model in any infinite cardinality, it has models in every infinite cardinality. The theorems have played a central role in one of Hilary Putnam's arguments directed against the position he calls external or Metaphysical realism (q.v.).

***Malin génie*:** The point of the *Malin génie* in Descartes's first *Meditation* is to introduce the most extreme skepticism possible. Some recent philosophers replace the *génie* with a scientist who keeps my brain in a vat, controlling it and all its inputs. The point is the same. No argument could show that I am not being deceived by a *génie*, because the *génie* could make me think arguments sound when they are not; so could the scientist. One can try to undermine the skeptical hypothesis, but one will get nowhere by arguing (as some have) that at least the *génie*/scientist must know some truths; for the *génie*/scientist is only a dramatization of the possibility that our belief-system wholly fails to match the world. The coherence theory of truth attempts to get round it by suggesting that our belief-system, or an idealization of it, determines how the world is. If that were so, there could be no general failure of match. Of course the doubt could still be raised that any particular beliefs (e.g., my present ones) might be mistaken – even my belief that they cohere may yet be false. Perhaps that doubt should not worry us.

Manifestation argument: Common term for an objection (associated particularly with Michael Dummett) to any semantic theory which allows the nature of speakers' private states (see **Privacy**) to influence the meaning of the words they use: it cannot explain how a language-learner could ever show their competence in the language to be learnt. For competence would involve associating the right kind of private state with the words of the language, and whether they are doing this or not can never (by the definition of a private state) be known to anyone else. The manifestation argument is a close relation of the arguments from Acquisition (q.v.) and Communicability (q.v.). (See Chapter 11, MEANING AND PRIVACY.) Interest in these arguments has been aroused by Dummett's suggestion that they support an 'anti-realist' approach to semantics, shifting emphasis away from the conditions under which a sentence is true, perhaps Evidence-transcendently (q.v.) towards those under which a speaker might properly assert it.

Mass terms: Mass terms, such as 'water' and 'gold,' differ from Sortal terms (q.v.) in being dissective: gold is divisible into parts which are themselves gold, unlike the parts of a horse, which are not themselves horses. They also differ from sortal terms in not supplying principles of enumeration for their instances. Thus, whereas it makes sense to ask *how many* horses there are in a field, it only makes sense to ask *how much* water or gold there is in a room. Even so, mass terms do clearly have Criteria of identity (q.v.) governing their use, for it makes sense to ask whether the gold now in this room is the *same* gold as was in this room yesterday.

Meaning-truth platitude: This is the (allegedly platitudinous, and certainly widely endorsed) principle that 'the truth-value of a statement depends only upon its meaning and the state of the world in relevant respects,' a formulation which, along with the term, comes from Crispin Wright's "Kripke's account of the argument against private language," *Journal of Philosophy*, 81:12 (1984), pp. 759–778. The principle plays a central role in his argument that Semantic irrealism (q.v.) leads to an untenable global irrealism. (For discussion, see Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING, §3.)

Mentalese: Mentalese is the name of the hypothesized language in which we think. According to advocates of the existence of Mentalese, for example, J. Fodor, *The Language of Thought* (Harvester, 1976), to think a thought, form a belief, or remember a fact, is to produce, in one way or another (which way depending on whether it is a belief, a memory, etc.), a sentence in an internal language. The existence of Mentalese explains the semantic properties of mental states in terms of the semantic properties of their component Mentalese expressions. This language, unlike natural languages, does not possess its semantics in virtue of the intentions or conventions of its users. Semantic naturalists think that the expressions of Mentalese possess their semantic properties in virtue of natural relations, especially causal and nomological relations, to extra-mental items. The Mentalese hypothesis is usually defended as being part of the best explanation for certain features of thought. The two most prominent features are productivity (a thinker can think complex thoughts) and logical inference: J. Fodor, *Psychosemantics: The Problem of Meaning in the Philosophy of Mind* (MIT Press, 1987).

Metaphysical realism: This term, along with 'external realism,' is employed by Hilary Putnam to refer to an amalgam of several closely associated philosophical ideas about the relations between language and reality, and between truth and knowledge or justifiable belief. One component on which Putnam places considerable emphasis is that even an ideal theory (a theory that is '*epistemically* ideal *for humans*,' ideal by the lights of the operational criteria by which we assess the merit of theories) may nevertheless be, in reality, false. More commonly, Putnam characterizes metaphysical realism in terms of three other theses, of which he takes this feature to be a consequence: that 'the world consists of a fixed totality of mind-independent objects,' that 'there is exactly one true description of the way the world is,' and that 'truth involves some sort of correspondence between words or thought-signs and external things and sets of things.' Putnam attacks this kind of realism, advocating instead what he terms 'internal realism.'

Millian semantics (Direct-reference theory): A Millian, or direct-reference, semantic theory is a hypothesis according to which the semantic value of a proper name (the contribution that it makes to the determination of the content of utterances containing it) is simply the referent of the name. According to this hypothesis, the thought or proposition expressed by a sentence containing a proper name is determined as a function of the individual named, perhaps by containing that individual as a constituent. The contrasting hypothesis is that reference or denotation is mediated by a sense or connotation. According to the contrasting theory, the semantics for the name provides some kind of abstract object – a sense or mode of presentation – which is a constituent or determinant of the thought or proposition expressed, and which also determines a referent.

Minimal truth: The term 'minimalism' is sometimes used to refer to a doctrine about truth not readily distinguishable, if indeed distinct at all, from the Deflationary view (q.v.). However, the term has also been employed (especially in recent work by Crispin Wright, and discussions that this has generated) for a characterization of truth intended to be

neutral as between realists and their various opponents. According to this account, it suffices for a predicate T to be or function as a truth-predicate that it satisfy the Disquotation Scheme: '"P" is T if and only if P' and that it exhibit certain features embodied in or derivable from certain 'platitudes,' as Wright describes them: centrally, that to assert a statement is to present it as true, and that any truth-apt content has a significant negation which is likewise truth-apt.

Modal realism: There are two quite distinct doctrines about modality to which the label 'modal realism' may be applied. Modal realism, in one reasonable sense of the term, is the view that there are irreducible modal truths or modal facts expressible by sentences featuring modal operators or equivalent devices, such as 'Necessarily 17 is prime,' 'Uncles cannot but be brothers,' and so on. Realism in this sense is opposed by any view which denies the existence of a distinctive class of modal facts, either by rejecting modal talk altogether, or by giving a reductive account of it, or by accepting such talk as irreducible but arguing that, properly understood, it has some quite different, non-fact-stating role, as on a Non-cognitivist view (q.v.). In a quite different sense, 'modal realism' denotes a view about the existence of possible worlds. In its extreme form, as famously advocated by David Lewis, this second kind of modal realist holds that there literally are many other possible worlds besides the world we inhabit, each such world being spatially and temporally (and therefore causally) isolated from all other possible worlds. More moderate forms of realism about possible worlds have also been defended, most notably by Robert Stalnaker. It is clear that modal realism in the first sense does not require modal realism in the second. Indeed, since possible-worlds realists favor a reductive analysis of modal idioms to quantification over a domain of possible worlds, the two forms of realism appear incompatible. (For discussion, see Chapter 31, MODALITY.)

Model-theoretic arguments: Model theory is the branch of mathematical logic which studies the interpretation of formal languages (see **Interpretation**). Thus a model-theoretic argument might be any argument that draws on the results or techniques of model theory. In the philosophy of language, model-theoretic arguments which appeal to the Löwenheim–Skolem Theorems (q.v.) and to Permutation results (q.v.) have been deployed by Hilary Putnam, W. V. O. Quine, Donald Davidson, and others in support of conclusions about indeterminacy of reference or meaning. (See Chapter 27, PUTNAM'S MODEL-THEORETIC ARGUMENT AGAINST METAPHYSICAL REALISM, for discussion of Putnam's use of these arguments.)

Myth of the museum: A term used by Quine to stigmatize the idea that there can be facts about the meanings a speaker assigns to particular expressions transcending anything that might in principle be determined as a correct translation of that speaker's utterances by a radical translator. (See **Radical translation**.)

Natural and non-natural meaning: The distinction, drawn in these terms at least, derives from Grice, 'Meaning,' *Philosophical Review*, 66 (1957). Natural meaning (meaning_{n}) is the sort of meaning possessed by things in nature such as clouds (mean rain), or smoke (means fire), or wounds (mean damage). Non-natural meaning (meaning_{nn}) is possessed by our words and sentences, and by some of our actions and gestures. Grice draws attention to a number of differences between the two kinds of meaning; these include the fact that while "x means_{n} that p" entails that p, the entailment fails for meaning_{nn}.

Natural kind externalism: A version of Semantic externalism, according to which the contents of natural kind terms such as 'water,' 'gold,' and 'tiger' are partly determined by features of the external world. Such features typically involve underlying properties

shared by members of the relevant natural kind, such as molecular structure or atomic number. The most famous argument for natural kind externalism is Hilary Putnam's *Twin Earth* thought experiment. (See **Semantic externalism**.)

Necessity of identity: A thesis defended by Marcus, Wiggins, Kripke, and other philosophers, according to which, if objects *x* and *y* are the same, they are necessarily the same. Instances may be formed in ordinary language by replacing the variables '*x*' and '*y*' with proper names or demonstratives, as in 'if Superman is Clark Kent then, necessarily, Superman is Clark Kent.' Since Superman *is* Clark Kent (treating the fiction as fact) it follows that it is necessary that Superman is Clark Kent, a surprising result if one expects everything that is necessary to be discoverable *a priori*. Marcus, Wiggins, Kripke, and others conclude that some necessities are *a posteriori*.

Necessity of origin: see **Essentiality of origin**

Non-cognitivism: 'Non-cognitivism' is probably best understood as a generic term for any of a variety of views concerning some specified region of discourse according to which, to the extent that the surface syntax of its characteristic utterances suggest that they are aimed at recording discoveries (or cognitive achievements), this appearance is misleading. So understood, the non-cognitivist's thesis is a purely negative one – to the effect that the characteristic utterances of the discourse in question do not serve to depict or represent possible objects of knowledge – and is therefore compatible with a variety of positive theses about the function of those utterances. In particular, while it is consistent with, it does not require, the adoption of an expressivist or projectivist theory of the discourse (see **Expressivism** and **Projectivism**).

Normativity of meaning: It is a central ingredient in understanding an expression to grasp that there are associated with it conditions for its correct application. Put another way, it is essential to any expression's possessing whatever meaning it does, that there are rules for its correct use. In this sense, meaning is normative. The normativity of meaning is frequently emphasized in the later writing of Wittgenstein, and especially in his discussions of rule-following: see *Philosophical Investigations* (1953), §§143–242; *Remarks on the Foundations of Mathematics* (2nd edn, 1956, part VI). It is a common theme in subsequent discussion, and especially in Saul Kripke's interpretation of Wittgenstein on rules, where certain attempts to explicate the notion of meaning in naturalistic terms (such as dispositional theories) are criticized as being incapable of accounting for the normative aspect of meaning. (See Chapter 25, THE NORMATIVITY OF MEANING).

Ontological conception of vagueness: This is the view that not all vagueness arises in thought and talk; at least some of it arises in what is thought and talked about, independently of its being thought or talked about. On this view, it may be vague what the spatio-temporal boundaries of an object are, whether one object is part of another, whether objects are identical, or whether a given object has a given property. Such borderline cases are held to result in the failure of the corresponding statements to be either true or false. Some technical treatments of vagueness consistent with the Semantic conception of vagueness (q.v.) are also consistent with the ontological conception.

Ontology: Ontology is the branch of metaphysics which is concerned with the study of being in general. As such, it concerns such matters as the nature of existence and the categorial structure of reality. That all entities occupy distinctive places within a categorial hierarchy is an idea traceable at least as far back as Aristotle. Different systems of ontology propose different categorial schemes. For instance, some schemes regard the distinction between concrete and Abstract objects (q.v.) as being most fundamental,

while others accord this status to the distinction between Universals (q.v.) and Particulars (q.v.). Again, some schemes take the category of substance to be more basic than the category of events, whilst others take the converse view. Yet other schemes take 'particularized qualities' or 'tropes' to be the most fundamental category of physical entities. Ontological categories need to be clearly distinguished from natural kinds (see **Kinds**).

Opacity: An opaque construction turns a position open to the substitutivity of identity into one not open thereto. Take the *doubts that* construction. It maps the word 'Alice' and the sentence

(1) Tully was an orator

to the sentence

(2) Alice doubts that Tully was an orator.

The construction seems opaque. For the position of 'Tully' in (1) is open to substitutivity, since from for example

(3) a = Tully

and (1) the sentence 'a was an orator' follows. But 'Tully' in (2) is not so open, since 'Alice doubts that a is an orator' does not follow from (2) and (3). Constructions not opaque are called *transparent*. (Definition and terminology are due to Quine.)

Not all non-extensional contexts are opaque. For example, given that descriptions are quantifiers, and that proper names and demonstratives are rigid designators (and so, if co-referential, can be substituted in modal contexts *salva veritate*), modal constructions such as *it is necessary that S* are not opaque. But they are non-extensional.

As opacity is a property of constructions, its presence depends upon the presence of grammatical complexity. Quotation, for example, does *not* involve opacity if quotation names are spelling names. For then "Bob" is short for

'B' plus 'o' plus 'b'

which does not contain the word "Bob."

Openness and mutual knowledge: Mutual knowledge is knowledge possessed by two or more individuals. It is a form of iterated knowledge where it is held that A knows that p & A knows that B knows that p & A knows that B knows that A knows that p & …. The iteration here is potentially infinite. Despite the iteration involved in the account of mutual knowledge, some philosophers have held that the regress involved is perfectly harmless, and that it is obviously present in many cases of knowledge. Furthermore, it is taken by some to be a condition of knowledge. Some Griceans have employed a condition of mutual knowledge as a way of ensuring the sufficiency of their analysis of meaning. Without some such condition, the analysis is open to counter-examples based on deception. The concept of openness is designed to do the same work as that of mutual knowledge. Without appeal to an infinite regress of knowledge, the openness condition is meant to ensure that the speaker intend that all her intentions are recognized. In this way the deception which threatens the sufficiency of the analysis is blocked.

Parataxis: On Davidson's paratactic account of

(1) Gettier said that Sleigh slept

grammatical form masks semantical form. To utter (1) is to utter the complete sentence 'Gettier said that,' whose 'that' is a demonstrative; its reference is the ensuing utterance of 'Sleigh slept.' The point of the latter utterance is not to assert that Sleigh slept, but merely to provide a referent for 'that'; the force of the whole thing is something like

(2) An utterance of Gettier said-the-same-as *this* Sleigh slept.

Among the virtues of this view are that it absolves sentences such as (1) from the charge that they violate the principle of substitutivity; and it apparently allows an account of such sentences to get by with only extensional semantic values. Among its apparent vices are that, in many cases (e.g., 'each author said that he would autograph his book'), it is implausible that we relate individuals to utterances; it seems, instead, that we relate them to *interpretations* of (possible) utterances.

Particulars: Particulars are normally contrasted with Universals (q.v.), the former being instances of the latter: for example, a particular apple is an instance of the universal *apple*, which in this case is a natural kind (see **Kinds**). Particulars may be concrete objects, as in this case, or they may be Abstract objects (q.v.), such as numbers and sets. However, there may also be particulars which do not seem to qualify as 'objects' or 'Things' (q.v.) at all, in any very robust sense, such as the particular smile on someone's face, or the particular color of this apple. Items like these are sometimes called 'particularized properties' or 'tropes.'

Performative utterances: J. L. Austin's term, designed to capture the fact that we do things with words. Austin distinguished performative utterances from what he labeled *constatives*. Austin once believed that only constatives could be said to be true or false; performatives are, by contrast, felicitous or infelicitous. The utterance of a performative was thought by Austin to be not so much a saying of something as a doing of something. Thus, in his view, to utter the words 'I do' or 'I promise to be there,' in appropriate circumstances, is to bind oneself in marriage or to promise to be there, rather than to state that one is doing so. The precise drawing of this distinction gave Austin much trouble, and he eventually abandoned it.

Permutation argument: A permutation of a set of objects is any one-to-one function mapping that set on to itself. Under certain assumptions about the structure of a language, it can be shown that given one Interpretation (q.v.) or scheme of reference stipulations for the language, and given any permutation of its domain, there is an alternative, 'unintended' interpretation of the language based on that permutation, which makes quite different referential assignments to its singular terms and predicates, but which induces the same truth-values on the sentences of the language as does the given interpretation. This has been taken by some philosophers (especially W. V. O. Quine and Donald Davidson) to imply indeterminacy, or inscrutability, of reference, or (by Hilary Putnam) to raise insuperable difficulties for 'external' or 'Metaphysical' realism (q.v.).

Physical externalism: see **Natural kind externalism**

Physicalism: The thesis that reality is nothing more than physical reality, and hence that physical science can, in principle, give a complete description of all that there is. The doctrine is widespread, and influential in the philosophy of language in so far as widely conceived as enjoining some form of reductive or reconstructive account of those areas

of discourse – about values, or semantics, or intentional psychology, or modality, for instance – whose subject-matter does not appear to be physical in any straightforward sense. Physicalism has been a driving force in Quine's philosophy of language in particular, and a target of Putnam's writing since the mid-1970s.

Platonism: In the theory of meaning, this term is often applied to the view that the meanings of terms and sentences are (1) concepts and propositions which (2) are non-spatio-temporal entities known by non-perceptual intuition.

Possible world: A possible world is a way the world might be, a complete possible situation or state of affairs. The concept of a possible world has diverse formal and philosophical uses, and has been given very different philosophical explanations by different philosophers. In abstract formal semantics, possible worlds are primitive elements that are constituents of the models used to define the semantic values for expressions of the language of modal logic. Philosophers have appealed to them to formulate metaphysical theses and to give philosophical analyses of epistemological, semantic, and metaphysical concepts such as supervenience, counterfactual conditionals, dependence and independence of various kinds, potentiality, essence, information, obligation, and ability. According to some, possible worlds are literally worlds, universes parallel to our own; according to others, they are maximal properties that the world might have, or maximal propositions, or complex abstract structures whose elements are actual individuals, properties, and relations.

Principle of Charity: The Principle of Charity is a supposed important constraint, invoked by Davidson, on the interpretation of the thoughts of others. The Principle says that interpretation must proceed in such a way that the judgments attributed to the others come out, for the most part, as true. It is argued to follow from the idea that we can disagree with someone, that is, identify a thought of hers and label it false, only against a background of substantial agreement. This in turn is said to follow from Semantic holism (q.v.). Some philosophers take the Principle of Charity to be implausibly strong, and do not see why a person or persons should not, for example through the bad luck of being faced with many cases of misleading evidence, end up with beliefs which are largely false. Some philosophers, for this reason, prefer to see interpretation constrained by the Principle of Humanity (q.v.).

Principle of Humanity: The Principle of Humanity is preferred by some (e.g., Grandy and Lewis) to the Principle of Charity (q.v.) as a guiding constraint on interpretation. The Principle of Humanity says that we should interpret others as thinking and saying what we would have thought or said had we been in their circumstances, for example if we had had their sensory equipment, undergone their upbringing, been through their life experiences, and so on.

Privacy: As it is understood in the philosophy of mind, the term 'privacy' is used to mean the property of being knowable to one person only. Certain mental states or events, it can plausibly be thought, can be known only to the person in whose mind they take place; nobody else can know what they are like. Whether there are any private states in this sense, and if so which, and what makes them private, are central questions in the philosophy of mind and the theory of knowledge. In the philosophy of language the main questions about privacy are (1) whether the nature of speakers' private states can affect the meanings of their words, or whether meaning is constituted solely by publicly knowable features of speakers and their behavior; and (2) whether there could be a Private language (q.v.).

Private language: A private language is a language which a person uses to record thoughts about their own private states (see **Privacy**); it is often also understood to be a language which, in principle, only that person can understand. The most famous discussion of private language occurs in Wittgenstein' s *Philosophical Investigations*, §§242–258, the burden of which is that no such language is possible, since it would not satisfy the conditions under which terms can have a meaning, even a private one. Wittgenstein's introduction of the notion of a private language (*Philosophical Investigations*, §243) appears to use both the above definitions simultaneously; this may indicate a (contestable) assumption that the first entails the second.

Projectivism: A projectivist theory of a given region of discourse maintains that in casting its characteristic claims in assertoric or propositional style, we are not properly understood as attempting correctly to describe mind-independently constituted facts or states of affairs, but are instead 'projecting' our own feelings, attitudes, or other affective (as distinct from cognitive) psychological states onto the world. Hume's treatment of moral judgments (according to which morals are "more properly felt than judg'd of") and judgments of causal necessity (as expressive of a felt determination of the mind to infer effect from cause, rather than record some objective necessary connection) are often regarded as classic examples of projectivist theories. As the first example suggests, projectivist theories are often developments of Expressivist (q.v.) accounts of a region of discourse (see also **Quasi-realism**).

Proposition: A proposition is what is said in a speech act, and also the content of a mental act or attitude – for example, a belief or desire state, or a mental act of judgment. A theory that appeals to propositions usually begins by factoring a speech act into content and force. An assertion – for example, a statement that the window is closed – differs in force, but might have the same content as a request that the window be closed. Different theorists differ about what a proposition is, though it is usually assumed to be an abstract object explained in terms of a set of truth-conditions: propositions might be identified either with truth-conditions themselves, or with a structure that represents a recursive procedure for determining a set of truth-conditions.

Propositional attitudes and subdoxastic states: Propositional attitudes are states such as beliefs, desires, hopes, and wishes. The general form of a propositional-attitude ascription can be represented as follows: S j's that P, where "S" stands for the subject to whom the attitude is attributed (John, Jim), "j" for the type of attitude ascribed (belief, desire), and "P" for the informational content of the attitude (that Belhaven is brewed in Dunbar, that Raith Rovers sign Paul Gascoigne). Examples of propositional attitudes are thus John's belief that Belhaven is brewed in Dunbar, or Jim's desire that Raith Rovers sign Paul Gascoigne. Philosophers have attempted to delineate a related but distinct category of mental state, called subdoxastic states: these are like propositional attitudes in so far as they possess informational content, but different from propositional attitudes in so far as they are not ordinarily available to consciousness, and are inferentially insulated from the rest of their possessors' cognitive states: S. Stich, "Beliefs and subdoxastic states," *Philosophy of Science*, 45 (1978); M. Davies, "Tacit knowledge and subdoxastic states," in A. George (ed.), *Reflections on Chomsky* (1989). Philosophers such as Davies, who are impressed by the arguments of Evans – "Semantic theory and tacit knowledge," in S. Holtzmann and C. Leich (eds), *Wittgenstein: To Follow a Rule* (Routledge, 1981) – to the effect that states of tacit knowledge of semantic axioms cannot be propositional attitudes, have attempted to construe states of tacit knowledge as subdoxastic in this sense.

Public language: So called by contrast with Private language (q.v.), a public language is any language in which two or more speakers can communicate with each other. All existing natural languages may be presumed public languages in this sense. The philosophical use and interest of this concept lies in the questions (1) whether the fact that a language is public may not rule out certain accounts of the meaning of its words, and (2) whether being a language at all may not necessitate being a public language. (See Chapter 11, MEANING AND PRIVACY.)

Quantifying in: In (extensions of) first-order logic, a sentence involves *quantifying into* a construction when there is a variable within the scope of the construction bound by an operator without. For example, the sentence

(1) $\forall x(Fx \rightarrow \Box Fx)$

involves quantification into the necessitation construction (the construction which maps a sentence S to '$\Box$S'), as the last 'x' in (1) is in the scope of the construction, and is bound by the initial quantifier, which is not.

One often speaks of quantification in natural language; an example of such is

(2) Each spy believed that the man next to him was a spy

when 'him' is anaphoric on 'each spy.' One may understand such talk in terms of regimentation – a sentence involves quantification into construction c if its regimentation involves quantification into c's regimentation. A first stab at a direct definition might be S involves quantification into c when it contains pronouns (or the like) within c, bound to or anaphoric on expressions which occur outside of c.

Quasi-realism: 'Quasi-Realism' is the name conferred upon a species of anti-realism by its principal proponent, Simon Blackburn. As applied to moral discourse, the quasi-realist maintains, with the Expressivist (q.v.), that to construe moral utterances as descriptive of moral facts or states of affairs is a philosophical error – such utterances are to be understood as expressive of moral feelings or attitudes which we project on to the world, rather than as aimed at recording aspects of an independently constituted moral reality. Blackburn's distinctive aim is to show that the absence of a special realm of non-natural properties or facts to render moral judgments true or false does not – as on an Error theory (q.v.) – entail that such discourse is inherently defective, and that we can quite properly, and consistently with anti-realist scruples and with a Projectivist (q.v.) theory of morality, present our moral sentiments 'in propositional style,' as if they were genuine judgments with truth-conditions.

Radical interpretation: To interpret an item, for example a sound, mark, or gesture, is to assign a meaning to it. When we hear a remark in a familiar language we usually interpret it easily in the light of our knowledge of the language and/or of the person speaking. But radical interpretation is the enterprise of working out the meanings of what we take to be some set of utterances, when we start with no prior semantic knowledge at all, such as information about the structure of the language, the meanings of any words, or the beliefs, interests, and so on of the speakers. It is closely related to the enterprise of Radical translation (q.v.) introduced by Quine; but it differs in that it is to issue not just in claims that a certain sentence (of the native language) and this sentence (of my language) are synonymous, but in actual statements of the meaning of the sentence in the native language. It is thought that reflecting on how we might establish semantic hypotheses from

non-semantic starting points could be a useful philosophical tool in throwing light on the metaphysics and epistemology of meaning.

Radical translation: The process of translating a foreign language in circumstances where no prior knowledge of its syntax, or the etymology and/or likely meaning of any of its expressions, can be assumed, and where no assistance is to be had from bilinguals. Thus the assumption is that the radical translator is restricted, at least initially, to data which exclusively concern the linguistic behavior of the native speakers of the foreign language. It is usually assumed, in addition, that the translator is able from the outset to identify natives' expressions of assent and dissent. It is an important assumption of Quine's philosophy of language that there cannot be more to meanings than can be detected under such constraints. (See also **Radical interpretation** and **Myth of the museum**.)

Referentialism: The term 'Referentialism' is used for the movement in the philosophy of language that rejects the Fregean doctrine that the content of a term (definite description, name, or indexical) is a mode of presentation or an identifying condition. Referentialists such as Marcus, Kaplan, Donnellan, and Kripke claim that, at least for names and indexicals, this is not so. In Chapter 38, THE SEMANTICS AND PRAGMATICS OF INDEXICALS, a pair of distinctions are made, assigning rather special meanings to some well-worn terms from the philosophy of language, to further clarify this thesis:

Denoting versus naming: An expression denotes when the rules of language assign specific conditions to the expression that an object must meet to be designated by it. We say the expression denotes the object that meets these conditions, if any. Expressions that denote are contrasted with those that name. The rules of language assign specific objects to names, rather than conditions.

Describing versus referring: A term describes if it denotes, and contributes the condition assigned to it by the rules of language, rather than the object denoted, to the content of statements containing it. Describing is contrasted with referring. A term refers if it contributes the object it designates (denotes or names) to the content of statements containing it. Given this terminology, we can say that referentialism is the doctrine that indexicals and names refer rather than describe: indexicals denote and refer, names name and refer.

Relative Identity Thesis: The Relative Identity Thesis is the thesis formulated by Peter Geach in "Identity," *Review of Metaphysics*, 21 (1967), that identity is relative. The thesis has several components. The most ambitious contention Geach puts forward is that absolute identity is inexpressible; a language may contain a predicate expressing indistinguishability by the predicates it contains, but no language can contain a predicate expressing indistinguishability *simpliciter*. Additionally, Geach maintains that identity under a sortal concept (*being the same* A where 'A' is a sortal term) need not entail indistinguishability even by all the predicates contained in a language in which such sortal-relative identity is expressed. Thus objects may be identical under one sortal concept, distinct under another.

Restricted versus unrestricted quantification: The notion of restricted quantification is a significant element in the package of ideas put forward by Peter Geach under the heading of 'relative identity' in "Identity," *Review of Metaphysics*, 21 (1967). It is an important part of his position that sortal terms, in subject position, are names, on a par with proper names; and he takes this to imply that where 'A' is a sortal term 'some A is F' is stronger than 'something is A and F,' and 'every A is F' is weaker than 'everything, if it is an A, is F.' If Geach's thesis that identity under a sortal concept need not be absolute identity is

accepted, the irreducibility of restricted quantification follows. Otherwise there is no argument for it.

Rigidity: Rigidity is a semantic property of expressions. Where e is an expression, let e-c denote the occurrence of e in the context c. e-c is rigid with respect to a class of points of evaluation (e.g., possible worlds, or times) just in case, for some x, the designation of e-c is x, and at every point of evaluation in which x exists, the designation of e-c is x, and e-c has no designation other than x at points of evaluation at which x does not exist. For example, the expression "I" when uttered by Frank is rigid with respect to the class of possible worlds, since in any possible world in which Frank exists, that occurrence of "I" designates Frank, and designates nothing else in worlds in which Frank does not exist. An expression can be said to be rigid just in case the denoting occurrences of it are.

The concept of rigidity has proved to be a useful tool in gaining an understanding of the complex semantical interactions between intensional operators and certain classes of expressions, such as names, indexicals, and pronouns. Rigidity is also important in the model theory of quantified intensional logic, where it is used as a restriction on variables.

S4 principle: The distinctive theorem schema of C. I. Lewis and C. H. Langford's system S4 of modal logic can informally be stated thus: if it is necessary that P, then it is necessary that it is necessary that P. This is expressed by the formula $\Box p \rightarrow \Box\Box p$. Readings of the symbol $\Box$ other than 'it is necessary that …' give what may also be described as S4 principles. For example, if $\Box$ is read as 'it is clear that …,' the result is the principle that if it is clear that P, then it is clear that it is clear that P, a principle to which Higher-order vagueness (q.v.) may provide counter-examples. In possible-worlds semantics the S4 principle corresponds to the condition that if a world z is possible from the standpoint of a world y, and y is possible from the standpoint of a world x, then z is possible from the standpoint of x, that is, relative possibility is transitive.

S5 principle: The distinctive theorem schema of C. I. Lewis and C. H. Langford's system S5 of modal logic can informally be stated thus: if it is possible that P, then it is necessary that it is possible that P. An equivalent schema is: if it is not necessary that P, then it is necessary that it is not necessary that P. This is expressed by the formula $\neg\Box p \rightarrow \Box\neg\Box p$. Readings of the symbol $\Box$ other than 'it is necessary that …' give what may also be described as S5 principles. For example, if $\Box$ is read as 'it is clear that …,' the result is the principle that if it is not clear that P, then it is clear that it is not clear that P, a principle to which Higher-order vagueness (q.v.) may provide counter-examples. In possible-worlds semantics, the S5 principle corresponds to the condition that if worlds y and z are possible from the standpoint of a world x, then z is possible from the standpoint of y. Given that relative possibility is reflexive, this is equivalent to the condition that it should also be both symmetric and transitive.

Second-order languages: see **First-order languages**

Semantic conception of vagueness: What distinguishes this view from the Ontological conception of vagueness (q.v.) is the claim that all vagueness arises in thought and talk, not in what is thought and talked about (in so far as it is not itself thought and talk). What distinguishes the semantic conception from the Epistemic conception (q.v.) is the claim that vagueness results in the failure to make a statement that is either true or false (and not both) in borderline cases. There is either no truth-value at all, or one of a non-standard kind, for example 'neutral,' 'true to degree 0.7,' or 'both true and false.' Such behavior may be attributed either to gaps and defects in the meanings of vague expressions, or to positive meanings of an alternative kind, for instance as given by prototypical examples

uncircumscribed by boundaries. Many different technical treatments of vagueness are consistent with the semantic conception. (See **Degree of truth**, **Supervaluation**.)

Semantic creativity and learnability: Speakers of a natural language display semantic creativity in so far as they are able to understand novel utterances, that is, utterances of sentences which they have never before encountered. For example, your understanding of "Napoleon's grandfather wore purple pyjamas" is (almost certainly) a manifestation of semantic creativity. A related idea is that of the learnability of natural languages: a natural language is said to be learnable when a speaker needs only explicit training with, or exposure to, a small part of the language, in order to secure competence with a larger and more extensive part.

Semantic externalism: Semantic externalism is the view that the propositional contents of at least some of the sentences uttered by a speaker fail to supervene on the intrinsic features of the speaker. The opposing view, semantic internalism, claims that the propositional contents *do* so supervene. Externalist views are typically argued for using thought experiments featuring internal duplicates, that is, speakers who by hypothesis share all intrinsic features, but whose utterances putatively possess different propositional contents. Sometimes externalist views are limited to some classes of expression such as natural kind terms (see **Natural kind externalism**), while other externalist views are more wide-ranging, appealing for example to the role of linguistic communities in determining content (see **Social externalism**).

Semantic holism: Semantic holism is the view that meaningful items (1) must necessarily occur as part of some whole, that is, a large set of such items, and (2) are such that the meaning of each item is somehow bound up with, constrains, and is constrained by, the meanings of the other items. It comes in various different versions (often not distinguished as sharply as would be useful) depending on whether the items are taken to be sentences and the whole the language of which they are elements, or whether the items are sentences and the whole a theory they jointly compose, or whether the items are thoughts and the whole a mind of which they are the contents.

Semantic internalism: see **Semantic externalism**

Semantic irrealism: Semantic irrealism is the thesis that there are no semantic facts and hence, in particular, no facts about what any expression means. Outrageous and even paradoxical as it may seem, this thesis has been seriously advanced and defended: most famously, perhaps, Saul Kripke takes it to be established by the skeptical argument he extracts from Wittgenstein's remarks on rule-following; and W. V. O. Quine draws a similar conclusion from his arguments for the indeterminacy of translation. Note that the semantic irrealist should not be seen as claiming that all expressions are meaningless, since the fact that an expression lacks meaning would be just as much a semantic fact as would the fact that it means such-and-such. Nor is the semantic irrealist necessarily committed to denying that semantic sentences have any proper use – though Quine certainly denies that they can have any part in serious science. The essential irrealist claim is that such sentences – in contrast with, say, sentences belonging to physics, for example, or geography – do not have meaning by being associated with truth-conditions. This leaves room to hold that semantic sentences have meaning in some other way, just as denying that there are moral facts leaves room to hold that moral utterances have meaning in some non-truth-conditional way. (See Chapter 26, INDETERMINACY OF TRANSLATION, for discussion of Quine's position, and Chapter 24, RULE-FOLLOWING, OBJECTIVITY, AND MEANING, for discussion of Kripke's.)

Semantic naturalism: Semantic naturalism is the view that semantic and intentional properties and relations, especially the properties of referring to something and of having such-and-such a truth-condition, are part of the natural order. They are instantiated in virtue of the instantiation of natural properties and relations. Natural properties and relations are ones that are reducible to (or realized by) properties and relations expressible in the vocabulary of the natural sciences (physics, chemistry, and biology) and the causal and nomological facts involving them. Most contemporary semantic naturalists think that the semantic properties of natural-language expressions can be explained in terms of the semantic properties of the mental states of users of the language, and that the semantic properties of mental states can be explained in terms of causal relations between them and various extra-mental items.

Semantic physicalism: see **Semantic naturalism**

Semantic value: A semantic value for an expression is an object that a semantic theory that interprets the language assigns to the expression. The term is intended to be abstract and neutral, leaving open what kind of objects a semantic theory uses to interpret its expressions. Semantic values for whole sentences may include the propositional content or thought expressed by the sentence, or a function that determines content as a function of context. The semantic values of words and other constituents of sentences will be whatever, according to the semantics, they must be to determine the semantic values of the expressions that contain them as constituents. In extensional theories, semantic values will be extensions.

Sense: Sense is that with which meaningful expressions are invested, and that in virtue of which they make reference to non-linguistic items (or, speaking more generally, have semantic values). Frege introduced the idea of the sense of an expression to be correlative with the idea of a speaker's understanding of the expression (see Chapter 2, MEANING AND TRUTH-CONDITIONS, especially §2). The sense of an expression is, then, the expression's *contribution* to the sense of any larger unit which can be used to say something true or false. In the limiting case of a sentence, the sense is the truth-condition. Or better (postponing commitment to senses as entities): to know what is the sense of a sentence is to know under what conditions the sentence has the semantic value of truth. Frege calls the sense of a sentence, which is very much the same thing as many philosophers have intended by "proposition," a *thought*. (The psychologistic overtones of the English word must be carefully kept out here. The thought is something public and non-psychological.)

Another special case of sense is that of the sense of a singular term. (Frege sets out from this case in "On sense and reference" in P. Geach and M. Black (eds), *Philosophical Writings of Gottlob Frege*, Blackwell, 1952.) A singular term has its sense by standing for – or presenting – its reference, which is an object. Different singular terms may present one and the same object by different "modes of presentation." Wherever this is the case, the singular terms in question will make different contributions to the overall sense of the various sentences in which they figure. To grasp the sense of a proper name fully and correctly, then, is to know which object the name stands for, and to know this in virtue of being party to a particular way of thinking of this object. Different ways may call into being different proper names with different senses, which may contribute to different thoughts about one and the same thing, and may thereby contribute to an explanation of the possibility of informative statements of identity. This feature of the Fregean scheme has attracted the skepticism of those who see problems in the individuation

of different ways of thinking of an item, and of those who see naming as irreducible to describing, and believe that different ways of thinking of a thing collapse into different descriptions of the thing.

Singular proposition: Suppose that assertion and belief are relations; call their objects *propositions*. Broadly Fregean views of propositions see them composed and individuated in terms of "ways of thinking" of objects and properties; broadly Russellian and Millian accounts posit *singular propositions*, whose identity is a function simply of the objects and properties they concern. A Fregean representation of the proposition that Fichte weeps, pairs a way F of thinking of Fichte and a way W of thinking of the set of weepers; the singular proposition may be represented by pairing Fichte with the property weeping.

As propositions determine truth-conditions, one difference between the views is truth-conditional. The Fregean proposition's truth presumably turns on the object, which F presents, having the property W presents; the singular proposition is true just in case Fichte weeps. If F can present something other than what it in fact does (or fail to present Fichte, though he existed), the propositions have different truth-conditions. A second difference is this: if 'Fichte weeps' expresses the Fregean proposition, presumably one must think of Fichte in way F to think that Fichte weeps; if it expresses a singular proposition, this is not so.

Social externalism: A version of semantic externalism, according to which the contents of many (or possibly all) linguistic expressions used by a speaker are partly determined by features concerning the other members of the speaker's linguistic community. The best known argument for social externalism is Tyler Burge's *arthritis* thought experiment. (See **Semantic externalism**.)

Sortal concepts: The notion of a sortal concept is the notion of a concept which conveys a criterion of identity and thus determines a type of object for which it makes sense to ask whether objects of the type are the same or different. Although the notion of a sortal concept can be illustrated by standard examples – 'man,' 'gold,' 'number,' and 'direction' stand for sortal concepts – it is controversial how it is to be explained. Geach's view, in "Identity," *Review of Metaphysics*, 21 (1967), which is part of the package he offers under the title of 'relative identity,' is that predicates expressing sortal concepts like 'is a man' are semantically derivative from relational predicates expressing equivalence relations, like 'is the same man as': 'is a man' must be understood as 'is the same man as something' just as 'is a brother' must be understood as 'is a brother of someone.' This view is opposed by Michael Dummett in 'Does quantification involve identity?' in H. A. Lewis (ed.), *Peter Geach: Philosophical Encounters* (Kluwer, 1991), who argues that in the case of many sortal predicates, such as 'is a number,' they are rather to be understood as derivative from functors, for example 'the number of ….' Whatever the correct way to understand the notion of a sortal concept, it is generally accepted that both Mass terms (q.v.), which provide a criterion of identity but no principle for counting, and count nouns, which provide both, are sortal terms.

Speaker-meaning: A statement of the form: 'By uttering x, U meant such-and-such' aims to report what an agent meant$_{nn}$ (see **Natural and non-natural meaning**) by doing something (perhaps uttering certain words) on a particular occasion. This will be an instance of speakers' occasion-meaning$_{nn}$. By contrast, 'U means such-and-such by x' would ordinarily be used to say something about what U typically means$_{nn}$ by x, whenever she utters x – this will be an example of speakers' 'timeless' meaning, in Grice's terminology.

Speakers' occasion-meaning is the analysandum concept in the Gricean analysis of meaning. It is what speakers mean that is analyzed in the first instance. In Grice's approach, one builds up to the concept of linguistic meaning from that of speaker-meaning. The priority of speaker-meaning in this approach is evidence that the concept of meaning that Grice is concerned to analyze is somewhat *wider* than linguistic meaning.

Stimulus synonymy: Quine's behavioristic, non-normative surrogate for synonymy as more ordinarily conceived. A pair of sentences are stimulus-synonymous just in case the same stimuli as provoke assent to (or dissent from) the one provoke assent to (respectively, dissent from) the other; a pair of sub-sentential expressions are stimulus-synonymous just in case any sentence containing an occurrence of the one is stimulus-synonymous with the result of replacing that occurrence by one of the other.

Strict implication and equivalence: A statement A strictly implies a statement B if and only if it is necessarily true that if A then B (i.e., if and only if $\Box (A \rightarrow B)$, where '$\rightarrow$' is the material or truth-functional conditional). A and B are strictly equivalent if and only if they strictly imply each other (equivalently, if and only if $\Box (A \leftrightarrow B)$, where '$\leftrightarrow$' is the material or truth-functional biconditional).

Subject-matter: What a sentence or piece of discourse is about. This relates not only to the objects mentioned but also to the facts that might bear upon the truth or falsity of the sentence or discourse. Subject-matter in this latter sense might be represented by an equivalence relation on worlds or by a suitable closed set of candidate truthmakers; and the notion of subject-matter has played a significant role in the development of truthmaker semantics. (See Chapter 22, TRUTHMAKER SEMANTICS.)

Substitutional quantification: To understand "$(\exists x)Fx$" substitutionally is to understand it as true iff there is some name (say *n*) which can be substituted for the "x" in "Fx" such that the resulting sentence F*n* is true. This contrasts with the more common objectual understanding of "$(\exists x)Fx$," whereby it is true iff there is some object which is F. If the only object or objects which are F lack names, "$(\exists x)Fx$" will be true on the objectual reading but false on the substitutional. This difference will disappear if one extends the substitutional account to include new names, arguing perhaps that any object can be *given* a name. That, however, looks suspiciously like reducing substitutional quantification to objectual after all. The substitutional account may seem to help with "Whatever the Pope says is true": for any value of s, if the Pope says "s," then s. But it must not be allowed to disguise the problem of whether "s" is functioning in two different ways here. A decision to read the quantifier substitutionally does nothing by itself to explain the relation between the two occurrences.

Substitutivity, principle of: see **Leibniz's Law**

Superassertibility: This is a notion proposed originally by Crispin Wright as an anti-realistically acceptable replacement for the realist notion of Evidence-transcendent truth (q.v.). It is superassertible that P if and only if there is, or can be, warrant to assert that P, and some warrant to assert that P would survive arbitrarily close scrutiny of its credentials and arbitrarily extensive increments to, or other improvements upon, our state of information.

Supervaluation: Most generally, a supervaluation is a semantic property defined by quantification over valuations. The idea seems first to have been used in connection with philosophy of science, the name in connection with Liar paradoxes: for the history, see Williamson, *Vagueness* (Routledge, 1994), §5.2. In connection with vagueness, the valuations are classical assignments of sets to predicates ("sharpenings"); admissible valuations

meet various constraints designed to ensure that between them they represent the meaning of the predicate, even if it is vague. (So, e.g., an admissible valuation does not assign to the extension of the predicate something to which, intuitively, it definitely does not apply.) Truth (or "supertruth") is defined as truth-upon-all-admissible-valuations, and falsehood as falsehood-upon-all-admissible-valuations. This leaves room for the possibility, supposedly indicative of vagueness, of sentences which are neither true nor false.

Supervenience: The basic idea is that one range of facts supervenes upon another (the base or subvening facts) iff there could be no differences among the supervening facts without a difference in the subvening ones. When it is said that meaning supervenes upon use, the idea is that there could not be two communities who count as speakers of different languages unless there were differences in how each used its language. In serious discussion, some account must at once be given of "use," else the claim is trivial. (For example, it is not very controversial that the meaning of a declarative sentence supervenes on what it can be correctly used to say.) The slogan is often associated, historically, with behaviorist views in semantics: those which regard use as capable of being specified wholly behavioristically.

Tacit knowledge: Philosophers of language have invoked this notion in attempts to explain the Semantic creativity and learnability (q.v.) of natural language. The main idea is that if speakers of a language can be credited with tacit knowledge of a compositional semantic theory for their language (see **Compositionality**), we will have an explanation of semantic creativity (since the theory the speaker tacitly knows has the resources to generate a meaning-specifying theorem for the sentence uttered in the novel context) and an explanation of learnability (since the theory tacitly known can generate meaning-specifying theorems for a wide range of sentences on the basis of a narrower range of semantic axioms). Philosophers disagree as to the nature of states of tacit knowledge; in particular, they disagree as to whether they should be construed as *bona fide* propositional attitudes – see M. Dummett, "What is a theory of meaning? (II)," in G. Evans and J. McDowell (eds), *Truth and Meaning* (Oxford University Press, 1976) – or as mere dispositional states – see G. Evans, "Semantic theory and tacit knowledge," in S. Holtzmann and C. Leich (eds), *Wittgenstein: To Follow a Rule* (Routledge, 1981) – or as subdoxastic information-containing states – see M. Davies, "Tacit knowledge and the structure of thought and language," in C. Travis (ed.), *Meaning and Interpretation* (Blackwell, 1986).

Theory of meaning: As it appears in discussions by philosophers of language, this phrase may be taken in at least two ways. In the more general of the two senses, it denotes a theory dealing with language in general, which attempts to analyze and elucidate the concept of meaning. In this sense, it can be applied to attempted analyses or conceptual elucidations of what it is for an item to have meaning, as for example in Grice's linkage of linguistic meaning with speakers' intentions or in verificationist-style accounts which insist that what we can think, and hence mean, is importantly constrained by what we can know (see **Epistemic conception of meaning**). In the more specific sense it denotes a theory dealing with a particular language, which generates a theorem specifying the meaning of each well-formed declarative sentence of that language. Philosophers disagree about the nature of these theorems (often called "meaning-specifying theorems"): some take them to be statements of sentences' truth-conditions (Davidson), while others take them to be statements of sentences' conditions of warranted assertibility (Dummett).

Theory of truth, Tarski-style: The phrase 'a Tarski-style theory of truth' is used to describe an assignment of semantic properties to words and constructions which enables us,

given a specification of a sentence as built from certain words by certain constructions, to work out a biconditional stating truth-conditions of that sentence. Tarski himself insisted, for his purposes of giving the so-called semantic theory of truth, that the theory should issue in statements of truth-conditions in which the sentence which gives the truth-conditions has the same meaning as the sentence whose truth-conditions are given. (In the case where the metalanguage includes the object language, this results in the demand that the output of the theory should be theorems like the famous '"Snow is white" is true iff snow is white.') But the idea of a 'Tarski-style theory of truth,' as invoked, for example, by Davidson in the context of his project of Radical interpretation (q.v.), abandons that requirement; the idea is to use the formal apparatus devised by Tarski (e.g., of connectives or quantifiers) for a different purpose. (See also **Compositionality**.)

Things: There is a very weak sense of the term 'thing' according to which it is trivially true that *everything* is a thing. In this sense, any item which a system of Ontology (q.v.) acknowledges as existing at all may be accounted a 'thing' in that ontology. But for most purposes the term 'thing,' or 'object,' is used in a more robust sense, in which its application is restricted at least to the class of entities possessing well-defined identity-conditions, and hence to Kinds (q.v.) of entity for which Criteria of identity (q.v.) may be stated. Sometimes, however, 'thing' is used in an even more narrow sense than this, to refer to concrete, physical occupants of space which persist through time (otherwise called 'continuants') – a sense which excludes both Abstract objects (q.v.) and such physical entities as events. Clearly, if confusion is to be avoided in the use of the word 'thing,' care must be taken to indicate which of these senses is in operation.

Thought: see **Sense**

Timeless meaning: Timeless meaning is the meaning our utterances have when they are not tied to a particular occasion of utterance. Linguistic meaning is an instance of timeless meaning. If one takes it that linguistic meaning is necessarily structured (as philosophers do), then it is possible to have timeless meaning that is not linguistic. A system of communication based on (unstructured) gestures would be an example. Most – though not all – Griceans propose to build up to the notion of timeless meaning by adding the concept of convention to the analysis of Speaker-meaning (q.v.).

Tokens: Consider this list: philosophy, art, history, philosophy. Are there three or four words on the list? Three types appear, but four tokens; there are two tokens of the type "philosophy." Sometimes "token" is used for a particular act of uttering an expression of a given type, but more often it is used for the object that is produced by such utterances: the particular ink marks on a page, or the burst of sound that travels through the air. In this volume (see Chapter 38, THE SEMANTICS AND PRAGMATICS OF INDEXICALS) "token" is used in the second way, and "utterance" is reserved for acts. In this usage, a token is an effect of an utterance.

Travis cases: A Travis case (named after Charles Travis) is an imagined (or real) scenario where tokens of a linguistic type may have varying truth-values over a fixed context, even though the type is unambiguous and contains no indexical items. The putative consequence of the coherence of such scenarios is that meaning does not determine truth-value even with all relevant parameters and indexical factors fixed. Consider an utterance of 'The leaves are green' in a scenario where the relevant leaves are painted green. The crucial intuition is that the utterance may be read as true or false depending on a divergence between speakers' non-linguistic interests or purposes. A photographer, say, may happily take the sentence to be true, for she is only concerned with the surface

properties of the leaves, whereas a botanist is concerned with the natural state of the leaves, not merely how the leaves appear. Many of the disputes concerning such cases, engaged in by both linguists and philosophers, pertain to their significance for traditional compositional truth-conditional semantics, for such cases appear to show that fixing the meanings of the words in a sentence and the semantic significance of the syntax of the sentence is not sufficient to fix truth-conditions for the sentence, even relative to context/circumstances.

Truth-bearers: There has been much dispute over what the (primary) bearers of truth are. Candidates have included sentences, statements, judgments, propositions, thoughts, and beliefs. The dispute has been partly verbal. A sentence can be true, but evidently what is true is the sentence *as* used on a particular occasion, to convey a particular message; in other words, to make a particular statement or to express a particular proposition. Hostility to statements and propositions has often arisen from thinking they must be entities of a peculiar metaphysical kind. Some defenders of propositions have indeed thought of them like that, but without such commitment one can legitimize talk of propositions if one can specify the conditions under which two utterances express the same proposition. Following Quine, some have maintained this cannot be done – a serious objection, if correct, but at least counter-intuitive. The objection to taking thoughts, judgments, or beliefs to be primary truth-bearers is that they are subjective mental occurrences. But again, while beliefs (etc.) are held by individuals, there seems a good sense in which two people can be said to share the same belief – which they might voice by uttering sentences expressing the same proposition.

Truth-condition: see **Sense**

Truthmaker: An object in the world (such as a fact or state of affairs) that makes a sentence true. The truthmaker can be: exact, wholly relevant to the sentence it makes true; inexact, partially relevant to the sentence; or loose, merely standing in a modal relationship to the truth of the sentence. Truthmakers are of importance, both in metaphysics as a guide to the structure of the world and in semantics as a guide to meaning; and the exact form of truthmaking has recently been thought to be especially important in this regard.

Underdetermination of empirical theory by data: The contention that any body of empirical evidence for a particular theory will be compatible with alternatives to that theory, and hence cannot constrain the selection of any particular one among a range of alternative empirical theories. The thesis is uncontentious if one restricts attention to finite accumulations of evidence. In Quine, however, it is generalized to cover *all possible* empirical data. A stronger version yet contends that even all possible data *plus* best scientific methodology – proper canons of simplicity, economy, …, integration, and so on in theory construction – never determine one particular empirical theory as uniquely best. The Underdetermination Thesis is the main premise for Quine's principal argument for the Indeterminacy of translation (q.v.).

Universals: Universals are the (supposed) referents of general terms, such as 'red,' 'car,' and 'planet,' conceived as entities distinct from any of the Particulars (q.v.) which instantiate them. As such, they are Abstract objects (q.v.). Whether such entities really exist has long been a matter for heated debate, those denying their existence usually being called 'nominalists' and their opponents 'realists.' There are two main schools of realism: Aristotelian or 'immanent' realism, which holds that universals exist 'in' particulars, and accordingly cannot exist if uninstantiated; and Platonic or 'transcendent' realism, which holds that universals exist 'separately' from particulars, and consequently may exist even if they have no instances.

Use theory of meaning: Use theories of meaning are sometimes referred to as communication or pragmatic theories. Grice's account of meaning is an example of a use theory. Such theories of meaning have their roots in the work of J. L. Austin (the idea that meaning is to be associated with use is also a theme in the later writings of Wittgenstein). Such approaches to meaning connect the concept primarily with the actions of speakers. The approach looks at the phenomenon of meaning quite widely, taking linguistic meaning to be a particular instance of the phenomenon. As a result, structure is accorded less emphasis.

Verificationism: The verifiability criterion of meaningfulness is the claim that a meaningful sentence is one which is capable of being verified or falsified. Even those who would generally find no inclination to hold such a view find themselves disposed to think that, if our vague predicates really do draw sharp boundaries, it would have to be possible for us to tell where these boundaries fall. Such theorists would do well to justify the specific view about vagueness on some basis other than the general verificationist claim, for this latter is now rarely thought defensible, at least in the crude form given here.

A verificationist theory of meaning holds, in general terms, that understanding a sentence consists in grasping what information states would verify it. An information state verifies a sentence just if a person in that state is warranted in asserting it. Strict forms of verification further require that the verifying information state should be indefeasible.

A verificationist view of truth holds that truth is verifiability. A sentence is true if and only if it is verifiable, that is, if and only if there is evidence warranting its assertion.

Wide cosmological role: One of several features or marks proposed by Crispin Wright, in virtue of which realism concerning the subject-matter of a given discourse whose characteristic statements qualify for at least Minimal truth (q.v.) may be maintained. A discourse exhibits wide cosmological role if the facts recorded in its characteristic claims have a role to play in explanations of further facts of other kinds, beyond facts about our beliefs and other attitudes, and can figure in such explanations other than as objects of those attitudes. It might be contended that while moral, or modal, beliefs, for example, are apt to figure in explanations of our actions, desires, and other beliefs, moral or modal facts themselves exert no influence on other goings-on; in contrast, facts about the primary qualities of bodies, for example, exert causal influence in the world at large. To the extent that this is so, we might think that it justifies a kind of realism about facts of the latter kind which is unwarranted in regard to the former. (See **Cognitive command**, **Euthyphro contrast**.)
